What Firdousi and the court-poets of Sultan Muhammad and Safarîs had commenced, what Abû 'l-Farâj Rûmî of Lahore and Mas'ûd b. Sa'id b. Sâlûm (under Sultan Ibrâhîm, 1089–1099) had successfully continued, reached its perfection in the famous group of panegyrist who gathered in the first half of the 6th century of the Hârân, and formed the throne of Sultan Sinjar, and partly formed that of his great antagonist, Atsîz, shah of Khwârizm. This group included Abû Shâbir, who was drowned by order of the prince in the Oxus about 1145 (540 A.H.), and his pupil Jâhârî, the goldsmith of Bokhârâ; Abî Mu'izzî, the king of poets at Sinjar's court, killed by a stray arrow in 1147 (542 A.H.), Rashîd Wa'twât (the Swallow), who died in 1182 (578 A.H.), and left, besides his Kâshâs, a valuable treatise on poetry (Hadî'î-eshîshî) and a metrical translation of the sentences of 'Ali, 'Abd-al-wâsî Jâhâl, who sang at first, like his contemporary Hasan Ghaznavî (d. 1165; 565 A.H.), the praise of the Ghaznavî shah Bâhrâm, but afterwards bestowed his eulogies upon Sinjar, the conqueror of Ghazni; and Aûhad-uddîn Anwarî, the most celebrated Kâshâ-writer of the whole Persian literature. Anwarî (died between 1180 and 1191; 585 and 587 A.H.), who in early life had pursued scientific studies in the madrasa of Tûs, and who ranked among the foremost astronomers of his time, owes his renown as much to the inexhaustible store of poetical similes and epitheta orantia which he showered upon Sinjar and other royal and princely personages, as to his cutting sarcasms, which he was careful to direct, not against individuals, but against whole classes of society and the cruel wrong worked by an inexorable fate—thus disregarding the opinion of Firdousî, whose attack upon Sultan Muhammad for having cheated him out of the reward for his epos is the oldest and most finished specimen of personal satire. This legitimate branch of high art, however, soon degenerated either into the lower forms of jest and travesty—for which, for instance, a whole group of Transylvanian and Ruthenian poets (d. 1774; 560 A.H.)—and his contemporaries, Abû 'l-'Abbâs Shamsûnî of the town, Lâmi of Bokhârâ, and others gained a certain literary recognition—or into mere comic pieces and jocose poems under the trivial designation of the "Pleasanties" (Hadî'îyyât) and the humorous stories of the "Mouse and Cat" and the "Stone-cutter" (Sunlarâsh) by Abû Sa'id Zâkânî (d. 1370; 772 A.H.). Anwarî's greatest rival was Khâkânî (d. 1190; 595 A.H.), the son of a carpenter in Shirvân, and paraglyphist of the shâhs of Shirvân, usually called the Findar of the East. To European taste only the shorter

epigrams and the double-rhymed poem Tawâfît-irâkânî, in which Khâkânî describes his journey to Mecca and back, give full satisfaction. Among his numerous contemporaries and followers may be noticed Abu 'l-ud-dîn Ballâkhânî (d. 1186; 594 A.H.), Zâhid Fârîyâbî (d. 1202; 598 A.H.) and Ahtîr Ahtâkârî (d. 1218; 625 A.H.)—all three great panegyrists of the sultâns of the Great Khans of Azerbaijan, and especially of Sultan Kizil Arslân—Kamal-uddîn Işfahânî, tortured to death by the Moguls in 1337 (635 A.H.), who sang, like his father Jamâl-uddîn, the praise of the governors of Ispahan, and gained the epithet of the "creator of fine thoughts" (Khalâ'-u'l-umânî); and Sâîf-uddîn Işfârânî (d. 1267; 666 A.H.), a favourite of the shâhs of Khwârizm.

Frutilous as the 6th and 7th centuries of the Hârân were in panegyrics, they attained an equally high standard in didactic and mystical poetry. The origin of both can again be traced to Firdousî and his time. In the ethical and Mystic reiterations, wise maxims and moral exhortations—Poetry, scattered throughout the Shahnama the didactic element is plainly visible, and equally plain in it are the traces of that mystical tendency which was soon to pervade almost all the literary productions of Persian genius. But the most characteristic passage of the epos is the mysterious disappearance of Shâh Kaikhoosrau, who suddenly, when at the height of earthly fame and splendour, renounces the world in utter disgust, and, carried away by his fervent longings for an abode of everlasting tranquillity, vanishes for ever from the midst of his companions. The first Persian who employed poetry exclusively for the illustration of Sûfî doctrines was Firdousî's contemporary, the renowned sheikh Abû Sa'id b. Abû l-Khair of Mahana in Khurâsân (698–1049; 507–640 A.H.), the founder of that specific form of the rubâ'i which gives the most concise expression to religious and philosophic aphorisms—a form which was further developed by the great free-thinker Omar b. Khayyâm (q.v.), and Aûhad-uddîn Kîshâ (d. 1307; 707 A.H.). The year of Abû Sa'id's death is most likely that of the first great didactic mathnawi, the Rûshân, a'dînâ, or "Book of Enlightenment," by Nâşîr Khosrâu (q.v.), a poem full of sound moral and ethical maxims with slightly mystical tendencies. About twenty-five years later the first theoretical handbook of Sûfism in Persian was composed by Abû l-Khair al-Jâllâl al-Hujjâ'î in the Kashf-ul-mahjûb, or "Revelation of Hidden Things," which treats of the various schools of Sûfis, their teachings and observances. A great saint of the same period, Sheikh Abdallah Ansârî of Herît (1006–1080; 406–481 A.H.), assisted in spreading the pantheistic movement by his Munâjât or "Invocations to God," by several prose tracts, and by an important collection of biographies of eminent Sûfis, based on an older Arabic compilation, and serving in its turn as groundwork for Jâmi's excellent Nafaqat-ul-ulams (completed in 1478; 883 A.H.). He thus paved the way for the publication of one of the earliest textbooks of the whole sect, the Hadî'î-ethnikhati, or "Garden of Truth" (1350; 525 A.H.), by Hâshîm Sanâ'î of Ghazni, to whom we have already referred as the unrivalled master in spiritual knowledge. As the most uncompromising Sûfis appear the greatest pantheistic writer of all ages, Jâliî ud-dîn Rûmî (1207–1273; 616–672 A.H.; see RûMî), and his scarcely less renowned predecessor Fârid ud-dîn 'Attar, who was slain by the Moguls at the age of 114 lunar years in 1230 (627 A.H.). This prolific writer, having performed the pilgrimage to Mecca, devoted himself to a stern ascetic life, and to the composition of Sûfî works, partly in prose, as in his valuable "Biography of Eminent Mystic Divines," but mostly in the form of mathnawis (upwards of twenty in number), among which the "Birds of Dawn," the "Book of the soul's counsels," and the Manâjût-afîrât, or "Speeches of Birds," stand in the first rank. In the latter an allegorical poem, interspersed with moral tales and pious contemplations, the final absorption of the Sûfî is the duty is most ingeniously illustrated. In strong contrast to these advanced Sûfis stands the greatest moral teacher of Persia, Sheikh Sa'idî of Shirzâ (died about 110 lunar years old in 1322; 691 A.H.; see Sa'idî), whose two best known works are the Bûstân, or "Fruit-garden," and
the "Gulistan," or "Rose-garden." However, both have found comparatively few imitations—the former in the Dastārnāma, or "Book of Exercises" of Mīraddresses; the latter in the Sa'dī.

(d. 1230; 720 A.H.) in the Duh Būb, or "Ten Letters," of Kātībī (d. 1434; 838 A.H.), and in the Gulār, or "Rose-bower," of Hairātī (murdered 1534; 961 A.H.); the latter in Mu'in-uddīn Juwainī's Nigārīstān, or "Picture-gallery" (1335; 735 A.H.) and Jāmī's Bahārīstān, or "Spring-garden" (1487; 802 A.H.); whereas an innumerable host of purely Sūfī compositions followed in the wake of Sanā'Tī's, 'Atṣarī's and Jelāl ud-dīn Rumi's mathnawīs. It will suffice to name a few of the most conspicuous.

Further Sūfī Works. Lamō'ūl, or "Sparks," of 'Irīlī (d. between 1289 and 1307; 686 and 700 A.H.), the Žād-ul-mas'ūsfārīn, or "Friends of the Wayfarers," by Husnī (d. 1218; 1138 A.H.), the Gul data, or "Rose-bed of Mystery," by Maḥmūd Shabi tārī (d. 1320; 720 A.H.), the Jām-i-i-an, or "Cup of Jamshīd," by Abaruḏī (d. 1338; 738 A.H.), the Antūs-ul 'Arīfīn, or "Friend of the Mystics," by Kasīm (Qāsim)-Anwār (d. 1434; 837 A.H.), and others; 'As'sār-ul-Mū'ūshītūrīh, or "Sun and Jupiter" (1376; 778 A.H.), 'Arīdī's Gāwī and Qawāgin, or "The Ball and the Bat" (1438; 842 A.H.), Ḥusn-ul-Dil, or "Beauty and Heart," by Fattāhī of Nishāpur (d. 1448; 852 A.H.), Shāmī-ul-Pesāwūnī, or "The Candle and the Moth," by Ḥāfiz of Shirāz (1489; 894 A.H.), Shāhī-ul-Gūdū, or "King and Derīvāsh," by Ḥilālī (put to death 1339; 939 A.H.), Ḥādūd-dīn 'Amīrī's (d. 1621; 1030 A.H.) Nūn-ul-Hazītūrī, or "Bread and Sweets," Shīr-ul-Shakūr, or "Mill and Sugar," and many more.

During all these periods of literary activity, lyric poetry, pure and simple, had by no means been neglected; almost all the renowned poets since the time of 'Rūdgādī had sung in endless strains the pleasures of love and wine, the beauties of nature, and the Almighty power of the Creator; but it was left to the incomparable genius of Hādī (d. 780; 1181 A.H.; see Ḥāfiz) to give to the world the most perfect models of lyric composition; and the lines he had laid down were more or less strictly followed by all the ghazal-writers of the 9th and 10th centuries of the Hegira—by Sulamīn of Sāwā (d. about 1377; 779 A.H.), who excelled besides in Ḹāṣāda and mathnawī; Kamāl Khujandī (d. 1400; 833 A.H.), Hādī's friend, and protecté of Sultan Ḥosain (1374-1382 A.D.); Mahomed Ḥosaini Maghrībī (d. at Tabrīz in 1406; 800 A.H.), an intimate friend of Kamāl; Ni'mat-ullah Wali (d. 1431; 834 A.H.), the founder of a special religious order; Kasīm-i-Anwār (see above); Amīr Šāhī (d. 1433; 857 A.H.), of the princely family of the Sarbadārs of Sābēzvār; Bābātūn (d. 1512; 918 A.H.), who also wrote a romantic poem, Bahārān-ul-Būrāz; Bābā Fīghānī of Shirāz (d. 1519; 925 A.H.), usually called the "Little Hāfiz"; Nargāsi (d. 1531; 938 A.H.); Līsānī (d. 1534; 941 A.H.); who, himself was inspired by Imām of Isfahān, Muḥtāshām Kāshī and Wahshī Bāfīkī (all three died in the last decade of the 10th century of the Hegira); Ḥāfiz of Shirāz (d. 1535; 942 A.H.), author of the Siyr-ul-Halālī, or "Lawful Witchcraft," which, like Kātībī's (d. 1434; 838 A.H.) Majmā-ul-albārain, of the "Confluence of the Two Seas," can be read in two different metres; Nātī (d. 1610; 1010 A.H.), who wrote the charming romance of a Hindu princess who burned herself in Akbar's reign with her deceased husband on the funeral pile, called Sūd-ul-Gūdūz, or "Burning and Melting," &c. Among the immediate predecessors of Ĥāfiz in the 8th century of the Hegira, in which also Ibn Yāmīn, the great ʿiṣāt-writer,1 flourished, the highest fame was gained by the two poets of Delhi, Amīr Ḥasan and Amīr Khosravī. The latter, who died in 1425 (725 A.H.), two years before his friend, wrote a preface, the first of its kind, among all the Persian poets of India by the richness of his imagination, his graphic style, and the historical interest attached to his writings. Five extensive divāns testify to his versatility in all branches of lyric poetry, and nine large mathnawīs to his masterstip in the epic line. Four of the latter are poetical accounts of the reigns of

1 A ʿiṣāt or maḳaṭāʿa is a poem containing moral reflections, and differs from the ʿaṣāda and ghazal only by the absence of a maṭāʿ or initial dischist.
of Timur and his successors (see an account of the Zafarnama under PERSIAN LITERATURE), histories of sects and creeds, especially the famous Dabistan, or "School of Manners" (translated by Shen and Teyrion, Paris, 1843); and many local chronicles of Iran and Turkey. Next in importance to history rank geography, cosmography, and travel. For Persia, for instance, Hamdallah Mustaifi, who died in 1349, and the translations of Istakhrî's and Kazvinî's Arabic works, and the various tāhkiros or biographies of Shîfs and poets, with selections in prose and verse, from the oldest of A'ufi (about 1220) to the last and largest of all, the Makhzan-ul-khûrâb, or "Treasure of Marvellous Matters" (completed 1803), which contains biographies and specimens of more than 3000 poets. We pass over the well-stocked sections of philosophy, ethics and politics, of theology, law and Shîism, of mathematics and astronomy, of medicine (the oldest text being on which is the "Treasure of the shah of Khvâhistan" in 1216), of Arabic and Persian literature (LV. and LVI. volumes). The tâhkiros, or biographies, and lexicography, and only cast a parting glance at the rich collection of old Indian folk-lore and fables preserved in the Persian version of Kâlihâ u Dimmah (see RUDAGI), of Sinbadh-nâmâ, the Tûfûn-nâmâ, or "Tales of a Parrot," and others, and at the translations of standard works of Sanskrit literature, the epopees of the Râmâyana and Mahâbhârata, the Bhagavad-Gîtâ, the Yâga-Vashishtha, and numerous Pûrânas and Upanishâdhs, for which we are mostly indebted to the emperor Akbar's indefatigable zeal.

Mention should be made of a number of Persian translations of Persian literature are those of E. G. Browne, Literary History of Persia (2nd ed., 1902), and Hermann Ethé, in vol. ii. of Geiger and Kuhn's Grundriss der iranischen Philologie (Strasbourg, 1890); also in A'ufi's Takhvih (1864), of Persian Proverbs, and Perse, mystique, didactique et lyrique Poesie und das spätere Schrifttum der Perser (1885). See also P. Horn, Geschichte der persischen Literatur (1901). Concise sketches of Persian poetry are contained in Sir G. Ouseley's Biographical Notices of Persian Poets (1846); in G. L. Fligge's article in Ersh and Gruber's Allgemeine Encyclopädie (1842); in N. Bland's papers in the Journal of the Royal Asiatic Society, London, vol. ix.; and in C. A. Barbier de Meynard's Poésie et Parfes (Paris, 1877). Real mines of information are the catalogues of A. Spranger (Calculta, 1854); W. H. Monk (London, 1854); Fligge (3 vols., Vienna, 1865); and C. Rieu (3 vols., London, 1859-1863). For the first five centuries of the Hegira compare Ethé's editions and metrical translations of "Rûdgî's Vorläufer und Zeitgenossen," in Morgenländische Forschungen (Leipzig, 1875); of Kísa'i's songs, Ferdousi's lyrics, and of Shâh Rûdác's tableaux, in Herder's Morgenländische Forschungen, second Vol. (1875). See also Jacobi's Geschichte der persischen Literatur (1871). An interesting and valuable work is K. Perzschka's "Persische Literatur der hohen Morgenländischen Orientallisten-Kongresses (Berlin, 1882, pt. ii., first half, p. 48 seq.); H. Zöntgen's Chronique de Tabari (Paris, 1867-1874); Jurajni's Works (ed. by C. H. Grisez, Brussels, 1878); and Translations, comp. by C. H. Gra in Zeitschrift der morgenländischen Gesellschaft, xxii. (1875), and ii. (1876); and A. de K. Kasimirski's Specimen du vivâm den Mengscheh (Versailles, 1876). On Kâhihî, see N. de Khanoff's "Persian Lyricism," in the Vol. iv. and vol. v. p. 296 seq., and C. Salemann's edition of his rubâb, with Persian trans. (Petersburg, 1875); on Farid ud-dîn A'târ, S. de Sacy's edition of the Pandânama (Paris, 1819), and Gourin de Tassy's Manifâkouer (Paris, 1857); on the Gulistan-i-râs, E. H. Whiffeld's edition (London, 1880); and on Amir Khosrâu's mathnawis, the abstracts given in Eliot's History of India, iii. 524 seq. German translations of the Persian Yâmin were published by O. Schlechta-Wescher, Brüststücke (Vienna, 1865); omia, by C. L. Rosenzweig (Vienna, 1840); by F. Rücker, in Zeitschrift für die Kunste des Morgenlandes, vols. v. and vi., and Zeitschrift der d. morgenl. Gesellschaft, xxii. (1875), and xxiii. (1876); M. Weck erhauser (Leipzig, 1855, and Vienna, 1858); German translation of Shâh Rûdác's Mutamâbi, by C. L. Rosenzweig (Vienna, 1842), English by R. T. H. Griffith (London, 1881); French translation of Lâûtâ' ul Mahbûb, by E. de Revard (Paris, 1882), and German translation, by A. F. Germain (1879); and German translation of Hândî's "König und德rîsch," by Ethé, in Morgenländ. Stud. (Leipzig, 1862, p. 197 seq.). On the Persian drama, compare J. A. de Gobineau's Théâtre des lumières (Paris, 1867); Persische Gesellschaft, in Morgenländ. Stud., p. 174 seq. (1870) (H. E.).

PERSIGNY, JEAN GILBERT VICTOR FIALIN, DUCHE (1808-1872), French statesman, was born at Saint-Germain Lescopissade (Loire) on the 11th of January 1808, the son of a receiver of taxes. He was educated at Limoges, and entered the cavalry school at Saumur in 1826, becoming maréchal des logis in the 4th Hussars two years later. The share taken by his regiment in supporting the revolution of 1830 was regarded as insubordi nate, and next year Fialin was dismissed from the army. He became a journalist, and in 1833 became a strong Bonapartist, and in 1834 was named the claimant of the de Mouchard, said to be the son of Napoleon I. He planned the attempt on Strasbourg in 1836 and that on Boulogne in 1840. At Boulogne he was arrested and condemned to twenty years' imprisonment in a fortress, shortly afterwards commuted into mild detention at Versailles, where he wrote a book to prove that the Pyramids were built to prevent the Nile from siltling up. This was published in 1845 under the title, De la Destination et de l'utilité permanente des Pyramides. At the revolution of 1848 he was arrested by the provisional government, and on his release took a prominent part in securing the election of Louis Napoleon to the presidency. With Morny and the marshal Saint Arnaud he plotted the restoration of the empire, and was a devoted servant of Napoleon III. He succeeded Morny as minister of the interior in January 1852, and later in the year became senator. He resigned office in 1854, being appointed next year to the London embassy, which he occupied with a short interval (1858-1859) until 1860, when he resumed the portfolio of the interior. But the growing influence of his rival Rouher provoked his resignation in 1863, when he received the title of duke. A more dangerous enemy than Rouher was the empress Eugénie, whose marriage he had opposed and whose presence in the council chamber he deprecated in a memorandum which fell into the empress's hands. He sought in vain to see Napoleon before he started to take over the command in 1870, and the breach was further widened when master and servant were in exile. Persigny returned to France in 1871, and died at Nice on the 11th of January 1872.

See Mémoires du duc de Persigny (2nd ed., 1869), edited by H. de Larois d'Espagny, his former secretary; an eulogistic life, Le Duc de Persigny (1865), by Delarue; and Emile Olivier's Empire libéral (1865, &c.).

PERSIMMON, the name given to the fruits of Diospyros virginiana in the United States. The tree which bears them belongs to the order Ebenaceae, is usually from 30 to 50 ft. in height, and has oval entire leaves, and unisexual flowers on short stalks. In the male flowers, which are numerous, the stamens are sixteen in number and arranged in pairs, and the flowers are solitary, with traces of stamens, and a smooth ovary with one ovule in each of the eight cells—the ovary is surmounted by four styles, which are hairy at the base. The fruit-stalk is very short, bearing a subglobose fruit an inch or rather more in diameter, of an orange-yellow colour, and with a sweetish astringent pulp. It is surrounded at the base by the persistent calyx-lobes, which increase in size as the fruit ripens. The astringency renders the fruit somewhat unpalatable, but after it has been subjected to the action of frost, or has become partially rolled or "bletted," like a medlar, its flavour is improved. The fruit is eaten in great quantities in the southern states of America, and is also fermented with hops, corn-meal or wheat-bran into a sort of beer or made into brandy. The wood is heavy, strong and very close-grained and used in turnery. The tree is very common in the South Atlantic and Gulf states, and attains its largest size in the basin of the Mississippi. It was brought to England before 1829 and is cultivated, but rarely if ever ripens its fruit. It is easily raised from seed and can also be propagated from stolons, which are often produced in great quantity. The Chinese and Japanese cultivate another species, the Diospyros Kaki, of which there exist numerous ill-defined varieties. The fruits are larger than those of the American kind, variable in form, but have similar physiological properties. An astringent fluid, known as shibù, rich in tannin, is expressed from the green fruit and used in various industries. The tree is hardy in the south of England and in the Channel Islands.

PERSIS (mod. Fars, q.v.), the south-western part of Iran (Persia), named from the inhabitants, the Iranian people of the Parsa (Fars); their name was pronounced by the Ionians Persoi, with change from α to ε, and this form has become dominant.
in Greek and in the modern European languages. The natural features of Persis are described very exactly by Nearchus, the admiral of Alexander the Great (preserved by Arrian Indic. 40 and Strabo xv. 727). The country is divided into three parts, of very different character and climate: the coast is sandy and without much vegetation except date-palms; it has no good harbours, and the climate is very unwholesome; the population is scanty. About 50 m. from the coast rise the chains of the mountains, through which some steep passes lead into the interior valleys (called κοῖλον Ἡ φόρας, Strabo xv. 729), which lie about 5000 ft. above the sea. Here the climate is temperate, the country watered by many rivers and lakes, the soil fertile, the vegetation rich, the cattle numerous. These regions, which were thickly populated, form the real Persis of history. This land Persis," says Darius, in an inscription at Persepolis, "which Ahuramazda has given to me, which is beautiful and rich in horses and men, according to the will of Ahuramazda and myself it trembles before no enemy." The third part is the north, which belongs to the central plateau, still much higher, and therefore rough and very cold in the winter. Towards the north-west it borders on the Median district of Parætacene (about Isfahan); towards the north and north-east it soon passes into the great desert, of which only the oasis of Yezd (Istischai in Ptol. vi. 4, 2) is inhabited. In the east, Persis proper is separated by a desert (Laristan) from the fertile province of Carmania (Kerman), a mountainous region inhabited by a Persian tribe. To Carmania belonged also the coast, with the islands and harbours of Hormuz and Bijar, and the district east of the West Persian coast, called the region of the coast, and plains of Elam or Susiana. For the ancient topography cf. Tomaschek, "Beiträge zur historischen Topographie von Persien," in Sitzungsber. der Wiener Akademie, phil. Cl. cii. xviii. cxxi.

The Persians are not mentioned in history before the time of Cyrus; the attempt to identify them with the Parsua, a district in the Zagros chains south of Lake Urmia, often mentioned by the Assyrians, is not tenable. The Parsua are perhaps the non-Aryan tribe Πάρσων in northern Media, Strabo xi. 508. Herodotus i. 125, gives a list of Persian tribes: the Pasargadæ (at Murgab), Maraphip, Maspi, Panthialaei (in western Carmania), Derusiaei, Germanii (i.e. the Carmanians) are husbandmen, the Dahae (i.e. the "enemies," a general name of the rapacious nomads, used also for the Turanian tribes), Mardi, Dropici, Sagartii (called by Darius Asagara, in the central desert; cf. Herod. vii. 85) are nomads. The kings of the Pasargadæ, from the clan of the Achaemenidae, have become kings of the Elamitic district Anshan (probably in 596, cf. Cyrus). When, in 553, Cyrus, king of Anshan, rebelled against Astyages, the Maraphip and Maspian joined with the Pasargadæ; after his victory over Astyages all the Persian tribes acknowledged him, and he took the title of "king of Persia." But from then only the inhabitants of Persis proper were considered as the rulers of the empire, and remained therefore in the organization of Darius free from taxes (Herod. iii. 97). But Carmania, with the Sagartians, the Utiand (called by Darius Vautiya), and other tribes, formed a satrapy and paid tribute (Herod. iii. 93); the later authors therefore always distinguished between Carmania and Persis. Names of other Persian tribes, partly of very doubtful authority, are given by Strabo xv. 727, and Ptol. vi. 4 and 8.

The Persians of Cyrus (see Persis: Ancient History) were a vigorous race of husbandmen, living in a healthy climate, accustomed to hard labour, brave and upright; many stories in Herodotus (especially ix. 122) point the contrast between their simple life and the effeminate nations of the civilized countries of Asia. They were fiercely attached to their king, and have need of Zoroaster (cf. Herod. i. 131 sqq. and the inscriptions of Darius). When Darius had killed the usurper Smerdis and gained the crown, a new usurper, Vahyazdatha, who likewise pretended to be Smerdis, the son of Cyrus, rose in Vaitiya, but was defeated in two battles by Darius's generals and put to death (Beusthian inscription). Cyrus had built his capital with his palace and tomb, in Pasargadæ (q.v.). Darius founded a new city about 30 m. farther south on the left bank of the Pulvar, near its confluence with the Kur, which is a large torrent, on which his magnificent palace and that of his son Xerxes were built. As Pasargadæ was named after the tribe in whose district it lay, so the new capital is by the Persians and Greeks simply called "the Persians"; later authors call it Persepolis (q.v.), "the Persian city." Another Persian palace lay in Taqie, near the coast (Strabo xv. 728; Arrian Ind. 39; Dionys. Perig. 1060); Gabae, which Strabo mentions besides, is Isfahan in Parætacene and belonged already to Media.

Both in Persepolis and Pasargadæ large masses of gold and silver from the tribute of the subject nations were treasured, as in Susa and Ecbatana. But Persis lay too far off from the centre of the Asiatic world to be the seat of government. Like Arabia and similar countries, it could exercise a great momentary influence in history and produce a sudden change throughout the world; but afterwards it would sink into local insignificance. So the Persian kings fixed their residence at Susa, which is always considered as the capital of the empire (therefore Aeschylus wrongly considers it as a Persian town and places the tomb of Darius here). After the reign of Xerxes, Persis and Persepolis became utterly neglected, in spite of occasional visits, and even the palaces of Persepolis remained in part unfinished. But the national feeling of the Persians remained strong. When Alexander had won the victory of Arbela, and occupied Babylon and Susa, he met (in the spring of 307 B.C.) with strong resistance in Persia, where the satrap Ariobarzanes tried to stop his progress at the "Persian gates," the pass leading up to Persepolis. Here he set fire to the cedar roof of the palace of Xerxes as a symbol that the Greek war of revenge against the Persians had come to an end. Our best information tells us that he soon had the fire extinguished (Plut. Alex. 38); the story of Thais is a pure fiction, and we may well believe that he repented the damage he had done (Arrian vi. 30, 1).

Alexander had planned to amalgamate the former rulers of the world with his Macedonians; but his death was followed by a Macedonian reaction. Pecucetas, the new satrap of Persis, followed the example of Alexander, and thus gained a strong hold on his subjects (Diod. xiv. 48); nor did Seleucus, to whom the dominion of the east ultimately passed (from 311 onwards), disdain the aid of the Persians; he is the only one among the Diadochi who retained his Persian wife, Apame, daughter of Spitamenes. At the same time Seleucus and his son Antiochus I. Soter tried to introduce Hellenism into Persis. Of Greek towns which they founded here we know Alexandria in Carmania (Plin. vi. 107; Ptol. vi. 8, 14; Ammian. marc. 23, 6, 49), Laodicea in the east of Persia (Plin. 6, 115), Stasis, "a Persian town on a great rock, which Antiochus, the son of Seleucus, possessed" (Steph. Byz. s.) Antioch in Persis, founded apparently by Seleucus I., and peopled by Antiochus I. with immigrants called together from all Greece, as we learn from a psaphisma passed by "boulê and demos" of this town in 206 in honour of Magnesia on the Maeander (Kern, Inschriften von Magnesia am Maeander, No. 61 = Dittenberger, Oriental inscr. 233, where they are mentioned together with a great many Seleucid towns in Susiana and Babylonia, and compare Kern, No. 18 = Dittenberger, No. 231). An insurrection of the Persians against Seleucus (II.) is mentioned in two stratagems of Polyaeumus (vii. 39. 40). When in 221 Molon, the satrap of Media, rebelled against Antiochus III., his brother Alexander, pretender of Persia, joined him, but they were defeated and killed by the Persis. Persis received a part of the Seleucid empire handed down to Antiochus IV. Epiphanes, who at the end of his reign restored once more the authority of the empire in Babylonia, Susiana and Persis; perhaps a battle, in which the satrap Numenius of Mesene (southern Babylonia) defeated the Persians on the shore of Carmania on sea and land (Ptol. vi. 152), belongs to this time. But after the death of Antiochus IV. (164) the
Selectucid Empire began to dissolve. While the central provinces, Media and northern Babylonia, were conquered by the Parthians, Mesene, Elymais and Persia made themselves independent.

Persia never became a part of the empire of the Arsacids, although her kings recognized their supremacy when they were strong (Strabo xv. 728, 736). From the periphery of the Erythraean Sea 33-37 we learn that their authority extended beyond the shores of Carmania and the opposite coasts of Arabia. A Persian king, Artaxerxes, who was murdered by his brother Gosthros at the age of 93 years, is mentioned in a fragment of Isidore of Charax (Lucian, Macrobii, 15). Other names occur on their coins, the last of which are imitations of Selectucid coins, and were perhaps struck by local dynasts under their supremacy; most of the others above the king's head with the Persian tiara, and on the reverse a fire-altar with the adoring king before it, a standard (perhaps the famous banner of the smith Kavi, which became the standard of Iran under the Sassanids), and occasionally the figure of Ahuramazda; they were first explained by A. D. Mordtmann in Zeitschrift für Numismatik, iii., iv. and vii.; cf. Grundriss der iranischen Philol. ii. 456 sq. The legends are in Aramaic characters and Persian (Pahlavi) language; among them occur Artaxerxes, Darius (from a dynast of this name the town Darabjird, "town of Darius," in eastern Persia is named after its name), Narseh, Tiridates, Mazdak, Anzaram and others; the name Vahuburz seems to be identical with Oborzos, mentioned by Polyaenus vii. 40, who put down a rebellion of 3000 settlers (αροτορις) in Persis. From the traditions about Ardashir I. we know that at his time there were different petty kingdoms and usurpers in Persis; the principal dynasty is by Tabari called Bāzragni. The coins demonstrate that Hellenism had become quite extinct in Persis, while the old historical and mythical traditions and the Zoroastrian religion were supreme. There can be no doubt that at this time the true form of Zoroastrianism and the sacred writings were preserved only in Persia, whereas the Zoroastrianism of the Parthia, in the Indo-Scythian kingdoms of the east and in the great propagandist movement in Armenia, Syria and Asia Minor, where it developed into Mithraism) it degenerated and was mixed with other cults and ideas. So the revival of Zoroastrianism came from Persis. When Ardashir I. attempted to restore the old empire of Cyrus and Darius, and in 212 A.D. rose against the Parthian king, Artabanus, his aim was religious as well as political. The new Sassanid Empire which he founded enthroned the restored religion of Zoroaster (Zarathustra) on the whole of Iran.

The new capital of Persis was Istakh on the Pulwar, about 9 m. above Persepolis, now Hajjahbad, where even the pre-decessors of Ardashir I. are said to have resided. It was a great city under the Sassanids, of which some ruins are extant. But it shared the fate of its predecessor; when the empire was founded the Sassanids could no longer remain in Persis but transferred their headquarters to Ctesiphon.

PERSIUS, in full AULUS PERSIUS FLACCUS (A.D. 34-62), Roman poet and satirist. According to the Life contained in the MSS., Persius was a native of Volaterrae, of good stock on both parents' side. When six years old he lost his father, and his step-father died in a few years. At the age of twelve Persius came to Rome, where he was taught by Remmius Palmaeus and the rhetor Vergilius Flavinus. Four years later began a close intimacy with the Stoic Cornutus. In this philosopher's pupil Lucan, Persius found a generous admirer of all he wrote. Still in early youth he became the friend of the lyric poet Caesius Bassus, whilst with Thracea Paetus (whose wife Arria was a relative) he had a close friendship of ten years' duration and shared some travels. Seneca met later, and was not attracted by his genius. In his boyhood Persius wrote a tragedy dealing with an episode of Roman history, and a work, the title of which is rendered uncertain by corruption in our MSS. Pithou's generally accepted reading makes the subject that of travel; the excursions with Thracea however must have taken place after boyhood. The perusal of Lucullus revealed to Persius his vocation, and he set to work upon a book of satires. But he wrote seldom and slowly; a premature death (uitio stomachi) prevented the completion of his task. He is described as possessed of a gentle disposition, girlish modesty and personal beauty, and living a life of exemplary devotion towards his mother Fulvia Sisenna, his sister and her aunt. To his mother and sister he left a considerable fortune. Cornutus suppressed all his work except the book of satires in which he made some slight alterations and then handed it over to Bassus for editing.

It proved an immediate success. The prefixed dedication added a few words on what authority is, as generally with such sources, very doubtful. The Life itself, though not free from the suspicion of interpolation and undoubtedly corrupt and disordered in places, is probably trustworthy. The MSS. say it came to Bassus from the commonwealth of Valerius Probus; no doubt a learned edition of Persius like those of Virgil and Horace by this same famous "grammarius" of Berytos, the poet's contemporary. The only case in which it seems to conflict with the Saturae, however, is in its statement as to the death of Persius's father. The declaration of a suavaria in his presence (Sat. 3. 4 sq.) implies a more mature age than that of six in the performer. But peter might here mean "step-father," or Persius may have forgotten his own autobiography, may be simply reproducing one of his models. The mere fact that the Life and the Satires agree so closely does not of course prove the authenticity of the former. One of the points of Persius's greatness is his power to make each age and his own, and it does not seem to have been evoked from the works of Persius. It requires indeed a thoughtful reading of the Life before we realize how distinct is the impression it gives of a "bookish" youth, who has never strayed far, at least intellectually, from the home and environment of thought and expression. This course is not merely the picturesque drawn by the Satires. So much better does Persius know his books than the world that he draws the names of his characters from Horace. A keen observer of what was going on in his native city, he can not have missed even the smaller side of life (cf. e.g. such hints as Sat. iii. 110); he shows, however, none of Juvenal's undue stress on unsavoury detail or Horace's chief equally great gift of acceptance of human weaknesses. The sensitive, homebred nature of Persius shows itself perhaps also in his frequent references to ridicule, whether of great men by street gamin or of the cultured by Philistines.

The chief interest of Persius's work lies in its relation to Roman satire, in its interpretation of Roman Stoicism, and in its use of the Roman tongue. The influence of Horace on Persius can, I think, escape the silent reader of the Life, hardly even that of Lucilius. Not only characters, as noted above, but whole phrases, thoughts and situations come direct from him. The resemblance only emphasizes the difference between the caricaturest of Stoicism and its preacher. Persius strikes the highest note that Roman satire reached; in earnestness and moral purpose rising far superior to the political rancour or good natured persiflage of his predecessors and the rhetorical indignation of Juvenal, he seems a forerunner of the great Christian Apologists. From him we learn a lesson Seneca never taught, that wonderful philosophy could work on minds that still preserved the depth and purity of the old Roman gravitas. When the Life speaks of Seneca's genius and his great attracting Persius, it presumably refers to Seneca as the philosopher. Some of the parallel passages in the works of the two are very close, and hardly admit of explanation by assuming the use of a common source. With Seneca, Persius censors the style of the day, and imitates it. Indeed in some of its worst failings, straining of expression, excess of detail, exaggeration, he outbids Seneca, whilst the obscurity, which makes his little book of not seven hundred lines so difficult to read and is in no way due to great depth of thought, compares very ill with the terse clearness of the Epistolae morales. A curious contrast to this tendency is presented by his free use of "popular" words. As of Plato, so of Persius we fear that he emulated Sophron, the least of whom in the life of Persius (Lact. 41, 14), but we can at least recognize in the scene that opens Sat. 3. kinship with such work as Theocritus' Adonisuam and the Mimes of Herodas.

Persius's satires are composed in hexameters, except for the scansion of the short prologue above referred to, in which he half ironically asserts that he writes to earn his bread, not because he is inspired. The first satire is a long refutation of the false criticism that the satires are written as a reflection of the decadence of the national morals. The theme of Seneca's 114th letter is similar. The description of the rectator and the literary twaddlers after dinner is vividly natural, but an interesting passage which cites specimens of smooth verificatio
PERSON—PERSONALITY

255

and the languishing style is greatly spoiled by the difficulty of appreciating the points involved and indeed of distributing the dialogue (a not uncommon trick in Persius). The remaining satire handle in order (2) the question as to what we may justly and properly call an individual, and (3) the question of having a definite aim in life, (4) the necessity of self-knowledge for public men (cf. Plato’s first Alcibiades), (5) the Stoic doctrine of liberty (introduced by generous allusions to Cornutus’ teaching), and (6) the question of money. The Latin tells us that in Dublin the MSS. were not left complete; some lines were taken (presumably by Cornutus or Bassus) from the end of the work so that it might be quasi finitas. This perhaps means that a sentence in which Persius had indulged in a parade for a paragraph which he had not completed, had to be omitted. The same authority says that Cornutus deliberately blacked out an offensive allusion to the emperor’s literary taste, which Catullus has written in the MSS. in Sat. i. 121,

"auriculas asini quis non [for Mola rex habet]!" 

Traces of lack of revision are, however, still visible; cf. e.g. v. 176 (sudden transition from ambition to superstition) and vi. 37 (where criticism of Greek doctors has nothing to do with the context). The parallels to passages of Horace and Seneca are recorded in the commentaries: in view of what the Life says about Lucan, the verbal resemblance of Sat. iii. 3 to Plars. x. 163 is interesting. Examples of bold language or metaphor: i. 25, rupio teceer extort capricius, 60, lingue quantum sitiat canis; iii. 42, tautus pallete, 81, silentina rodunt; v. 92, vesiles auiae de pulmoni renov. Passages like iii. 87, 100 sqq. show elaboration carried beyond the rules of good taste. Popular words and phrases, graecia, munda mea, palpo, steloppos. Fine lines, e.g., in i. 116 sqq., ii. 6 sqq., 61 sqq., 73 sqq., 93 sqq.

AUTHORSHIP—The MSS. of Persius fall into two groups, the one representing two of the best of them, the other by that of Pithoetus, so important for the study of Juvenal. Since the publication of J. Bieger’s De Persii cod. pith. recte aestimando (Berlin, 1890) the text has been sufficiently controlled.

The important editions are: (1) with explanatory notes: Casaubon (Paris, 1605, enlarged edition by Dibner, Leipzig, 1833); O. Jahn (with the scheda and valuable prolegomena, Leipzig, 1843); Conning (with translation; 3rd ed., Oxford, 1903); H. L. Gildersleeve (New York, 1875); G. Némethy (Bud-Budetz, 1903); (2) with critical notes: Jahn-Bücheler (3rd ed., Berlin, 1893); S. G. Owen (with Juvenal, Oxford, 1902). Translations into English by Dryden (1667) (with Traquair’s notes); and, Holme (1890) and Henderson, e.g., in Marthia, Les Moralistes sous l’empire romain (5th ed., Paris, 1886); Nisard, Poetés latins de la décadence (Paris, 1834); Hirzel, Der Dialog (Leipzig, 1895); Saintsbury, History of Criticism, i. 248; Henderson, The Philosophers (Oxford, 1897); and Worterbuch (London, 1903); and the histories of Roman literature (especially Schanz, §§ 382 sqq.). A Bibliography of Persius, by M. H. Morgan (Cambridge, U.S.A., 1893).

PERSON, OFFENCES AGAINST THE. This expression is used in English law to classify crimes involving some form of assault or personal violence or physical injury, i.e. offences affecting the life, liberty or safety of an individual; but it is also extended to certain offences against morality which cannot technically be described as assaults. The bulk of the offences thus classified, so far as their definition or punishment depends upon statute law, are included in the Offences Against the Person Act 1861 (24 & 25 Vict. c. 100), and in the Criminal Law Amendment Acts of 1880 and 1884, and the Prevention of Cruelty to Children Act 1904. The classification in these statutes is not scientific: e.g. bigamy is within the act of 1861 (s. 57), and certain offences involving assault, e.g. robbery, are to be found in other statutes. The particular offences dealt with by the acts above named are discussed under their appropriate titles, e.g. abortion, assault, bigamy, homicide, rape, &c. In the Indian penal code most of the offences above referred to fall under the head “offences against the human body” (ch. xvi.). In his Digest of the Criminal Law Sir James Stephen includes most of these offences under the title “offences against the person, the conjugal and parental rights, and the reputation of the family” but this classification also has been found in the Scottish draft code of 1880 and adopted in the Queensland code of 1890. In working out this classification offences not involving assault are relegated to another and perhaps more appropriate title, “offences against morality.”

PERSONALITY (from Lat. persona, originally an actor’s mask, from personare; from analogies by analogy from πρόσωπον the Greek equivalent) 1, Walde, in philosophy and also in common speech to the identity or individuality which makes a being (person) what he is, or marks him off from all the rest. The term “person,” which is technically used not only in philosophy but also in theolog)' (Gr. πρόσωπον) to the three hypostases of the Trinity. It was first introduced by Tertullian, who implied by it a single individual; the Father, the Son and the Holy Ghost were three personae though of one and the same substance (nulias substantiae). The nature of this unity in difference exercised the minds of the early Christian theologians, and was the subject of many councils and official pronouncements, according as emphasis was laid on the unity or on the separateness of the persons. There was perpetual schism between the Unitarians and Trinitarians (see for example Sabellius). The natural sense of the word “person” is undoubtedly individuality; hence those who found a difficulty in the philosophic conception of the three-in-one naturally tended to lay emphasis on the distinctions between the members of the Trinity (see Heresy; Monarchianism; Logos, &c.). A further theological question arises in connexion with the doctrine of immortality (q.v.), and it is argued that immortality is meaningless unless the soul of the dead man is self-conscious throughout.

In philosophy the term has an important ethical significance. The Greek moralists, attaching little importance to individual citizens as such, found the highest moral perfection in the sub-ordination of the individual to the state. Man, as προσωπον φως, is good only when he is a good work. Subsequent ethical systems on the contrary laid stress on the moral worth of personality, finding the summum bonum in the highest realization of the self. This view is specially characteristic of the Neo-hegelian school (e.g. T. H. Green), but it belongs also in various degrees to all intuitional and idealistic systems. Utilitarian universalism hedonism and evolutionist ethics so far resemble the Greek theory that they tend to minimize the importance of personality, by introducing ulterior reasons (e.g. the perfection of the social organism, of humanity) as the ultimate sanctions of moral principles, whereas the intuitionists, by making the criterion absolute and absolute limit goodness to personal obedience to the a priori moral law. Still more important problems are connected with the psychological significance of personality. What is the origin and character of the consciousness of the self? The conscious-ness of the identity of another person is comparatively simple; but one’s own individuality consists partly in being aware of that individuality; a man cannot use the word “I” unless he is conscious of the unity of his “self,” and yet there is involved in the word “I” something more than this consciousness. In what does the unity of the “self” consist prior to its being recognized in consciousness; how does the consciousness arise? The answer to this problem is to be found—in so far as it can be found—in the subject-object relation, in the distinction between the external world and the subjective processes of knowing and willing which that relation involves. I will something, and afterwards perceive a corresponding change within the unity of my external world. Hence, we may suppose, arises the consciousness of a permanent self and not-self. It should be observed that self-consciousness varies according to the intellectual development, and the term “personality” is usually connected only with the self-consciousness of an advanced type, not, for example, with that of an animal. Even among human beings there is considerable difference. The most elementary form of human self-consciousness includes in the self not only the soul but also the body, while to the developed civilised self it is applied only to the part of the external world which is apprehended objective. Finally it is necessary to refer to the Kantian distinction of the pure and the empirical ego, the latter (“the Me known”) being an object of thought to the former (“the I knowing”).

From the use of the term “person” as distinguishing the Lateinisches etymologisches Wörterbuch (1906), suggests a derivation from Greek πρόσωπον, a zone. In Roman law persona was one who had civil rights. For the ecclesiastical persona ecclesiae, see Parson.

1 So Gabius Bassus in Gell. Noct. Att. v. 7, 1. Since, however, it is difficult to explain persona from personare (Skeat suggests by analogy from πρόσωπον the Greek equivalent), Walde, in
PERSONAL PROPERTY—PERSONATION

self from the not-self arises the phrase "personal equation" for those peculiar characteristics or idiosyncrasies which have to be taken into account in estimating the value of an individual judgment or observation. This phrase was used in astronomical observations of a Greenwich observer named Kinnebrook in 1705. The recognition fact that the greater or less inaccuracy is habitual to individual observers has been investigated, e.g. by Bessec (Abhandlungen, iii. 300) and by Wundt (Physiol. Psychol.), and machines have been devised which make allowance for the error caused by the personal equation (see Micrometer).

For the psychological problem, see Psychology. For the problems connected with sub-conscious action, &c., see Subliminal Self; Trance; Hypnotism; Telepathy.

PERSONAL PROPERTY, one branch of the main division of the English law of property, the other being "real property." The division of property into real and personal represents in a great measure the division into immovable and movable, except that the latter is not incidentally recognized in Roman law and generally adopted since. "Things personal," according to Blackstone, "are goods, money, and all other movables which may attend the owner's person wherever he thinks proper to go" (Comm. ii. 16). This identification of things personal with movables, though logical in theory, does not, as will be seen, perfectly express the English law, owing to the somewhat anomalous position of chattels real. In England real property is supposed to be superior in dignity to personal property, which was originally of little importance from a legal point of view. This view is the result of feudal ideas, and had no place in the Roman system, in which immovables and movables were dealt with as far as possible in the same manner, and descended according to the same rules. The main differences between real and personal property which still exist in England are these. (1) In real property there can be nothing more than limited ownership; there can be no estate properly so called in personal property, and it may be held in complete ownership. There is nothing corresponding to an estate-tail in personal property; words which in real property would create an estate-tail will give an absolute interest in personality. A life-interest may, however, be given in personally, except in articles quae tasto sunt consummatar. Limitations of personal property, equally with those of real property, fall within the rule against perpetuities. (2) Personal property is not subject to various incidents of real property, such as rent, dower or escheat. (3) On the death of the owner intestate real property descends to the heir; personal property is divided according to the Statute of Distributions. (4) Real property as a general rule must be transferred by deed; personal property does not need so solemn a mode of transfer. (5) Contracts relating to real property must be in writing by the Statute of Frauds, 21 Car. II. c. 3, s. 4; contracts relating to personal property need only be in writing when it is expressly so provided by statute, as, for instance, in the cases falling under s. 17 of the Statute of Frauds. (5) A will of lands need not be proved; but a will of personality or of personal and real property together must be proved in order to give a title to those claiming under it. (7) Devises of real estate fall as a rule within the Mortmain Acts (see Charity and Charities; Corporation) bequests of personal property, other than chattels real, are not within the act. (8) Mortgages of real property need not generally be registered; mortgages of personal property for the most part require registration under the Bills of Sale Acts (see Pledge, and Bill of Sale).

Personal estate is divided in English law into chattels real and chattels personal; the latter are again divided into choses in possession and choses in action (see Chattel; Chose).

Interest in personal property may be either absolute or qualified. The latter case is illustrated by animals ferae naturae, in which property is only coextensive with detention. Personal property may be acquired by occupancy (including the accessio, comminixio, and confusio of Roman law), by invention, as patent and copyright, or by transfer, either by the act of the law (as in bankruptcy, judgment and intestacy), or by the act of the party (as in gift, contract and will).

There are several cases in which, by statute or otherwise, property is taken out of the class of real or personal to which it seems naturally to belong. By the operation of the equitable doctrine of conversion money directed to be employed in the purchase of land, or land directed to be turned into money, is in general regarded as that species of property into which it is directed to be converted. An example of property prima facie real which is treated as personal is an estate pur autre vie, which, since 14 Geo. II. c. 20, s. 9, 1740-1741 (now replaced by the Wills Act 1837, s. 6) is distributable as personal property in the absence of a special occupant. Examples of property prima facie personal which is treated as real are fixtures, heirlooms, such as household and family plate, and shares in some of the older companies, as the New River Company, which are regarded by statute. In ordinary cases shares in companies are personal property, unless the shareholders have individually some interest in the land as land.

The terms heritable and movable of Scots law to a great extent correspond with the real and personal of English law. The main points of difference are these. (1) Leases are heritable as to the land, but not as to the habitation; the latter is movable. (2) Money due on mortgages and securities on land is personality in England. At common law in Scotland debuts secured on heritable property are themselves personal. (3) Bills of exchange are real property, but by the Bills of Exchange Act 1868, s. 117, heritable securities are movable as far as regards the succession of the creditor, unless executors are expressly excluded. They still, however, remain heritable quod ascending, as between husband and wife, &c. By a new provision (4) Annuities, as having tractum futuri temporis, are heritable, and an obligation to pay them falls upon the heir of the deceased (Watson, Law in Scotland, "Annuities").

The law in the United States agrees in most respects with that of England. Heirlooms are unknown, a unknown right to no right to an estate, except in the case of the property of freeholders. In some states estates pur autre vie descend like real property; in others an estate pur autre vie is deemed a fee simple only during the lifetime of the grantee; after his death it becomes a chattel real. In yet other cases the heir has a scintilla of interest as a special occupant (Kent, Comm. iv. 27). In some states railway-rolling-stock is considered as purely personal, in others it has been held to be a real estate, according to the nature of the machine, and in some of the early American corporations were, like New River shares in England, made real estate by statute, as in the case of the Cape Sable Company in Maryland (Schonler, Law of Personal Property, 256). In Louisiana slaves, except negroes and mulattoes, were regarded as immovables. In churches generally real property, but in some states they are made personal property by statute. The assignment of choses in action is generally permitted, and in most states regulated by statute. (J. W.)

PERSONATION, in English law, a form of fraud consisting in a false representation by one person (by words or conduct) that he is another person living or dead. It is not an offence by the common law unless the representation is made on oath under circumstances constituting the offence of perjury, or unless that representation if not made on oath is made under circumstances amounting to a common law cheat. Personation has been made an offence by statute in the following cases: (1) where it amounts to a false pretence by words or conduct, and is done with intent to defraud, and property is by such false pretence obtained, 24 & 25 Vict. c. 96 ss. 88-90 (see False Pretences); (2) in the case of false and deceitful personation of any person or of the heir, executor, administrator, widow, executor, administrator, or relator of such person with fraudulent intent to obtain any land, estate, chattel, money, valuable security or property (57 & 38 Vict. c. 36 s. 1); (3) in the case of personation of votes at elections (see Corruption of Practice).

The first of these offences is a misdemeanour only; the second is a felony punishable by penal servitude for life. The second offence was created in 1874 in consequence of the Tichborne case, in which under the law as it then stood it had been necessary
to prosecute the claimant for perjury. Besides the enactments above referred to there are also a number of provisions for dealing with the personation of sailors, soldiers, pensioners and owners of stock in the public funds or shares in joint-stock companies, and of persons who falsely acknowledge in the name of another recognizances, deeds or instruments before a court or person authorized to take the acknowledgment.

**PERSPECTIVE** (Lat. *perspicere*, to see through), in mathematics the name given to the art of representing solid objects by a plane drawing which affects the eye as does the object itself. In the article *Projection* it is shown that if all points in a figure be projected from a fixed centre to a plane, each point on the projection will be the projection of all points on the projecting ray. A complete representation by a single projection is therefore possible only when there is but one point to be projected on each ray. This is the case by projecting from one plane to another, but it is also the case if we project the visible parts of objects in nature; for every ray of light meeting the eye starts from that point in which the ray, if we follow its course from the eye backward, meets for the first time any object. Thus, if we project from a fixed centre the visible part of objects to a plane or other surface, then the outlines of the projection would give the same impression to the eye as the outlines of the things projected, provided that one eye only be used and that this be at the centre of projection. If at the same time the light emanating from the different points in the picture could be made to be of the same kind—that is, of the same colour and intensity and of the same kind of polarization—as that coming from the objects themselves, then the projection would give sensibly the same impression as the objects themselves. The art of obtaining this result constitutes a chief part of the technique of a painter, who includes the rules which guide him under the name of perspective, distinguishing between *linear* and *aerial* perspective—the former relating to the projection, to the *drawing* of the outlines, the latter to the colouring and the shading off of the colours in order to give the appearance of distance. Here we deal only with the former, which is in fact a branch of geometry consisting in the applications of the rules of projection.

§ 1. Our problem is the following: *There is given a figure in space, the plane of a picture, and a point as centre of projection; it is required to project the figure from the point to the plane.*

From what has been stated about projection (q.v.) in general it follows at once that the projection of a point is a point, that of a line a line. Further, the projection is in general a finite point. Hence parallel lines are projected into a pencil of lines meeting at some finite point. This point is called the *vanishing point of the direction* to which it belongs. To find it, we project the point at infinity in the parallel lines met at this point, we draw through the eye a line in the given direction. This cuts the picture plane in the point required.

Similarly all points at infinity in a plane are projected to a line (see *Projection*; § 6) which is called the *vanishing line of the plane* and which is common to all parallel planes.

*All lines parallel to the picture plane have their vanishing points at infinity in the picture plane; hence parallel lines which are parallel to the picture plane are projected as parallel lines in their true direction.*

The projection of a line is determined by the projection of two points in it, these being very often its vanishing point and its trace on the picture plane. A vanishing point is determined by the projection of two points through it.

These are the general rules which we now apply. We suppose the picture plane to be vertical.

*Fig. 1.*

in perspective is called the *point of sight, ABKL the picture plane, ABMN a horizontal line on which we suppose the objects to rest of which a perspective drawing is to be made. The lowest point in the picture is generally selected for this purpose, and is therefore called the ground plane, or sometimes the geometrical plane.

It cuts the picture plane in a horizontal line AB called the ground line or base line. A plane perpendicular to the picture plane, a horizontal line SV, drawn through the eye S perpendicular to the picture, cuts the latter at a point V called the centre of the picture or the centre of vision. The distance SV of the eye from the picture is often called the distance simply and the height ST of the eye above the ground the height of the eye.

The vanishing line of the ground plane, and hence of every horizontal plane, is got by drawing the projecting rays from S to the vanishing point of the plane—in other words, by drawing horizontal rays through S. These lie in a horizontal plane which cuts the picture plane in a horizontal line DD' through the centre of vision. This line is called the horizon in the picture. It contains the vanishing points of all horizontal lines, the centre of vision V being the vanishing point of all lines parallel to SV, that is perpendicular to the picture plane. To find the vanishing point of a horizontal line we draw the ray projecting the point at infinity in the line; that is, we draw through S a ray parallel to the line, and determine the point where this ray cuts the picture plane. If the line is given by its point on the ground plane, and its elevation on the picture plane, then its vanishing point can at once be determined; it is the vertical trace of a line parallel to it through the eye (cf. *Geometry*; § Descriptive, § 6).

§ 3. *To have construction in a single plane, we suppose the picture plane turned parallel to the ground plane; but before this is done the ground plane is pulled forward till, say, the line MN takes the place of the vanishing line and then the vanishing plane is turned. By this we keep the plan of the figure and the picture itself separate.* In this new position the plane of the picture will be that of the paper (fig. 2). On it are marked the base line AB, the centre of vision V, and the horizon DD' and also the limits of the actual picture. These, however, need not necessarily be marked. In the plan the picture plane must be supposed to pass through AB, and to be perpendicular to the ground plane. If we further suppose that the horizontal plane through the eye which cuts the picture plane in the horizon DD' be turned down about V, we find that the light will come to the point S, where VS equals the distance of the eye.

To find the vanishing point of any line in a horizontal plane, we have to draw through S a line in the given direction and see where it touches the horizon. In other words, to find the vanishing point of one of the two horizontal directions which make angles of 45° with the horizon, we draw through S lines SD and SD' making each an angle of 45° with the line DD'. These points can also be found by making VD and VD' each equal to the distance VS. The two points D, D' are therefore called the distance points.

§ 4. Let it now be required to find the perspective P of a point P (figs. 1 and 2) in the ground plane. We draw through P two lines of which the projection can easily be found. The most convenient lines are the perpendicular to the base line, and a line making an angle of 45° with the picture plane. These lines in the ground plane are KH and KH'. The first cuts the picture at Q or at K, or at both, and has the vanishing point Q or Q'. The other cuts the picture in R, or rather in R', and has the vanishing point D; its perspective is RD'. These two lines meet at P, which is the point required. The distance QR = Q'R' = Q'P gives the distance of the point P behind the picture plane. Hence if we know the point Q where a perpendicular from a point to the picture plane cuts the latter, and also the distance of the point P from the picture plane, we can find its perspective. We join Q to V, set off QR to the right equal to the distance of the point behind the picture plane, and join R to the distance point to the left; where KD cuts QV is the point P required. We set off Q'R' to the left equal to the distance and join R' to the distance point D' to the right.

If the distance of the point from the picture should be very great, the point R might fall at too great a distance from Q to be on the picture plane. In this case we might set off QW equal to the fourth part of the distance and join it to a point E, so that VE equals the fourth part of VD. Thus if QW = QR and VE = VD, then WE will again pass through P. It is thus possible to find for every point in the ground plane, or in fact in any horizontal plane, the perspective;
PERSPECTIVE

for the construction will not be altered if the ground plane be replaced by any other horizontal plane. We can in fact now find the perspective of every point as we know the perpendicular drawn from it to the picture plane, that is, if we know its elevation on the picture plane, and its distance behind it. For this reason it is often convenient to draw in slight outlines the elevation of the figure on the picture plane.

Instead of drawing the elevation of the figure we may also proceed as follows. Suppose (fig. 3) \(A\) to be the projection of the point of the picture plane above the ground plane, and \(A'\) the point directly below it. This process of drawing is the same as drawing in the perpendicular from the given point to the ground plane and measuring the length of these perpendiculars. If we then take the point \(A_1\), and erect at \(A_1\) a perpendicular in the picture plane to its base and set off on it \(A_2\), equal to the real height of the point \(A\) above the ground plane, then the point \(A_2\) is the point \(A_1\) in the picture plane.

If the shadow of a screen \(C\) falls on the floor, then \(C_1\) is the shadow of \(C\) in the picture plane. If the shadow of \(C_1\) falls on the floor, then \(C_1\) is the shadow of \(C\) in the picture plane. If the shadow of \(D\) falls on the floor, then \(D\) is the shadow of \(D_1\) in the picture plane. If the shadow of \(D_1\) falls on the floor, then \(D_1\) is the shadow of \(D\) in the picture plane. If the shadow of \(D_1\) falls on the floor, then \(D_1\) is the shadow of \(D\) in the picture plane.

§ 8. If the shadows are due to the sun, we have to find the perspective of the sun, that is, the vanishing point of its rays. This will always be in the picture plane; but we have to distinguish between the cases where the sun is in the front of the picture, and so behind the spectator, or behind the picture plane, and so in front of the spectator. In the second case only does the vanishing point of the rays of the sun actually represent the sun itself. It will be a point above the horizon. In the other case the vanishing point of the rays will lie below the horizon. It is the point where a ray of the sun through the centre of the picture plane, or it will be the shadow of the eye on the picture plane. We can find the ray of the sun through any point is the line joining the perspective of that point to the vanishing point of the sun's rays. But in the one case the shadow falls away from the vanishing point, in the other it falls towards it. The direction of the sun's rays may be given by the plan and elevation of one ray.

For the construction of the shadow of points it is convenient first to draw a perpendicular from the point to the ground and to find its shadow on the ground. But the shadows of verticals from a point at infinity will be parallel; hence they have in perspective a shadow point \(L_0\) in the horizon. To find this point, we draw that vertical plane which contains the eye and the point, and the horizon. This cuts the horizon in the required point \(L_0\) and the picture plane in a vertical line which contains the vanishing point of the sun's rays itself. Let then (fig. 4) \(L\) be the vanishing point of the sun's rays, \(L_1\) be that of their projection in a horizontal plane, and let it be required to find the shadow of the vertical column \(AH\). We draw \(AL\) and \(EL\); they meet at \(E\), which is the shadow of \(H\), and \(L_1E\) the required are drawn. Then \(EFGH'\) will be the shadow of the quadrilateral \(EFGH\). For the shadow of the column itself we join \(E\) to \(A\), &c., but only mark the outlines; \(FB\), the shadow of \(BF\), does not appear as such in the figure.

If the shadow \(E\) has been found when falling on any other surface we use the vertical plane through \(E\), determine its intersection with the surface, and find the point where this intersection is cut by the line of the shadow. This gives us the required shadow of \(E\).

§ 9. If the picture is not to be drawn on a vertical but on another plane—say, the ceiling of a room—the rules given have to be slightly modified. The general principles will remain true. But if the picture is to be on a curved surface the constructions become somewhat more complicated. In the most general case conceivable it would be necessary to have a representation in plan and elevation of the figure required and of the surface on which the projection has to be made. A number of points might also be found by calculation, using co-ordinate geometry. But into this we do not enter. As an example we take the case of a panorama, where the surface is a vertical cylinder of revolution, the eye being in the axis. The ray projecting a point \(A\) cuts the cylinder in two points on opposite sides of the eye, hence geometrically speaking every point has two projections; of these only the one lying on the half ray from the eye to the point can be used in the picture. But the other has sometimes to be used in constructions, as the projection of a line has to pass through both. Parallel lines have two vanishing points which are found by drawing a line of the given direction through the top of the cylinder in the vanishing points required.

This operation may be performed by drawing on the ground the plane of the ray through the foot of the axis, and through the point where it cuts the cylinder a vertical, on which the point required may be found by making a drawing of a vertical section on a reduced scale.

Parallel planes have in the same manner a vanishing curve. This will be for horizontal planes a horizontal circle of the height of the eye above the ground. For vertical planes it will be a circle of generators of the cylinder. For other planes the vanishing curves will be ellipses having their centre at the eye.

The projections of vertical lines will be vertical lines on the

---

**Fig. 3.**

---

**Fig. 4.**
cylinder. Of all other lines they will be ellipses with the centre at
and in, and if the cylinder be developed into a plane, then these ellipses will be changed into curves of sines. Parallel lines are thus represented by curves of sines which have two points in
common. There is no difficulty in making all the constructions on
the cylinder and the drawing board and then transferring them to
the cylinder.

§ 10. A variety of instruments have been proposed to facilitate
perspective, but the sole purpose of these is to make the drawing face
more true or, if a camera obscura or, better, Wollaston’s camera lucida
may be used. Other instruments are made for the construction of
perspective drawings. It will often happen that the vanishing point of some direction which would be very useful in the construc-
tion falls at a great distance off the paper, and various methods
have been proposed of drawing lines through such a point.

For some of these see Stanley’s Descriptive Treatise on Mathematical
Drawing Instruments.

PERSPIRATION (Lat. per, through, and spirare, to breathe),
the excretion of sweat from the sweat-glands of the skin. Sweat is a clear colourless neutral or slightly alkaline fluid containing 2% of solids. Under pathological conditions, sugar
urea and other substances are found. The secretion of sweat is
constantly going on, the activity of the sweat-glands being under
control of the central nervous system. The only function
of sweat is the regulation of the heat discharge from the
body. The chief morbid conditions of the sweat-glands are
excessive sweating (Hyperhidrosis) and footed sweating (Bromi-
drosis). Excessive sweating is a symptom observed in various
diseases, such as tuberculosis and rheumatic fever, but it may
exist apart from such conditions, and either be general, affecting
the whole body, or confined to a part, such as the axillae, head,
hands, feet, or, in some rare instances, the one half of the body.
Excessive perspiration may often be prevented by the cold bath,
and by tonics, such as iron, quinine, strychnia, &c. Locally,
from the use of astringents of vinegar or a weak solution of
lead will also be of service. Footed sweating most frequently
affects the feet, specially in those who have much fatigue,
and is apparently due to rapid decomposition in the perspiration
which has saturated the stockings; these should be frequently
changed and the feet washed several times a day, dried carefully,
and dusted with some antiseptic powder.

PERTAB (or PARTAB) SINGH, Sir, maharaja of Idar
(1844-1916), native Indian soldier and statesman, belonging to
the Rahtor Rajputs of the Jodha class, was born in 1844, being
the son of Maharaja Takhi Singh, ruler of Marwar (or Jodhpur).
In 1878 and again in 1879 he was chief minister of Jodhpur.
In the following year he accompanied the British mission to
Afghanistan, and on his return he carried out many judicious
reforms and administered Jodhpur with remarkable success. He
visited England to take part in the celebration of the 1887
Jubilee of Queen Victoria’s reign. He served on the staffs of
Sir William Lockhart and General Elles in the Tirah and Mofussil
expeditions in 1897-98, was slightly wounded, was mentioned
in despatches, and promoted to the rank of full colonel. He
won the reputation of being one of the keenest sportsmen and
the best riders that even Rajputana has produced. When it was decided to set up a force of 12,000 from India to China in
1900 to relieve the foreign embassies besieged in Peking, Sir
Partab Singh at once offered the services of the Jodhpur Lancers,
and himself accompanied them. His father rendered good
services to the British government in the Mutiny, and Partab
Singh always cherished the memory of the protection given to
Jodhpur by the East India Company in 1818. His services to
the empire in India were universally recognized. From
Queen Victoria he received the honour of knighthood and the Bath
and the Star of India; from King Edward VII the distinction
of ‘aide-de-camp’; and the university of Cambridge gave him
the degree of LL.D. From his own state of Jodhpur he
obtained the title of Maharaja-Drajam. In 1902 he succeeded
to the rulership of the state of Idar.

PERTH, EARLS AND DUKES OF. The Scottish title
of earl of Perth was bestowed upon James, 4th Lord Drummond
(d. 1671) in 1605. His ancestor Sir John Drummond (d. 1519)
had been created Lord Drummond in 1488. The 1st earl’s great
nephew, James, 4th earl and 1st duke of Perth (1648-1710),
was a son of James, the 3rd earl (c. 1615-1705). When John
Maitland, duke of Lauderdale, was virtually the dictator of
Scotland, Perth was among his opponents, and after Lauderdale’s
retirement in 1686 he was one of the committee of seven which
nominated the Scottish affairs. He was made justice-general and extra-
ordinary lord of session in 1682, and was the defender of
Scotland from 1684 to 1688. As a convert to Roman Catholi-
cism after the death of Charles II., he stood high in the favour of
James II. Perth, who is credited with the introduction of the
thimble-cure, was very unpopular with the Scottish people, and
during the Revolution of 1688 he was imprisoned at Stirling. Released
from captivity in 1693 he joined James II. at St Germain, and
was made duke of Perth, a titular dignity only after the exiled
king’s death in 1701. His son James (c. 1675-1720) was with
James II. in Ireland, and led the cavalry at the battle of Sheriff-
muir. He was attainted in 1715, but claimed the dukedom of
Perth after his father’s death. His son James (1713-1746),
regarded by friends and dependants as the 3rd duke of Perth,
fought for the Young Pretender at Prestonpans and Culloden.
His brother and heir, John, the 4th duke (c. 1716-1747),
also joined Charles Edward, and fought at Falkirk and Culloden.
The titular dukedom became extinct when the sixth holder,
Edward, another son of the 1st duke, died in 1760.

The earldom was then claimed by Edward’s cousin, James
Lundin (1707-1781), a grandson of the 1st titular duke of Melfort,
who was a brother of the 1st duke of Perth and took the name
of Drummond. His son James (1744-1800) secured the Drum-
mond estates in 1783, and was created a British peer as Lord
Perth and Baron Drummond in 1797. On his death without
sons in July 1800 his barony became extinct, but the claim
to the earldom of Perth was inherited by his kinsman, the 4th
titular duke of Melfort, and his descendants (see below).
The Drummond estates, however, passed to the baron’s daughter
Clementina (d. 1865), afterwards the wife of Peter Robert,
20th Lord Willoughby de Eresby, and thence to her descendant
the earl of Ancaster.

The 1st duke’s brother, John (c. 1650-1719), earl of Melfort,
rrose to favour under Charles II. about the same time as his
brother; like him, too, he became a Roman Catholic in 1686.
In 1684 he was made secretary of state for Scotland; in 1686 he
was created earl of Melfort by James II., and during his reign
he took a leading part in Scottish affairs. After the Revolution
of 1688 his great influence with James III. and with Mary of
Modena drew upon him the hatred both of the French and of
the Irish. He was with James II. at St Germain, but lost
his former ascendancy, and died in Paris on the 25th of January
1715. In 1694 he was made duke of Melfort, and all his titles
were held under the singular condition that they should descend
to the children of his second wife, Euphemia (d. 1743), daughter
of Sir Thomas Wallace, in preference to his children by his first
wife, Sophia Lundin, who were Protestants. In 1701 Melfort
was recognized as a French peer, theduc de Melfort,
by Louis XIV. In 1695 he had been attainted, but his titles were
claimed by John (1682-1779), his eldest son by his second
wife, who shared in the rising of 1715. In 1700 John’s grandson,
James Louis, 4th titular duke of Melfort, claimed the earldom
of Perth. This claim was unsuccessful, but in 1853 George
(1807-1902), nominally 6th duke of Melfort, obtained a reversal
of the various attendant, and his own recognition as earl of
Perth and Melfort. The succeeding earl was his kinsman,
William Huntly Drummond, Viscount Strathallan (1851-
). See Sir R. Douglas, The Peerage of Scotland; and Histories of Noble

PERTH, the capital of Western Australia, situated on the
Swan River, 12 m. by rail from the sea at Fremantle, and about
1700 m. S.N.W. of Melbourne. It is the seat of both Anglican
and Roman Catholic bishops, and has two cathedrals. The
fashionable street is St George’s Terrace; in it are situated the
public library, the government boys’ school, the stock exchange,
the town-hall, the government offices and the parliament build-
ings. Between it and the broad reach of the river known as
Perth Water lie the governor’s residence and domain. The
PERTH
town-hall, built entirely by convict labour, stands on an emi-
nent in the very heart of the city; opposite to it are the govern-
ment offices, housed in a four-storied structure in the style of
the French Renaissance. The mint, opened in 1809, is a massive
freestone building. There are a public library, built as a
memorial of Queen Victoria's Jubilee in 1887, a Scots college,
two hall, a 'Mechanics' institute, a museum, and a
fine Wesleyan church-house, known as Queen's Hall. The
Perth Park, containing about 1200 acres, is connected by tram
with the city, and in it is a well-equipped observatory.
There are several smaller parks and squares in the city, while the
esplanade gardens are a feature of the place, being thrown out
like a pier into Perth Water. There is a good cricket ground,
and three race-courses are in easy reach. South Perth, on the
other side of the river, is connected by bridges and steam ferry;
and adjoining the city on the north-west are the suburban
municipalities of Leederville and Subiaco. Outlying suburbs
are Belmont, Victoria Park, Burswood, Claremont, Cottesloe,
Peppermint Grove and Bayswater. The city is lighted by
electricity, and has a good service of electric trams. Perth
has an agreeable climate, the mean temperature is 64° F.,
and the average rainfall 33 in. Perth was founded in 1829,
received its municipal charter in 1856, and was created a city
in 1880. Between 1891 and 1901 the growth of the city was
remarkably rapid; in 1891 the population was only 8447, but
in 1901 it had grown to 27,471 in the city proper, and to 36,199
including the suburbs.

PERTH, a city, and royal, municipal and police burgh, and
county town of Perthshire, Scotland, 32 m. N. by W. of Edin-
burgh direct, and 47½ m. by the North British railway, via
the Forth Bridge and Kinross Junction. Pop. (1901), 33,566.
It is situated on the right bank of the Tay, between the meadows
of the North Inch (98 acres) and those of the South Inch (72
acres), both laid out as public parks. The river is crossed by
St John's Bridge of nine arches, completed in 1772 from the
designs of John Smeaton and widened a century later; by Victoria
Bridge, a modern structure connecting South Street with Dundee
Road; and further south (at the end of Tay Street) by a footway
alongside of the viaduct belonging to the Caledonian railway.
Of earlier bridges one, which crossed at High Street, was swept
away by the flood of 1821, and another, constructed by General
Wade in 1722-1723, has apparently the predecessor of Smeaton's
bridge. On the left bank of the river lie the suburb of Bridgend
and Kinnoull Hill (720 ft.). To the south are the wood-clad
heights of Moncrieffe Hill (725 ft.), Magdalenes Hill (596 ft.),
Kirkton Hill (540 ft.) and Craigie Wood (407 ft.). In the river are
Friarton or Moncrieffe Island and the Stanners.

Notwithstanding the importance of Perth in former times,
almost the sole relic of the past is the church of St John the
Baptist, a large Decorated cruciform building surmounted by
a massive square central tower 155 ft. high. The original edifice
is believed to have been erected in the time of Columba, but the
transept and nave of the existing structure date from the early
part of the 13th century, the choir from the 13th. The church
was restored in 1801, and is now divided into the East, Middle
and West churches. The silver-gilt communion cup used in the
Middle Church is said to have been presented by Queen Mary.
In May 1559 John Knox preached in St John's his famous sermon
in denunciation of idolatry. The Dominican or Blackfriars'
omastery, founded by Alexander II. in 1231, occupied a site
near the west end of St John's Bridge; in what is now King
Street stood the Cuthianus monastery, founded by James I.
1425, the Franciscan or Greyfriars' monastery, founded in
1460 by Laurence, first Lord Oliphant, stood on the present
Grosvenor Street. The Carmelite's monastery, founded in
1260, stood west of the town. The tombstone of
James I. and his queen, who were buried in the Charterhouse,
was afterwards removed to St John's East Church. During the
period between the beginning of the 12th century and the
assassination of James I. in 1437, many of the Scottish parlia-
ments were held in Perth. The building in which they met
stood off High Street and was only cleared away in 1818, its
site being occupied by the Freemasons' Hall. The Earl of
Gowrie's palace, built in 1520, stood in spacious grounds near
the river and was removed in 1805 to provide room for the
county buildings. The castle of Perth stood on the north of High
Street, not far from St John's. It was probably built about
1260 and demolished about 1400. The Spey or Spy tower, the
most important fortress on the city wall, guarded the south gate
close to the river, but it was taken down early in the 19th century.
The market cross, erected in High Street in 1669 to replace
the older cross which Cromwell destroyed, was removed in
1765 as an obstruction. The huge fortress, 466 ft. square, which
Cromwell erected in 1651 on the South Inch, close to the river
and the Greyfriars' burying-ground, was demolished in 1663.
The house of Catherine Glover, the "Fair Maid of Perth," still
stands in Curlewe Row. James V.'s Hospital, founded in 1569,
occupies the site of the Carthusian monastery, the original
structure having been pulled down by Cromwell's orders. The
pensioners now live out and the hospital has been converted
into artisans' dwellings. Among modern public buildings the
principal are St Ninian's Episcopal Cathedral, in the Early
Middle Pointed style, an important example (completed 1850)
of the work of William Butterfield (1814-1900); the municipal
buildings (1881); the city-hall; the Marshall Memorial Hall
(1823), housing the public library and the museum of the
Perth Literary and Antiquarian Society; the Perthshire natural
history museum; the Sandeman public library (1860), founded by
a bequest of Professor Sandeman of Owens College, Manchester.
The general prison for Scotland, south of the South Inch, was
originally erected in 1812 as a depot for French prisoners, but
was remodelled as a convict prison in 1840 and afterwards enlarged.
North-west of the city are the military barracks built in 1793-
1794. Besides the regular elementary schools there are the
Perth Academy (1807) with which was subsequently amalgamated
the Burgh Grammar School, an institution supposed to date from
the 12th century; Sharp's institute (1860); the Stewart's
free school, an industrial school for girls, and the Fechny
industrial school. The charitable institutions comprise the
royal infirmary, in the Italian style, considerably enlarged
since its foundation in 1836; the Murray royal lunatic asylum
in Bridgend; the Hillside House in Kinnoull and the small-pox
hospital.

From the south the city is entered by the North British
railway and the Caledonian railway (which also runs west to
St Fillans, east to Dundee and north-west to Aberdeen);
and from the north by the Highland railway, the three
systems utilizing a general station in the south-west of
the town. During the season there is communication with
Dundee and other river ports by steamer. The navigation of
the stream is considerably obstructed by sandbanks, but
vessels of 200 tons can unload at the quays, which, with
the town and Friarton harbours, lie below the South Inch.
The greatest tidal rise is 13 ft. The chief imports are Baltic timber,
coal, salt and manure; and the exports, manufactured goods,
grain, potatoes and slates. Perth has long been famous for its
dying and bleaching, the bleach-fields being mostly situated
outside of the city, in convenient proximity to the Tay and
Almond. The other leading industries include manufacturers of
gauge-glasses, ink, muslins, India shawls, jute goods, woollens
and wineces, floorcloth, and boots and shoes. There are iron
foundries, breweries, distilleries, rope and sail works, coach-
building yards, steam joinery works, and brick and tile works.
The salmon fisheries of the Tay yield a substantial revenue.
Perth is under the jurisdiction of a town council, with a lord
provost and bailies, and returns one member to parliament.

History—During the 13th century, the town was
reckoned to contain 1571 houses, and at the Reformation
a population estimated at 320 years, the city was called
Victoria; but shortly after their withdrawal it seems to have
borne the Celtic appellation of Aber-tha ("at the mouth of the
Tay"). The transition to the latinized form Bertha and later to
Perth (the Gaelic name being Pearn) appears obvious.
On the conversion of the original Pictish inhabitants and the
dedication of the first church to St John the Baptist, the town
was designated St Johnstown, and it continued to be known indifferently by this name and that of Perth down to the 17th century. Roman remains have been often found in excavations carried out within the existing boundaries, which suggests that the Roman settlement was at least twenty feet below the present surface. The obscurity of the early annals of the town is explained by the circumstance that Edward I. caused the records to be removed. Perth is stated to have been a burgh in 1106 and was made a royal burgh by William the Lion in 1210. During the Scottish wars of the Independence its fortifications were strengthened by Edward I. (1298). Robert Bruce several times ineffectually attempted to seize it, but in 1311 he succeeded in scaling the walls during a night attack. This was the fourth and most brilliant of the seven sieges which the city has sustained. Taken by Edward III. in 1335; it was recaptured in 1339. In 1346 the combat between the Clan Chattan and the Clan Quhile, described in Scott's Fair Maid of Perth, took place on the North Inch in presence of Robert III. and his queen, Annabella Drummond. The Blackfriars' monastery was the scene of the murder of James I. by Walter, earl of Atholl, in 1437. In consequence Perth lost its status as capital, in which it had succeeded to Scone, and the Parliament Courts were transferred to Edinburgh in 1482. Govie Palace was the scene of the mysterious "Gowrie" conspiracy against James VI. in 1600. The town was taken by Montrose in 1644, by Cromwell in 1651, and was occupied by Viscount Dundee in 1689. In 1715 the Old Pretender was proclaimed king at the Mercat Cross (Sept. 16), and the chevalier himself appeared in the city in the following January, only to leave it precipitately on the approach of the earl of Argyll. Prince Charles Edward spent a few days in Perth from the 3rd of September 1745. In both rebellions the magistrates took the side of the Crown and were supported by the townsfolk generally, the Jacobites drawing their strength mainly from the county noblemen and gentry with their retainers. Since then the city has devoted itself to the pursuits of trade and commerce. Perth was visited by plague in 1512, 1555–1557, 1668 and 1645; by cholera in 1832; and the floods of 1210, 1621, 1740, 1773 and 1814 were exceptionally severe.

AUTHORITIES.—Maidment, The Chronicle of Perths from 1270 to 1688 (1831); Penney, Traditions of Perth (1858); Laws of the Thistle of Perth (1847); Peacock, Perth, its Annals and Archives (1849); Samuel Coven, The Ancient Capital of Scotland (1904).

PERTH AMBOY, a city and port of entry of Middlesex county, New Jersey, U.S.A., at the mouth of the Raritan river, on Raritan Bay and Staten Island Sound, about 15 m. S. by W. of Newark. Pop. (1910 census) 32,121. It is served by the Pennsylvania, Lehigh Valley, Central of New Jersey and Staten Island Rapid Transit railways, and by boats to New York City. It is connected by a railway bridge (C.R.R. of N.J.) and by a foot and wagon bridge with South Amboy, on the south shore of the Raritan. Perth Amboy has a good harbour, shipyards and dry-docks. In the city still stands Franklin Palace (erected in 1762–1774), the home of William Franklin (1729–1813), a natural son of Benjamin Franklin and the last royal governor of New Jersey. In the vicinity is the Bartow House, in which William Dunlap (1766–1839), the art historian, made his first drawings. Other buildings of historic interest are the Parker Castle (c. 1729), a centre of Loyalist influence at the time of the War of Independence, and the Kearny Cottage, the home of "Madam Schriberius," a half-sister of Captain James Lawrence. The city has various manufactories, the factory product in 1905 being valued at $34,800,402. Clay is obtained in the vicinity, and large shipments of coal are made. Perth Amboy was founded in 1683. It was at first called Amboy after the original Indian name; in 1684 the proprietors named it Perth in honour of James, earl of Perth (1648–1716), one of their number, and a few years later the two names were combined. From 1686 until the end of the proprietary government in 1702 Perth Amboy was the capital of the province of the state of East Jersey, and during the period of royal government the general assembly and supreme court of New Jersey met alternately here and at Burlington. Perth Amboy was incorporated as a city in 1718, and received a new charter in 1784, and another in 1844, the last being revised in 1870. The township of Perth Amboy was incorporated in 1693 and in 1734 was included in Monmouth County. In 1734 a number of emigrant Roman Catholic authors. Perthes was an ardent patriot; and during the period of Napoleon's supremacy he distinguished himself by his steady resistance to French pretensions. His zeal for the national cause led him, in 1801–1811, to issue Das deutsche Museum, to which many of the foremost publicists in Germany contributed. For some time the French made it impossible for him to live in Hamburg; and when, in 1814, he returned to that city he found that his business had greatly diminished. In 1821, his wife having died, he left Hamburg, transferring his business there to his partner, and went to Gotha, where he established what ultimately became one of the first publishing houses in Germany. It was owing to his initiative that the Börseverband der deutschen Buchhändler (Union of German Booksellers) in Leipzig was founded in 1825. When the foundation-stone of the fine building of the Union was laid in 1834, Perthes was made an honorary freeman of the city of Leipzig, and in 1840 the university of Kiel conferred upon him the degree of doctor of philosophy. Perthes died at Gotha on the 18th of May 1843. His Life was written by his son, Klemens Theodor Perthes (1809–1867), professor of law in the university of Bonn, and author of Das deutsche Staatsleben vor der Revolution (Hamburg and Gotha, 1845), and Das Herbergewesen der Hansestädte (Gotha, 1858, and again 1885), whose son, Hermann, founded the journals and under the firm of the Freidricianaum at Davos Platz. The publishing business at Gotha was carried on by Perthes's younger son, Andreas, (1813–1890) and his grandson, Emil (1841–1912), until 1880, when it was handed over to a company.

See also O. Adler, Friedrich and Karoline Perthes (Leipzig, 1900).

PERTHES, JOHAN GEORG JUSTUS (1749–1810), German publisher, was born at Rudolstadt on the 11th of September 1749. In 1785 he founded at Gotha the business which bears his name (Justus Perthes). In this he was joined in 1814 by his son Wilhelm (1793–1853), who had been in the establishment of Justus' nephew, Friedrich Christoph Perthes, at Hamburg. On the death of Justus at Gotha on the 13th of May 1816, Wilhelm took entire control of the firm. He laid the foundation of the geographical branch of the business, for which he is chiefly famous, by publishing the Hand-atlas (1817–1822) of Adolf Stieler (1775–1836). Wilhelm Perthes engaged the collaboration of the most eminent German geographers of the time, including Heinrich Berghaus, Christian Gottlieb Reichard (1738–1837), who was associated with Stieler in the compilation of the atlas, Karl Spruner (1803–1829) and Emil von Sydow (1812–1873). The business passed to his son Bernard Wilhelm Perthes (1820–1884), who was associated with August Petermann (under whose direction the well-known periodical Petermanns Mitteilungen was founded) and Bruno Hassenstein (1836–1902); and subsequently to his son Bernard (1837–1928). In 1863 the firm first issued the Almanach von Gotha, a statistical, historical and genealogical annual (in French) of the various countries of the
PERTHSHIRE, an inland county of Scotland, bounded N. by the shires of Inverness and Aberdeenshire, E. by Forfarshire; S.E. by the Firth of Tay and the counties of Fife and Kinross; S. by the shires of Clackmannan and Stirling; S.W. by the counties of Stirling and Dunbarton; W. by Argyleshire and N.W. by Inverness-shire. It is the fourth largest county in Scotland, having an area of 1,595,774 acres, or 2403.4 sq. m., including the island of Mudgean in the Firth of Tay. By far the greatest part of the county is mountains. Including the hills on the confines of Inverness-shire and Argyleshire, there are at least fifty mountains exceeding 3000 ft. in height. Of these the most familiar are Ben Lui (3848 ft.) near Loch Tay, Ben More (3543) east of Crinanhill, Ben Lui (3708) on the Argyllshire border, Schiehallion (3547) south of Loch Rannoch, Ben Vannoch (3125) west of Loch Lyon, and Ben Conchie (3048) near the head of Glen Almond. Of the immense number of hills of lesser altitude there may be mentioned four that have been popularized by the Lady of the Lake—Ben Ledi (2875) and Uam Var (2170) near Callander, and Ben Venue (2303) and Ben A'an (1750), guardians of the Trossachs. The Ochils divide Perthshire from the shires of Clackmannan, Kinross and Fife. The chief stream is the Tay, which rises on the Argyllshire frontier and discharges into the North Sea off Buddon Ness, after a course of 117 m., being thus the longest river in Scotland. Its head-waters are the Fillan and Dochart, and among its affluents are, on the right, the Braan, Almond and Earn and, on the left, the Lyon, Tummel, rising in Argyllshire and receiving the Garry on its left, and Isla. The Earn flows out of Loch Earn and enters the Firth of Tay 63 m. below Perth. The Firth, the principal natural boundary of the shore on the south, properly belongs to Stirlingshire, in which it rises, but its leading left-hand affluents are Perthshire rivers, namely, the Teith, the Goodie, issuing from the lake of Menteith, and the Allan, rising in the Ochils near Sherrifmuir. All the lakes are narrow, scarcely one exceeding a mile in width. Loch Ericht, belonging partly to Inverness-shire, is 14½ m. long. Loch Tay (14 m. long), situated about the centre, is the largest lake in the county. In the south are the series of lakes which the Lady of the Lake has described as the "Lake District," viz., Lochs Achray (14 m. long), Loch Katrine (about 8 m. long), and the west of Aberfoyle is Loch Ard (3 m. long) and to the east Lake Menteith (1½ m. long). Nearly all the glens possess striking natural features, among them, from south to north, being Glens Artney, Almond, Dochart, Ogil, Lochay, Lyon, Garry, Shee, Braar and Tilt; while the Trossachs, Killiecrankie, Birnam and Leny are the loveliest passes in the Highlands. The low-lying country is represented mainly by Strathmore, Strath Gartney, Strath- allan, noted for its annual "gathering" or games, Strathearn, Strath Bran, Strath Tay and Strath Fillan, but more particularly by the fertile alluvial belts of the Carse of Gowrie, on the northern side of the Firth of Tay, and the Carse of Stirling. The Moor of Rannoch on the borders of Argyllshire is a great boulder-strewn waste, and Flanders Moss, to the south-east of Lake Menteith, is a vast boggy tract, which is, however, being gradually reclaimed and brought under cultivation.

Geology.—The Highland portion of this county is built up of a great series of schists and metamorphosed rocks grouped as "Dalradian," or "Eastern High Group." The general direction of the strike of these rocks is from N.W. to S.E. N. of the head of the Red Sandstone, which occupies most of the remainder of the county, by the great fault which traverses the country somewhat to the north of the line of the Tay. To the west of this fault there is some distance north and east of Crieff the boundary between these two formations is very unconformable one. In the neighbourhood of the Highland the Red sandstones are less metamorphosed than they are farther north, and are comprised of greywacke, grits, porphyrites, micaceous and gneissic rocks with radiolarian cherts and black shales. Long persistent, the argillaceous and granitic rocks of the Arenig age in south Scotland. At Aberfoyle, Comrie and Dunkeld roofed rocks are worked and massive limestones occur in Glen Tilt, Pitlochry, Callander, Blair Atholl, Loch Rannoch and other places. A gritty series occurs on above the

PERTHSHIRE; world; and in 1866 the elaborate Geographisches Jahrbuch was produced under the editorship of Ernst Behm (1830-1884), on whose death it was continued under that of Professor Hermann Wagner.
direction via Perth. At Crieff station it sends off a branch to Crieff and at Perth branches to Dundee and Lochee head. The stirling-by-pass line of the same company crosses the shire from Dunblane to Tyndrum. The Highland railway runs northwards from Perth, and has a branch at Ballinluig to Aberfeldy. Branches of the North British railway reach Perth from Mawcar, Stirlingshire and Ladybank in Fife; part of the branch from Buchlyvie on the Forth and Clyde line runs to Aberfoyle, and the West Highland railway skirts the extreme west of the shire. At several points railways supplement the rail. In the tourist season, accommodation is available on Loch Tay and Loch Katrine, and there is a service on the Tay between Perth and Dundee.

Population and Administration.—In 1891 the population amounted to 122,125 and in 1901 to 123,283, or 49 persons to the sq. m. The rate of increase was the smallest of any Scottish county for the decade. In 1901 there were 78 persons speaking Gaelic only and 11,446 Gaelic and English. The chief towns are Perth (pop. 32,873), Crieff (2508), Blairgowrie (3278), Dunblane (2576), Auchterarder (2576), Coupar Angus (2664), Rattray (1970). Among lesser centres may be mentioned Aberfeldy (1968), a favourite resort on the Tay, well known for the falls of Moness, mentioned in Robert Burns’s song “The Birks of Aberfeldy”; Abernethy (623), the seat of an early bishopric, retaining one of the three ancient round towers in Scotland; Alyth (1963); Callander (1458); Comrie (1118), a holiday resort on the Earn; Pitlochry (1541); and Stanley (1035), on the Tay. Of old the county was divided into hereditary jurisdictions, which were abolished in 1748, and in 1795 the county was divided into districts for administrative purposes, a system which obtained until 1889, when county and district councils were established. The sheriffdom is divided into an eastern and western district, the seat of the one being Perth and the other Dunblane. For parliamentary purposes the county is also divided into an eastern and a western division, and the city of Perth returns a member. The shire is under school-board jurisdiction, and there are secondary schools at Perth and Crieff, and Trinity College in Glen Almond is a well-known public school on the English model.

History.—In 83 Agricola explored the lands beyond the Forth and in the following year penetrated to the Grampians, defeating the Caledonians under Galgacus with great slaughter. The site of this battle is conjectured by William Forbes Skene to have been near Meikleour, south of Blairgowrie, but other writers have ventured to it to Dalginross, near Comrie, to Ardch, where there are the most perfect remains of a Roman encampment in the British Isles; and even as far north as Raedykes, near Stonehaven in Kincardineshire. The Romans did not pursue their victory, and the Picts were left undisturbed for a considerable period. At this time, according to Ptolemy, the territory now known as Perthshire was occupied by three tribes—the Damnonii, the Veneciones and the Vacamagi. The Damnonii held Menteith, Strathearn and Fothri (the western part of modern Fife and Kinross), with Alana (Allan), just above Stirling, Lindum (Ardoch) and Victoria (believed by some authorities to be Lochore in Fifeshire, and by others to be Perth city), as their chief towns. The Veneciones inhabited north-western Fife and the adjoining tract of Perthshire, with Orren (probably Abernethy) as their chief town and a station at Ardrioke. The Vacamagi dwelt in the Highland region, with stations at Inch-tuthill (a peninsula in the Tay above Kinclaven) and Banatia (Buchanay on the Almond). The growing lawlessness of the southern Picts and their frequent raids in the more settled country in the south at last compelled the attention of the emperor Severus. He arrived in Britain in 208, but though he led a strong army to the shores of the Moray Firth, he was unable effectually to subdue the tribesmen. The road he constructed ran from Stirling to Ardoch (where there are notable remains) and thence by Stragenach, near Muthill, where it branched north-westwards to Dalginross and Buchanay, and north-eastwards to Ardoch and so to Forfar, where the Romans finally withdrew from Britain, the Picts established their capital first at Abernethy and then at Forteviot. Abernethy was the centre of the Celtic church after the conversion of the natives by Ninian, Palladius and other missionaries in the 6th and 7th centuries. On the burning of Forteviot by the Norsemen in the 8th century, the seat of Pictish government was removed to Scone. In the latter half of the 9th century Dunkeld—to which Kenneth Macalpine had brought some of the relics of Columba from Iona—became the scene of monastic activity, the abbots succeeding to the position of the abbot of Iona, and exercising great influence for nearly a hundred years. The Danes periodically harried the land, but a crushing defeat at Luncarty in 961 put an end to their inroads in this quarter. In 1054 Macbeth was defeated at Dunnsanine by Siward, earl of Northumberland, who had invaded Scotland in the interest of his kinsman, Duncan’s son, who, on the death of the usurper three years later, ascended the throne as Malcolm III., called Canmore. With Malcolm’s accession the Celtic rule of the monarchy of Scone came to an end. Nevertheless, the Scottish sovereigns (excepting James II., James III. and Mary) continued to be crowned at Scone, which also retained the position of capital until the beginning of the 12th century, when it was displaced by Perth. From the time of Alexander I. (d. 1124), therefore, the history of the shire is merged in that of the county town, with the exception of such isolated incidents as the removal of the Coronation Stone from Scone to Westminster in 1206, the defeat of Robert Bruce at Methven in 1306, the battle of Dupplin in 1332, the victory of Dundee at Killiecrankie in 1689 and the indecisive contest at Sheriffmuir in 1715. Among archaeological remains may be mentioned the hill-fort on Dunnsanine; the ship-barrow of the Vikings at Rattray, weems (or earth-houses) in the parishes of Monzie, Alyth and Bendside; the witch-stone near Cairnbeddie, one of the numerous spots marked by these magical stones, and a probable sepulchral memorial of some forgotten battle; standing stones near Pitlochry, and an extraordinary assemblage of sculptured stones at Meigle.

Cunningham-Grant, Meikleoch on the District of Menteith (London, 1895); Hutchinson, The Lake of Menteith (Stirling, 1899).

PERTINAX, PUBLIUS HELVIUS (A.D. 126-155), Roman emperor, the son of a charcoal-burner, was born at Alba Pompeia in Liguria. From being a teacher of grammar he rose through many imperial offices, both civil and military, to the consulate, which he held twice. Chosen, at an advanced age and against his will, on the 1st of January 132, to succeed Commodus, he was himself assassinated in a mutiny of the soldiers, on the 28th of March 193.

PERTZ, GEORG HEINRICH (1755-1786), German historian, was born at Hanover on the 28th of March 1755. From 1783 to 1788 he studied at Göttingen, chiefly under A. H. L. Heeren. His graduation thesis, published in 1789, on the history of the Merovingian mayors of the palace, attracted the attention of Baron Stein, by whom he was engaged in 1790 to edit the Carolingian chronicles for the newly-founded Historical Society of Germany. In search of materials for this purpose, Pertz made a prolonged tour through Germany and Italy, and on his return in 1823 he received at the instance of Stein the principal charge of the publication of Monumenta germaniae historicà, texts of all the more important historical writers on German affairs down to the year 1500, as well as of laws, imperial and regal archives, and other valuable documents, such as letters, falling within this period. Pertz made frequent journeys of exploration to the leading libraries and public record offices of Europe, publishing notes on the results of his explorations in the Archiv der Gesellschaft d. deutschen Geschichtskunde (1824-1827). In 1825 he had been made secretary of the archives, and in 1827 principal keeper of the royal library at Hanover; from 1832 to 1857 he edited the Hannoversche Zeitung, and in 1842 he was appointed travelling secretary of the Hanoverian second chamber. In 1842 he was called as chief librarian to Berlin, where he shortly afterwards was made a privy councillor and a member of the Academy of Sciences. He resigned all his appointments in
1874, and on the 7th of October 1876 died at Munich while attending the sittings of the historical commission.

The *Monumenta* began to appear in 1826, and at the date of his resignation 24 volumes folio (Scriptores, Leges, Diplomata) had appeared. This work for the first time made possible the existence of the modern school of scientific historians of medieval Germany. In connexion with the *Monumenta* Peritz also began the publication of a selection of sources in octavo form, the *Scriptores rerum germanicarum in usum scholaram*; among his other literary labours may be mentioned an edition of the Gesammelte Werke of Leibnitz, and a life of Stein (Loben des Ministers Prechters von Steinfel (6 vols., 1849-1855); also, in an abridged form, *Aus Steins Leben* (2 vols., 1856).

**PERU**

![Map of Peru](https://example.com/map)

**PERU** (apparently from Biru, a small river on the west coast of Colombia, where Pizarro landed), a republic of the Pacific coast of South America, extending in a general N.N.W.-S.S.E. direction from lat. 3° 21' S. to about 18° S., with a sea-coast of 1240 m. and a width of 300 to 400 m., exclusive of territories in dispute. Its area in 1906, including Tacna and Arica, and other disputed territories occupied by neighbouring states, was officially estimated at 1,752,442 sq. kilometers, or 676,638 sq. m.; exclusive of these territories, the area of Peru is variously estimated at 439,000 to 480,000 sq. m., the Gotha measurements being 1,137,000 sq. kilometers, or 439,014 sq. m.

With the exception of parts of the Ecuador, Brazil and Bolivia frontiers, all the boundary lines have been disputed and referred to arbitration—those with Colombia and Ecuador to the king of Spain, and that with Bolivia to the president of Argentina, on which a decision was rendered on the 9th of July 1879. There have been misunderstandings with Ecuador in regard to some small areas in the Chira valley, but it may be assumed that the line is fixed between Santa Rosa (5° 21' S.) on the Gulf of Guayaquil, and the Chinchepe river, a tributary of the Marañon. At the junction of the Cauches with that river, that Ecuadorian line descends the Chinchepe to the Marañon, and the Peruvian ascends to a point where it is intersected by a line following the eastern Cordillera northward to the head-waters of the Casquetá, or Japura, which forms the northern boundary down to the Brazilian frontier. This claim covers all eastern Ecuador and a large part of south-eastern Colombia. In 1903 there were encounters between small bodies of Peruvian and Ecuadorian troops on the disputed frontier. After arbitration by the king of Spain had been agreed upon, the question was considered by two Spanish commissions, and modifications favouring Peru were recommended. These became known prematurely, and in May 1910 war was threatened between Peru and Ecuador in spite of an offer of mediation by the United States, Brazil and Argentina under the Hague Convention.

From the Japura southward to the Amazon, in 4° 13' 21" S., 69° 35' W., and thence up the Javy or Yavari to its source in 7° 8' 4" S., 73° 46' 36" W., as determined by a mixed commission, the line has been definitely settled. From near the source of the Javy, or lat. 7° 1' 17" S., a line running eastward to the Madeira in lat. 6° 52' 15" S., which is half the distance between the mouth of the Mamoré and the mouth of the Madeira, divides the Spanish and Portuguese possessions in this part of South America, according to the provisions of the treaty of San Ildefonso of 1777. This line has been twice modified by treaties between Bolivia and Brazil, but without the consent of Peru, which claimed all the territory eastward to the Madeira between the above-mentioned line and the Beni-Madidi rivers, the line of demarcation facing the Pablo-bamba, a small tributary of the Madidi, to its source, and thence in a straight line to the village of Conima, on Lake Titicaca. The dispute with Brazil relates to the territory acquired by that republic from Bolivia in 1867 and 1903, and was to be settled, according to an agreement...
of 1908, by direct negotiation if possible, or, failing this, by arbitration. The decision of the president of Argentina of the 9th of July 1909, in regard to the remainder of this extensive territory, was a compromise, and divided it into two nearly equal parts. The line adopted starts from Lake Suches, the source of a small river of that name flowing into the north of Lake Titicaca, crosses the Cordillera by the Palomoma to the Titicaca. From the latter follows that stream, thence into Ecuador, to the coast to the south. On the sand and beach the coast-line, of an anastomosing and confused nature, thence across to the source of the Heath river, which forms the dividing line down to its junction with the Madre de Dios, descends that river to the mouth of the Turosmonas, thence in a straight line north-westwards to the intersection of the Tahuamanu river by the 60th meridian, and thence north on that meridian to the Brazilian frontier. This decision at first gave offence to the Bolivians, but friendly overtures from Peru led to its acceptance by both parties with the understanding that modifications would be made in locating the line wherever actual settlements had been made by either party on territory awarded to the other. With Chile the de facto line is that of the Camarones ravine which separated the old department of Moquegua, including the provinces of Tacna and Arica, from that of Tarapacá. The de facto line is that of the Sama river (usually dry), which opens on the coast a little south of Sama point, near 18° S., Chile retaining possession of the two above-mentioned provinces in violation of the treaty of Ancon, which she forced upon her defeated antagonist.

**Physical Geography.**—Peru is divided longitudinally into three well-defined regions, the coast, the sierra and the montaña. The coast, extending from the base of the Western or Maritime Cordillera to the Pacific Ocean, consists of a sandy desert crossed at intervals by rivers flowing through narrow, fertile valleys. The sierra is the region of the Andes, and is about 250 m. in width. It contains stunted and impoverished remnants of the Central American table-lands, warm and fertile valleys and ravines. The montaña is the region of tropical forests within the valley of the Amazon, and skirts the eastern slopes of the Andes.

The desert of Peru is the ocean at no very distant geological epoch, and is nearly as destitute of vegetation as the African Sahara. It is watered, however, by fifty streams which cross the desert at intervals. Half of these have their origin in the summits of the Andes, and run with a permanent supply of water into the ocean. The others, rising in the outer range, which does not reach the snow-line and receives less moisture, carry a volume of water to the sea during the rainy season. The absence of rain here is ascribed to the action of the lofty uplands of the Andes on the trade-wind, and to the influence of the cold Humboldt current at the coast of Peru and the cold currents of the South Atlantic.

The south-east trade-wind blows obliquely across the Atlantic Ocean until it reaches Brazil. By this time it is heavily laden with vapour, which it continues to bear along across the continent, and to deposit upon the coast and in the valleys formed by the rivers of Peru, La Plata. When the wind rises above the snow-capped Andes, the last particle of moisture is wrung from it that a very low temperature can extract. Passing the summit of that range, it rushes down as a cool and dry wind on the Pacific slopes beyond. Meeting with no evaporating surface, and with no temperature colder than that to which it is subjected on the mountain-tops, this wind reaches the ocean before it becomes charged with fresh moisture. The constantly prevailing wind on the Peruvian coast is from the south, which is a cold wind from the Humboldt current. As it moves north it becomes gradually warmed and takes up moisture instead of depositing it as rain. From November to April it extends its influence, and the constant wind is an almost insensible, though by no means oppressive, heat. From June to September the sky is obscured for weeks together by fog, which is often accompanied by drizzling rain called _lluvia_, which when it is hottest and driest often continues raining heavily in the Andes, and the rivers are full. When the rivers are at their lowest, the _garua_ prevails on the coast. If these parts of the coast, however, is modified by local circumstances.

The Western Cordillera, overhanging the Peruvian coast, contains a long line of volcanic mountains, most of them inactive, but their proportions are huge. The highest of these peaks stands 21,531 m. over the level of the sea, and has been destroyed Callao, on the 28th of October, and there were 220 shocks in the following twenty-four hours. The town was overwhelmed by a vast wave, which rose 80 ft.; and the shocks continued until the following February. On the 13th of August 1868 an earthquake nearly destroyed Acre, and great waves rolled in upon the coast. A year and a half later, on the 9th of May 1877 nearly all the southern ports were overwhelmed.

The deserts between the river-valleys vary in extent, the largest being more than 70 m. across. On their western margin steep and difficultly rising sand-hills, which are often changed to or washed away on the large-scale plateau, in some places slightly undulating, in others with ridges of considerable height rising out of it. The surface is generally hard, but in many places there are large accumulations of drifting sand. The snow-line is indicated by a well-defined line of a half-moon shape, having their convex sides towards the trade-wind. They are from 10 to 20 ft. high, with an acute crest, the inner side peculiarly steep. When the wind blows with a strong force, early dawn, there is a musical noise in the desert, like the sound of distant drums, which is caused by the eddying of grains of sand in the heated atmosphere, on the crests of the medanos. Apparently the deserts are destitute of all vegetation; yet three kinds of herbs exist, which bury themselves deep in the earth, and survive long periods of drought. One is an annual plant, _plantago aristata_, and the sandhills; the other two are _Martiina_ and an _Anesia_, which maintain a subterranean existence during many years, and only produce leafy stems in those rare seasons when sufficient moisture penetrates to the roots. Where the rains are reached by moisture the trees of the desert find support, the _algarrobo_ (Prosopis horrida), a low tree of very scraggy growth, the _vickaya_ (Capparis erodium), and the _persea_ (Persea viridis) of the Cordillera and on its lower slopes a tall branched cactus is met with, and there are _Salicorniaceae_ and _Salstelas_ near the coast. But, when the mists set in, the low hills near this range undergo a change as if by magic. A blooming vegetation of wild flowers for a short time covers the barren hills. Near Lima one of the low ranges is brightened by the beautiful yellow _lilia_ called _amanes_ (Lemene Amamaes). The other flowers of the _algarrobos_ are the _papila de San Juan_ (Begonia grandifolia), with red petals contrasting with the white inner sides, valerians, the beautiful _Bomarea ovata_, several species of _Oxalis_, _Solanum_ and _crucifers_.

For purposes of description, the Coast-Region of Peru may be divided into five sections, beginning from the north: (1) the Piura region; (2) the Lambayeque and Trujillo section; (3) the Santa valleys; (4) the section from Lima to Nasca; (5) the Coast of the South America.

(1) The great desert-region of Piura extends for nearly 200 m. from the Gulf of Guayaquil to the borders of the Morrope Valley, and is traversed by three rivers—the Tumbes, Chira and Piura, the former a medium-sized stream, the last two small, running through the desert, and breaking through the outer range. It is here that the coast of South America extends farthest to the westward until it reaches Capes Blanco and Paréifa, and then turns southward to the Bay of Paita. The climate of Piura is modified by the high latitude, and also by the vicinity of the forests of Guayaquil. Fog and _garua_ are much less frequent than in the coast-region farther south, while rain sometimes falls. At intervals of three or four years there are occasional heavy showers of rain from February to April. The second section of the coast-region includes the valleys of the Morrope, the Chiclayo, and Lamaybique, the Sata, the _Jequetepeque_, the _Chicama_, Moche, Viru and Chao valleys. On this section, also extending for 200 m., contains the valleys of Santa, Nepeña, Casa, Huarmey, Fortaleza, Pativilca, Supé and Huaura. The river Santa, which rises in the lake of Conochocha, 12,907 ft. up, and Huarmey, which flows in the depression of a long course between the outer and central ranges of the Andes, is a thorough known as the "Callejon de Huaylas," 100 m. in length. It then breaks through in a deep gorge, and reaches the sea after 35 m. over a gentile and unexcelled beauty, and is the only navigable river of the coast. The Santa and Nepeña valleys are separated by a desert 8 leagues in width, on the shores of which there is a good anchorage in the bay of Ferrol, where the port of Chimbote is the terminus of the railway from the lake of Coporaque. Huarmey is a small river rises on the slope of an outer range called the Cordillera Negra, and are consequently dry during the great part of the year. Wells are dug in their beds, and the fertility of the valleys is thus maintained. The Pativilca (or Barranca) river and the Huaura break
through the outer range from their distant sources in the snowy Cordillera, and have a perennial supply of water. There are less than 40, 46 of the Nepech, from the northern tip of the Casma and Huaymey, and 18 between the Huaymey and Fortress. The latter desert, much of which is loose sand, is called the Pampa de Maia Canovas, from the numerous protected animals which wander between it and Pativilca is the desert called the Pampa del Medio Mundo. (4) The next coast-section extends for over 300 m., from Chicayac to Nasca, and includes the rivers of Chucayac, Palomitas, and a number of sea-birds, among which are the Guanaco, various penguins, and the red hoffman. The valleys of Las, Palmas, San Xavier and Nasca are rich and fertile, though they do not extend to sea, but the Andean glaciers, their deposits, the retention of ammonia and other fertilizing properties are due to the presence of rain. The islets off the coast are all barren and rocky.

The most norther is Foca, in 8° 13' 30" S., near the coast to the south of Paña. The islands of Lobos de Tierra and Lobos de Añear (2) in 8° 27' 45" S. and 8° 66' 45" S., respectively, are off the desert of Scucah, and contain deposits of guano. The two Arequipa islands are separated from the coast by the port of the same name. The islets of Macabi, in 8° 49' 20" S., also have guano deposits, now practically exhausted. The two islets of Guapaí, surrounded by many rocks, in 8° 34', contain rich deposits of guano. Chao rises 450 ft. above sea-level, off the coast, in 8° 40' 30" S. Corondo is in 8° 57' S. La Viuda is off the port of Casma, in 9° 23' 30" S.; and Tortuga is 2 m. distant to the north. Santa Islet lies off the bay of Cosca, in 9° 4' 40", and the three high rocks of Ferral in 9° 30' S. Farther south, the islet of Huanday rises in 9° 27' S., the chief of which are El Pelado, Tambillo, Chiquitana, Bruyo, Qujialacones and Mazorque. The Hormigas are in 11° 4' S. and 11° 2' S. of latitude, the so-called Titicaca, in the island of 4° 12' S., is a lofty mass, 41 m. long by 1 broad, forming the Bay of Callao; its highest point is 1005 ft. Off its south-east end lies a small lofty islet called Fronton, and to the south-west are the two islands of Pampa and Rocas. The Hormigas lie 70 m. from each other, and to the south of Callao Point. Off the valley of Lurin are the Pachacamac Islands, the most northern and largest being half a mile long. The next, called San Francisco, is like a sugar-loaf, perfectly round, and the third is called La Pampa, 8° 34', 6 mi. distant to the east, being the secondary channel of the Peruvian Cordillera.

The region of the Cordilleras of the Andes is divided into puna, or partially uninhabited wilderness, and sierra, or inhabitable mountains. The puna running south-east to north-west, consists of three chains or cordilleras. The two chains, which run parallel and near each other, on the eastern side, are of identical origin, and have been separated by the action of the water and rain. These chains are the volcanoes and many thermal springs. The narrow space between them is for the most part, but not always, a cultivated plain, known as the puna containing alpine lakes—the sources of the coast-rivers. The great eastern chain, rising from the basin of the Amazon and forming the inner wall of the system, is the Cordillera of the Andes, the central Cordillerena, the Central Cordillera, the Central Cordillerena and the Andes. See Cordillera Occidental, the Eastern Cordillera.

The western Cordillera has connection with the coast ranges of Chile, but is a continuation of the Cordillera Occidental of Chile, which under various local names forms the eastern margin of the coastal desert belt from Atacama on the northward into Peru. It is a range of volcanic islands, but with a general down-warping of the surface, and as seen from the sea, generally these volcanoes are quiescent. Further north the Misti volcano rises over the city of Arequipa in a perfect cone to a height of over 20,143 ft., and near its base are the hot sulphur and iron springs, one of which is famous for the sea-birds, and the sea-birds, and the sea-birds. A great eruption of Huaynaputina began on the 20th of February, 1845, and the beat of Volcán de Hualinara. See Cordillera de Hualinara—eastern or main branch being known as the Cordillera Nevada and the western as the Cordillera Negra. On the Nevada the peak of Huaccan reaches a height of 22,051 ft. The Nevado de Huascaran is the highest peak of Peru, rising 17,052 ft. over the valley of Yungay. It has two peaks, the highest of which, rises 19,045 ft. high, and it is the peak of this part of the chain reach a height of 19,000 ft. During the rainy season, it is not clear at dawn, and the magnificent snowy peaks are clearly seen. But as the day advances the clouds collect. In most parts of the Peruvian Andes the line of perpetual snow is at 16,400 ft.; on the Cordillera Nevada, above the Collejo de Huaylas, it sinks to 15,000 ft. This greater cold is caused by the intervention of the Cordillera Negra, which intercepts the warm air from the coast. As this lower chain does not reach the snow-line, the streams rising from it are scantly, while the Santa, Pativilca and other east-coast rivers which break through it from sources in the snowy chain have a greater volume from the melted snows. At the point where the river Santa breaks through the Cordillera Negra that begins to subside, the Cordillera continues as one chain to and beyond the frontier of Ecuador.

The Central Cordillera is the true water-parting of the system. No river, except the Marañon, breaks through it to the east or west, while more than twenty coast streams rise on its slopes and force their way through the mountain chain. The Central Cordillera consists mainly of crystalline and volcanic rocks, on each side of which are mountains, enclosing the remarkable ravine of Callao de Huaylas—the eastern or main branch being known as the Cordillera Nevada and the western as the Cordillera Negra. The peak of Huascaran, which is the highest peak of Peru, rising 17,052 ft. over the valley of Yungay. It has two peaks, the highest of which, rises 19,045 ft. high, and it is the peak of this part of the chain reach a height of 19,000 ft. During the rainy season, it is not clear at dawn, and the magnificent snowy peaks are clearly seen. But as the day advances the clouds collect. In most parts of the Peruvian Andes the line of perpetual snow is at 16,400 ft.; on the Cordillera Nevada, above the Collejo de Huaylas, it sinks to 15,000 ft. This greater cold is caused by the intervention of the Cordillera Negra, which intercepts the warm air from the coast. As this lower chain does not reach the snow-line, the streams rising from it are scantly, while the Santa, Pativilca and other east-coast rivers which break through it from sources in the snowy chain have a greater volume from the melted snows. At the point where the river Santa breaks through the Cordillera Negra that begins to subside, the Cordillera continues as one chain to and beyond the frontier of Ecuador.

The Central Cordillera is the true water-parting of the system. No river, except the Marañon, breaks through it to the east or west, while more than twenty coast streams rise on its slopes and force their way through the mountain chain. The Central Cordillera consists mainly of crystalline and volcanic rocks, on each side of which are mountains, enclosing the remarkable ravine of Callao de Huaylas—the eastern or main branch being known as the Cordillera Nevada and the western as the Cordillera Negra. The peak of Huascaran, which is the highest peak of Peru, rising 17,052 ft. over the valley of Yungay. This greater cold is caused by the intervention of the Cordillera Negra, which intercepts the warm air from the coast. As this lower chain does not reach the snow-line, the streams rising from it are scantly, while the Santa, Pativilca and other east-coast rivers which break through it from sources in the snowy chain have a greater volume from the melted snows. At the point where the river Santa breaks through the Cordillera Negra that begins to subside, the Cordillera continues as one chain to and beyond the frontier of Ecuador.
Lake Junin, or Chinchay-cocha, in the second section, is 36 m. long by 7 m. broad, and 13,323 ft. above the sea. Its marshy banks are overgrown with reeds and inhabited by numerous water-fowl. From this lake the river Xauxa flows southwards through a capricious series of rapids and gullies. It meets the river Titicaca (see BOLIVIA), in the fourth or southern section, is divided between Peru and Bolivia. It receives a number of streams from the ranges shutting in the upper end of the valley; these streams have formed lakes in the colas of Cerro Manseriche, Cerro Azangaro, both coming from the Knot of Viquireta to the north. The Suches, which has its source in Lake Suches, falls into Lake Titicaca on the north-west side, as well as the Yllpa and Ylave. The river Huallaga, which flows southwards through the peninsula of Copacabana, Campanaria (9 m. from the east shore), Soto and Esteves. There are two other lakes in the Collao, as the elevated region round Titicaca is called. Lake Anapa, a few miles north of Lake Titicaca, and on the north-west side of Lake Umayo is on higher ground to the westward. The lake in Peru which is third in size is that of Parinacochas on the coast west of the foot of the mountain (Sanmartian), long by 6 broad, but has not been visited and described by any modern traveller. The smaller lakes, often forming the sources of rivers, are numerous.

The great rivers of the Sierra are the Maranon, rising in the lake of Lauricocha and flowing northward in a deep gorge between the Maritime and Central Cordilleras for 350 m., and it forces its way through the mountains at the famous Pongo de Manseriche and another pass.

The rivers Pongo, Pasa, and, passing Huanuco, flows northwards on the other side of the Central Cordilleras for 300 m. It breaks through the range at the Pongo de Chasuta and falls into the Maranon. The other great river is the Maranon, by far the most important of its kind above the Huallaga, flow- ing from the Knot of Cerro Paso, joins the Pichachita, which is the most important northern affluent of the Uayali. The Xauxa, becoming afterwards the Mantaro, receives the drainage of Xauxa, Huallaga, and others. From the banks of this part of the Sierra furnishes streams which form the main rivers of Pampas, Pachachaca and Apurimac. These, uniting with the Mantaro, form the End, and the End and Pencen (which drains the province of Tambo) form the Tambo. The Villcamayu rises on the Knot of Viquireita, flows north through a lovely valley, received the Yanatilde and Pauarctambo on its right bank, and, with uniting with the Tambo, forms the Pausa, which is distinguished from the previous by its having foamed in a tropical climate, while the upper slopes yield products of the temperate zone, and the plateaux are above cold and bleak, affording only pasture and the hardest cereals.

The temperate and subtropical vegetation belonging to every zone. There is a tropical flora in the deep gorges, higher up a sub-tropical, then a temperate, then a sub-arctic flora. In ascending from the coast-valleys there is first an arid range in which the branch-reefed cacti rear themselves up among the rocks. Farther inland, where the rains are more plentiful, is a steppe of Achira and Pariara, and a little further down a steppe of plants with edible roots — the oca (Oxalis tuberosa), uluca (Ullucus tuberosus), massua (Tropasium tuberosum), and taroc (Polymnia spinosidea). Among the first wild shrubs and trees that are met with are the Pohon, Pohon parvipes, Pohon and the Pohon camerunensis, with beautiful red and orange flowers, several species of Senecio, calceolarias, the Schinus molle, with its graceful branches and bunches of red berries, and at higher elevations the Chusquea, the Peucem, the Lasiandra, the queñua (Buddleia incana), and the Polypeites racmosa.

The Buddleia, locally called oliva silvestre, flourishes at a height of 12,000 ft. round the shores of Lake Titicaca. The most numerous represented family is the Composite, the grasses being next in number. The temperate valleys of the Sierra yield many fruits. Those indigenous to the country are the delicious chirimoyas, pallas or alligator pears, the pacaya, a species of Ficus, the lechone, the lechow, the lemon, the taro, the balloon-shaped fruit of the Peveril, black and sugar-cane yield crops in the warmer ravines; the sub-tropical valleys are famous for splendid crops of maize; wheat and barley thrive on the mountain slopes; and at heights from 7000-9000 ft. there are many species of beans, and potatoes (Erythro- chanche). The annual produce of which is about 15,000,000 lb. The other products of these warm valleys are excellent coffee, cocoa, sugar, tropical fruits of all kinds, and gold in abundance. In the vast untrodden forests farther east there are timber trees of many kinds, immense trees, a great wealth of rubber trees of the Hevea genus, numerous varieties of beautiful palms, sarsaparilla, vanilla, ipecacuanha and copaiba. The abundant and varied fauna is the same as the flora.

Geology.—The Eastern Cordillera, which, however, is but little known, appears to consist, as in Bolivia, chiefly of Palaeozoic rocks; the western ranges of the Andes are formed of Mesozoic beds, together with numerous volcanic masses. The rocks on the western coast are composed of granite, syenite and other crystalline rocks, sometimes accompanied by limestones and sandstones, which are probably of Lower Cretaceous age, and often covered by marine fossils. The east and south of the country correspond broadly with the geological divisions.

The constitution of the Mesozoic band varies. Above Lima the western chain of the Andes is composed of porphyritic tuffs and massive limestones, while the longitudinal valley of the Maranon is hallowed in carbonaceous sandstones. From the analogy of the neighbouring countries it is possible that some of the tuffs may be Jurassic, but the other deposits probably belong for the most part to the Tertiary epoch. The bed of the Maranon has been strongly divided by the Gault fossils. Like the similar sandstone in Bolivia, it includes seams of coal and is frequently impregnated with cinnabar. It is in this sandstone that the rich mercury mines of Huancavelica are worked.

Farther north, in the department of Ancash, the Mesozoic belt is composed chiefly of sandstones and shales, and the limestones which extend westward to the ordinary limestone of Lima.

The Cordilleran Nereida in this region is in many places cut by numerous dikes of dolomite, and it is near these dikes that silver ores are chiefly

found. In the Cordillera Nevada the Mesozoic rocks which form the chain are often covered by masses of modern volcanic rock. Similar rocks are also found in the Cordillera Negra, but the volcanic centres appear to have been in the Sierra Nevada.

Population.—The first trustworthy enumeration of the people of Peru was made in 1793, when there were 617,700 Indians, 241,225 mestizos (Indian and white inter-mixture), 138,393 Spaniards, 40,337 negro slaves and 41,404 mulattos, making a total of 1,076,677 inclusive of the wild Indians of the montaña. Viceroy Toledo’s enumeration of the Indians in 1575 gave them a total of 8,000,000, the greater part of whom had been sacrificed by Spanish cruelty. Others had withdrawn into the mountains and forests, and in the native villages under Spanish administration the birth rate had dropped to a small part of what it had been because the great bulk of the male population had been segregated in the mines and on the estates of the conqueros. This tells a story of depopulation under Spanish rule, to which the abandoned terraces (andenes) on the mountain sides, once highly cultivated, bear testimony. Several diverse totals have been published as the result of the censuses taken in 1876, which is considered imperfect. One estimate places the total at 2,660,881, comprising about 13·8% whites, 57·6% Indians, 1·9% negroes, 1·9% Asians, chiefly Chinese, and 24·8% mixed races. In 1906 estimates were made under official auspices (see A. Garland, _Peru in 1906_, Lima, 1907), which gave the population as 3,547,829, including Tacna (8000). It is believed, however, that this and other larger estimates are excessive. There is no considerable immigration.

The population of Peru is mixed, including whites, Indians, Asians, and their mixtures and sub-mixtures. The dominant race is of Spanish origin, to a considerable extent mixed with Indian blood. The Indians are in great part descendents of the various tribes organized under the rule of the Incas at the time of the Spanish conquest. There are two distinct general types—the coast tribes occupying the fertile river valleys, who are employed on the plantations, in domestic service in the cities, or in small industries of their own, no longer numerous; and the sierra tribes, who are agriculturists, miners, stock-breeders and packers, still comparatively numerous. In addition to these are the tribes of wild Indians of the montaña region, or eastern forests, who were never under Inca rule and are still practically independent. Their number is estimated at 150,000 to 300,000. They are divided into a large number of small communities with their own customs and material condition. Some live in settled communities and roughly cultivate the soil. Others are hunters and fishermen and are nomadic in habit. Others are intractable forest tribes, having no relations with the whites. The sierra or upland Indians, the most numerous and strongest type, belong largely to the Quichua and Aymará families, the former inhabiting the regions northward of Cuzco, and the latter occupying the Titicaca basin and the sierras of Bolivia. These Indians are generally described as Cholas, a name sometimes mistakenly applied to the mestizos, while the tribes of the eastern forests are called Chunchos, barbaros, or simply Indians. The Cholas may be roughly estimated at about 1,000,000 in number, or the larger part of the sierra population. Practically all the industries and occupations of this extensive region depend upon them for labourers and servants.

The mestizos are of mixed Spanish and Indian blood. There are two general classes—the costeños or those of the coast, and the serranos or those of the sierras. The mestizos of the coast are usually traders, artisans, overseers, petty officers and clerks, and small politicians. In the sierras they have the same general occupations, but there are no social bars to their advancement, and they become lawyers, physicians, priests, merchants, officials and capitalists. The African and Asiatic elements furnish only about 2·% of the population. The Africans were divided and settled on the coast about two years after the conquest, because the coast Indians were physically incapable of performing the work required of them on the sugar estates. All the heavy labour in the coast provinces was performed by them down to 1855, when African slavery was abolished. They have since preferred to live in the towns, although many continue on the plantations. The first Chinese coolies were introduced in 1849 to supply labourers on the sugar estates, which had begun to feel the effects of the suppression of the African slave trade. At first the coolies were treated with cruelty. The scandals that resulted led to investigations and the abolition of their restriction. The Chinese have become to a large extent a matter of voluntary contract, usually for two years. This is a fair dealing and good treatment are the rule. Many Chinese are also settled in the coast cities. Commercial relations have also been opened with Japan, and a small Japanese colony has been added to the population. The Spanish and African coast is to be seen in the mulattos, quadroons and octoroons that inhabit the warm coast cities. Other race mixtures consist of the zimboz (the African-Indian cross), an Asiatic graft upon these various crosses, and an extremely confusing intermixture of the various crosses, for which the Spanish races have descriptive appellations. The foreign population is chiefly concentrated in Lima and Callao, though mining and other industries have drawn small contingents to other places.

Education.—Universities and colleges were founded in Peru soon after the conquest, and Lima, Cuzco, Arequipa and Chiquisaca (now the Bolivian town of Sucre) became centres of considerable intellectual activity. Secondary schools were founded for the benefit of the Indian “nobility,” schools being created at Lima and Cuzco. The university of San Marcos at Lima is the oldest collegiate institution in the New World, originating in a grant from Charles V. in 1551 to the Franciscans for the education of the Indians. The university, however, was founded at Lima. Its present name, however, was not adopted until 1754, two years after its first secular rector had been chosen. The college of San Carlos was created in Caracas, in the Spanish colony of Venezuela, in 1792. At Cuzco the university of San Antonio Abad was founded in 1598, and the college of San Geronimo at Arequipa in 1616. The instruction given in these institutions was of the religious and scholastic character of that time, and was wholly under the supervision of the Church. Independence opened the way for a larger measure of intellectual and educational progress, especially for the lower classes. As organized under the law of the 5th of February, 1824, primary instruction is free and compulsory and is under the control of the national government. The primary schools are divided into two grades: a free elementary course of two years, and a higher course of three years, in a school called the Instituto. There is also a normal school, which is divided into two schools: the Instituto at Lima and the San Marcos at Arequipa. There were 1408 elementary schools and 862 scholastic centres in 1906. There are, besides these, a large number of private schools, which in 1906 carried about 22,000 pupils on their rolls, or three times the number in the public primary schools. To provide teachers six normal schools have been established, two of which (one for males and one for females) are in Lima. For intermediate or secondary instruction there are national, departmental, provincial, city, and private schools, and three similar colleges for girls, in Ayacucho, Cuzco and Trujillo. In these the majority of pupils were under the direction of Belgian and German instructors. The private schools of Lima are still under the control of the Church, and are of the same kind as those that belong to the same category. For higher instruction there are four universities: the Universidad Mayor de San Marcos at Lima, and three provincial institutions at Arequipa, Cuzco and Trujillo. All these have faculties of letters and law, and San Marcos has in addition faculties of theology, medicine, mathematics and science, philosophy and administrative and political economy. The professional schools include a school of civil and mining engineering at Lima (created 1876), a military school at Chorrillos under the direction of French instructors, a naval school at Callao, nine episcopal seminaries (one for each diocese), a national agricultural school in the vicinity of Lima (created 1902), and a few commercial and technical institutes. There is also a national school of marine and naval devoted to the education and training of youthful delinquents.

Science and Literature.—Towards the end of the 18th century scientific studies began to receive attention in Peru. M. Godoy, a member of the French Academy, began for measuring an arc of the meridian near Quito, became professor of mathematics at San Marcos in 1790; and the botanical expeditions sent out from Spain gave rise to scientific studies. From 1906 to 1910, Dr. Godoy, a native of Huamantanga in the Maritime Cordilleras, studied under Dr Jussieu, and became an eminent botanist. Don Hippolyto Unanue, born at Arica in 1755, was an important work on the flora of the coast. The first edition of this, prepared by Dr A. M. Lina and published in 1793, was in the time when the periodical was started in 1791 at Lima, the contributors forming a society called “amantes del pais,” and it was completed in eleven volumes. It contains many valuable articles on history, topography, agriculture, commerce, and other matters, and its appearance to Peru was begun by the learned geographer Dr Cosme Bueno, and continued by Dr Unanue, who brought out his guides at Lima from 1793 to 1798. In 1794, a nautical school was founded at Lima, with Andrés Baleato as instructor and Pedro Alvarez as teacher of the use of instruments. Baleato also constructed a map of Peru.
A list of Peruvian authors in viceroyal times occupies a long chapter in the life of Sr Toribio by Montalvo; and the bibliographical labours of the Peruvian Leon Pinelo are still invaluable to Spanish students. The most prolific author of colonial times was Dr Pedro de Althaus Barrancos, who produced more than sixty works, including an epic poem entitled Lima fundada.

The topographical labours of Cosme Bueno and Unanue were admirably continued at Lima by Admiral Don Eduardo Carrasco, who compiled the first general topography of the Peruvian territory. The Peruvian geographer is Dr Don Mariano Felipe Paz Soldan (1821-1886), whose Geografía del Peru appeared in 1861. His still more important and comprehensive Geografía General del Peru, written in 1886, is in progress on a most impressive scale. In 1886 appeared his first volume of the Historia de Peru independiente, and two others have since been published. His Historia de la guerra del Pacífico is the Peruvian contribution to the study of one of the greatest battles ever fought. Peru has been written in three volumes by Sebastian Lorente (d. 1884); Mariano Rivero has discussed its antiquities; and Manuel Fuentes has edited six volumes of memoirs written by Spanish viceroys. But the most poetical and important of the modern Peruvians is General Mendiburu's Diccionario historico-biografico del Peru, a monument of patient and conscientious research, combined with critical discrimination of a high order. As laborious historical students, Don José Toribio Polo, the author of an ecclesiastical history of Peruvian dioceses, and Don Enrique Torres Saldamando, the historian of the Jesuits in Peru, have great merit. Among good local annalists may be mentioned Juan Gilberto Vargas, who wrote important studies concerning the life and labours of Vitoria, and the learned Padre Jose de Altimas, the author of the Annals of Zuzos.

The leading Peruvian authors on constitutional and legal subjects are Dr José Santisteban, who has published volumes on civil and criminal law; and Don Pedro del Villar (d. 1882), a lawyer, secretary at Lima), a work on constitutional right; Dr Francisco Garcia Calderon (once president of Peru), author of a dictionary of Peruvian law; and last, but by no means least, the learned Don Miguel Arceguí, one of the fathers of Peruvian independence; and Dr Francisco Paula Vigil (1792-1875), orator and statesman as well as author, whose work, Defensa de los gobiernos, is a noble and enlightened statement of the case for civil governments against the pretensions of the Holy See. Manuel A. Fuentes, an able statistician and the author of the Estadistica de Lima, has also written a manual of parliamentary practice. Perhaps the most important work on Peru of modern times is the Institute of Lima (1825-1890), who spent the greater part of his life in studying the topography and natural resources of the country. Only four volumes had been published at the time of his death, but he left a mass of papers and manuscripts which the government has put in the hands of the Geographical Society of Lima for publication. His great work is entitled El Peru: estudios minero-legales, &c. (3 vols., Lima, 1890-1902), and one separate volume on the department of Ancachs.

Peruvian literature since the independence has also attained high merit in the walks of poetry and romance. The Guayaquil author, Olmedo, who wrote the famous ode on the victory of Janin, and the Linienese Felipe Pardo and Manuel Segura and later on Benigno de Segura, have written in the vernacular language. Both died between 1860 and 1870. The comedies of Segura on the customs of Lima society, entitled Un Paseo a Amancas and La Saya y Marco, have no equal in the dramatic literature of Spanish America. More modern and modernistic, however, are the poetical efforts of Arnoldo Marquez, who is distinguished for his correct diction and rich imagination, as is Nicolas Corpancho for his drollery. Alcide Maradiaga for his beautiful sonnet to Bolivar, which was published at Havre in 1870, in his one volume of poems, and Clemente Atahual for his productivity and style. Pedro Paz Soldan was a classical scholar who published three volumes of poems. Carlos Augusto Salaverry, known as one of Peru's best lyric poets, and Luis Benjamin Cisneros for his two novels, Julia y Edgardo, Trinidad Fernandez and Constantinio Carrasco were two poets of whom died young; the latter's work, together with the publications of his contemporaries Quichua drama, Ollantay, José Antonio Lavalle and Narciso Arceguí are chiefly known as novelists. In his youth Ricardo Palma published three books of poems, entitled Armolmas, Verbas y Gerundios and Pasionarios, and, since 1870, devoted his great literary talents to writing the historical traditions of Peru, of which six volumes were published. At the outbreak of the war with Chile he was vice-director of the national library at Lima, which was burned and lost, and the greater part of his works were lost in the fire. At the same time Lima by the Chileans Palma devoted his life to the recovery of his scattered books and the acquisition of new collections, and he had the satisfaction before his death of re-opening the library, which had been destroyed. The volume contains four-nineteenth of the number on its shelves before the Chilean invasion.

Of the aboriginal inhabitants of Peru much has been written. The important work of Mariano Eduardo Rivera, of Arequipa, assisted by J. J. von Tschudi, on the antiquities of Peru (Antiguades peruanas, Vienna, 1841; Eng. trans., New York, 1853) has been followed by other investigators into the language, literature, customs and religion of the Incas. The best known of these are the works of Bernardo de Molina, of Arequipa, and of several of the missionaries, such as Domingo Fernandez Nodal, and Cavino Pacheco Zegarra of Cuzco, who published translations of the Inca drama Ollantay, and Leonardo Vicente Vargas of Cuzco.

Among Peruvian naturalists since the advent of the republic, the most distinguished have been Mariano Eduardo Rivero, the geologist, mineralogist and archaeologist, and his friend and colleague Benigno de Segura, who was a disciple of Dr Mendiburu. The Lima Geographical Society (founded in 1888) is perhaps the best and most active scientific organization in the republic. Its special work covers national geographical exploration and study, archaeological researches and excavation, and the improvement of geographical and topographical information. The society receives a government subsidy, and its rooms in the national library in Lima are the principal centre of scientific study in Peru. It had an active membership of 163 in 1906, besides 172 honorary and corresponding members.

The historical institute of Peru, also at Lima, is charged by the government, from which it receives a liberal subsidy, with the work of collecting, preparing and publishing documents relating to Peruvian history, and of preserving objects of archaeological and historic character. Its museum, which is of great historical and artistic value and includes a collection of portraits of the Peruvian viceroys and presidents, is in the upper floors of the Exposition Palace. Another institute is the University; a national library, founded in 1877 as the "literary club," and reorganized in 1887 under its present title. Its purpose is to foster learning and literary effort, and it is a popular and prominent feature in the intellectual life of the country.

Religion.—According to the constitution of 1860 "the nation professes the apostolic Roman Catholic religion; the state protects and encourages it, and does not permit any other sects." Although there is a certain degree of tolerance, however, and the Anglican and some of the evangelical churches are permitted to establish missions in the country, but not always without hostile demonstrations from the Catholic priesthood. There are Anglican churches in Lima and Cuzco, belonging to the diocese of the Bishop of the Falkland Islands; but their existence is illegal and is ignored rather than permitted. In its ecclesiastical organization Peru is divided into nine dioceses: Lima, Cuzco, Arequipa, Huancayo, Huaro, Trujillo and Chachapoyas. These dioceses are subdivided into 613 curacies, presided over by curas, or curate-vicars. Each diocese has its seminary for the education of the priests of that Archdiocese and its influence in church matters. There are a number of fine churches in Lima and in the sees of the various dioceses. Monasteries and nunneries are numerous, dating back to the 16th and 17th centuries, but their influence is now less potent than in those days and the monastic life is not so flourishing as in the earlier times of the convents. Many of the convents have been devoted to educational work especially for girls, which is an obstacle to the successful development of a public school system in the country.

Political Divisions.—The empire of the Incas was divided into four main divisions, Chinchay-suyu to the north of Cuzco, Anti-suyu to the east, Colla-suyu to the south and Cunti-suyu to the west, the whole empire being called Tahuantin-suyu, or the four governments. Each was ruled by a governor, under whom were the "huaranca-camayocas," or officers ruling over thousands, and inferior officers, in regular order, over 500, 100 and 50 men. All disorders and irregularities were checked by the periodical visits of the tucuyiros or inspectors. The Spanish conquest destroyed this complicated system. In 1569 the governor, Lope Garcia de Castro, divided Peru into corregimientos under officers named corregidores, of whom there were 77, each in direct communication with the government at Lima. An important administrative reform was made in 1784, when Peru was divided into 7 intendencias, each under an officer called an intendente. These intendencias included about 6 of the old corregimientos, which were called partidos, under officers named subintendentes. Thus the number of intendencias was reduced from 77 to 7, a great improvement. The republic adopted the same system, calling the intendencias departments, under a prefect, and the partidos provinces, under a sub-prefect. Peru is divided into 18 departments, 2 littoral provinces, and what is called the constitutional province of Callao. This is exclusive of Tacna and its 3 provinces. The departments, which contain 98 provinces, with their areas, capitals and estimated populations of 1906, are as follows: the
Apart from the departmental capitals there are few towns of size and importance. The so-called coast towns are commonly at some distance from the seashore, and their shipping ports are little more than a straggling collection of wretched habitations in the vicinity of the landing-stage and its offices and warehouses. Callao (q.v.) is a noteworthy exception, and Paita and Pisco are something more than the average coast village. Near Lima, on the south, there are three bathing resorts, Chorrillos, Miraflores and Barranco, which have handsome residences and large populations in the winter season. South of Lima is the port and bathing resort of Ancon, in an extremely arid locality but having a fine beach, a healthy climate and a considerable population in the season. The towns of the coast region are usually built on the same general plan, the streets crossing each other at right angles and enclosing squares, or quadrages. In the sierra there is the same regular plan wherever the site is level enough. High-pitched red tiled roofs take the place of the flat roofs of the coast. The upper story often recedes, leaving wide corridors under the overhanging caves, and in the "plazas" there are frequently covered arcades. In addition to the capitals of the departments, Tarma (about 6,000 feet), Xaixi, and Ilo (about 200 feet) are other important towns of this region. In the montaña there are no towns of importance other than the capitals of the departments and the small river ports.

Communications.—The problem of easy and cheap transportation between the coast and the interior has been a vital one for Peru, for upon it depends the economic development of some of the richest parts of the republic. The arid character of the coastal zone, with an average width of about 80 m., permits cultivation of the soil only where water for irrigation is available. Only in the sierra and montaña regions is it possible to maintain a large population and develop the industries upon which their success as a nation depends. During colonial times and down to the middle of the 19th century pack animals were the only means of transport across the desert and over the rough mountain trails. Railway construction in Peru began in 1848 with a short line from Callao to Lima, but the building of railway lines across the desert to the inland towns of the fertile river valleys and the Andean foot of the desert did not begin until twenty years later. These roads added much to the productive resources of the country, but their extension to the sierra districts was still a vital necessity. Under the administration (1868-1872) of President José Balta the construction of two transAndean railroad lines was begun, but their completion became impossible for want of funds. Balta's plans covered 1,281 m. of state railways and 749 m. of private lines, the estimated cost to be about $47,800,000—a sum far beyond the resources of the republic. The two transAndean lines were the famous Oroya railway, running from Callao to Oroya (1893), which crosses the Western Cordillera at an elevation of 16,645 ft., and later on to Cerro de Pasco (1904), the Goñillasquiza coal mines (1904) and Hauri (1906); and the southern line from Mollendo to Lake Titicaca, which reached Arequipa in 1896, Puno in 1871 and Checcacui (Cuzco branch) in 1906. Surveys were completed in 1897 for an extension from Lake Titicaca through Arequipa and Puno to the Portuguese border. From Puno to the mouth of the river the line is 20,000 m. of connected railways navigable at high water for all descriptions of boats, or 10,000 m. for steamers of 20 to 2 ft. draught, which is reduced to $800 m. at low water. The rivers forming the coast usually are not navigable for more than 20 m. of steamers, but those of the Brazilian frontier (484 m.), the Japurá, Putumayo, Javary, Napo, Tigre, Huallaga, Ucayali, Pachita, Juruá, Purus, Acre, Curaray and Aguaytia all navigable over part of their courses of about 200 m. of river. The most important means of communication in the republic is that of its river system, comprising, as it does, the navigable channels of the Marañón, or upper Amazon, and its tributaries. In 1870 the following estimates of the navigable reaches were made: 14,000 m. for steamers of 20 to 2 ft. draught. On the left fork of the Marañón, it is claimed that steamers of 20 ft. draught can ascend to Puerto Limón at all seasons of the year. The inclusion of the upper waters of the Brazilian rivers Juruá, Purús and Acre pro forma only, as they are wholly under Brazilian jurisdiction. Practically the whole of the region through which these rivers run—the montaña of Peru—is undeveloped, and is inhabited by Indians, with few settlements of whites on the river courses, except the port is Iquitos, on the Marañón, 335 m. above the Brazilian frontier and 2653 m. from the mouth of the Amazon. It is visited by ocean-going steamers, and is the centre of the Peruvian river transport in the upper system, and is also of great importance as the port for the navigation of Lake Marañón, on which steamers ply regularly between Puno and Iquitos. A little last on the coastal shore, and across the river with La Paz, the capital of Bolivia. This is one of the most remarkable river steamers in the world, being 13,570 ft. above sea-level. The lake is 165 m. long and from 70 to 80 m. wide and has a depth of 324 ft. in some parts. There are two submarine cable lines on the Peruvian coast—the (American) Central and South American Co., extending from Panama to Valparaíso, and the (British) West Coast Cable Co., subsidiary to the Eastern Telegraph Co., with a cable between Callao and Valparaiso. The inland telegraph service dates from 1864, when a short line from Callao to Lima was constructed, and state ownership from 1875, when the government assumed control of the line which had been worked up to 1872. Since then it has been handed over to private administration. They connect all the important cities, towns and ports, but cover only a small part of the region. The construction of a telegraph service in the sierra and montaña regions is too great to permit their extensive use, and the government is seeking to substitute wireless telegraphy. From Puerto Bermúdez, on the Pacific or Pichis line, a wireless station is in operation using the Marañón as a closed wireless system connects with Massisena on the Ucayali, and thence with Iquitos, on the Marañón—a distance of 930 m. by steamer, which is much shortened by direct communication between the three great telegraphic stations. This service was opened to Iquitos on the 8th of July 1908, the first section between Puerto Bermúdez and Massisena having been pronounced a success. The Peruvian telegraph system connects with those of Ecuador and Bolivia. Peru has about 5,000 miles of telegraph lines. The postal service is that an extra charge of 2 cents for each letter and 1 cent for each post-card is collected when they are sent across the isthmus of Panama. No charge is made for the transmission of telegrams. The post-office system is national, but the mail service is that an extra charge of 2 cents for each letter and 1 cent for each post-card is collected when they are sent across the isthmus of Panama. No charge is made for the transmission of telegrams. The post-office system is national, but the national post-office, which has been slow and erratic. There are many ports on the coast, but only eight of them are rated as first class, viz. Paita, Eten, Pucamayo, Salaverry, Callao, Pisco, Mollendo and Chao, of which are ports of call for foreign coasting steamers. The inland port of Iquitos, on the Marañón, is also rated as first class, and enjoys special privileges because of its distance from the national

capital. The second-class ports are Tumbes, Talara, Pimentel, Chimbote, Sumanclo, Casma, Huacho, Cerro-Azul, Tambo de Mora, Lomas and Chala, on the coast, Puno on Lake Titicaca, and Leoncio Prado on the Callao (q.v.) is the chief port of the republic and monopolizes the greater part of its foreign trade. It has, however, the advantage of not being the only port works begun under the administration of President Balta. Paita and Chimbote have good natural harbours, but the others, for the most part, are open roadsteads or unsheltered bays. Motilón at a station on the line for the terminus at this railway from Puno. There were 12 foreign steamship lines trading at Peruvian ports in 1908, some of them making regular trips up and down the coast at frequent intervals and carrying much of its coastwise trade. The steamer business in 1906, and the exports of foreign goods, permitted to engage in this traffic, but permission is given to steamships on application and under certain conditions. The imports were valued in 1907 at £14,780,970 sterling (to soles=$1.12 s.g.) and the exports at £8,331,399 (to soles=$1.25 s.g.). The imports of rice, sugar, coca, hides and skins, rubber and forest products, greatly exceeded the Mississippi imports. The most important export is sugar, the products of the rice ranking second. The largest share in Peru's foreign trade is taken by Great Britain, Chile ranking second and the United States third.

Products.—Although her mining industries have been the longest and most widely known, the principal source of Peru's wealth is agriculture. This seems incompatible with the arid character of the country, but all-region irrigation has been successfully employed in the fertile valleys of the coast.

Agriculture.—Sugar-cane is cultivated in most of the coast valleys, and has its pre-eminence in those of the Canete, Rimac, Chancay, Huaura, Supe, Santa, Chicama, Pascasuyo and Chichayo. Some of the large estates are owned and worked by British subjects. The industry was nearly ruined by the Chinchimayo, but its reestablishment after the war and the war and this has been steadily increasing. At the outbreak of the war the production was about 80,000 tons; in 1905 the production of sugar and molasses amounted to 161,854 metric tons, of which 150,000 were exported. In 1906 the total production reached 169,418 metric tons. Next in importance is cotton, which is grown along the greater part of the Peruvian coast, but chiefly in the departments of Lima and the Callao. Some is grown in the latter province, but the coca and "vegetable wool," sea island, brown or Miltaffi, and smooth or American. Production is steadily increasing, the export having been 8,000 metric tons in 1908, 17,386 in 1905 and 29,000 in 1906. The wool is in large demand in all parts of the world, and is the export of wool in 1905 exceeded 3,000,000 lb. The rearing of these animals requires much patience and skill, in which no one has been able to match the Indian breeders of the Andean plateau.

The natural products of Peru include rubber, cabinet woods in great variety, cinchona or Peruvian bark and other medicinal products, various fibres, and guano. There are two kinds of rubber, the one rubber used in the United States for making the Chinchimayo forests: febe (also written bebe) or seringa, and caucho—the former being collected from the Hevea guayanaensis, or H. robusta (that of the Guiana), and the latter from species of Ceiba and some other varieties. The Hevea product is obtained annually by tapping the trees and coagulating the sap over a smoky fire, but the caucho is procured by felling the tree and collecting the sap in a hollow in the butt, where it is converted into a strong gelatin and dried, and the juice of a plant called setilla. As the species from which Ceara rubber is obtained (Hancorania speciosa) is found in Bolivia, it is probable that this is also a source of the Peruvian caucho. The Hevea is found along the water-courses of the lowlands, which includes the large tributaries of the Marañon, while the caucho species flourish on higher ground, above 900 ft. elevation. Owing to the export tax on rubber (8 cents per kilogram on febe and 5 cents per kilogram on caucho) the country has been able to limit the amount of rubber produced. In 1904 the total production, which was returned as 2559 metric tons in 1905, valued at $13,989. The export of cinchona, or Peruvian bark, is not important in itself, being only 64 tons, valued at $2,134 in 1905. In 1880 Peru was the chief producer of cinchona in the world, but its production has since declined. It is cultivated in the eastern Peru, but it is found in many localities on the eastern slopes of the Andes. The Peruvian supply is practically exhausted through the destructive methods employed in collecting the bark, and the world now depends chiefly on Bolivia and Ecuador. The forests of eastern Peru are rich in fine cabinet woods, but their inaccessibility renders them of no great value. Among the best known woods are Oxydendron guineense, or Oxydendron palmatus, and the peach palm (Guillemia speciosa).

From guano an immense revenue was derived during the third quarter of the 19th century and it is still one of the largest exports. It is found only among the barren cliffs and islands of the Pacifc coast. They were developed commercially during the administration (1845-1851) of President Ramon Castillo, at the same time that the nitrate deposits of Tarapaca became a
commercial asset of the republic. The large revenues derived from these sources undoubtedly became a cause of weakness and demoralization and eventually resulted in bankruptcy and the loss of Peru. The silver production has largely subsided, and for large shipments of over a half-century, but the export in 1905 was 73,165 tons, valued at $285,729.

Mining—Mining was the chief industry of Peru under Spanish rule. The agricultural and pastoral people, but the abundance of gold and silver in their possession at the time of the conquest shows that mining must have received considerable attention. They used these precious metals mostly for decoration and ornament, and with the assistance of Indian slaves thousands of mines were opened, many of them failures, some of them becoming famous. There was a decline in mining enterprise after the revolt of the colonies, and the waning of Spanish rule, owing to the unsettled state of the country, and this decline continued in some measure to the end of the century. The mining laws of the colonial régime and political disorder together raised a barrier to the employment of the laborer, fortune capital needed, while the frequent outbreaks of civil war made it impossible to work any large enterprise because of its interference with labour and the free use of ports and roads. The Peruvians were impoverished, and under such conditions foreign capital could not be expected. In 1876 new mining laws were enacted which gave better titles to mining properties and better regulations for their operation, but the outbreak of the war with Chile during the same year and the depression which such a war created disorganized and partisan strife defeated their purpose. Another new mining code was adopted in 1901, and this, with an improvement in political and economic conditions, has led to a renewal of mining enterprise.

Practically the whole Andean region of Peru is mineral-bearing—a region 1500 m. long by 200 to 300 m. wide. Within these limits are to be found most of the minerals known—gold, silver, quicksilver, copper, lead, zinc, iron, manganese, wolfram, bismuth, thorium, vanadium, mica, coal, &c. On or near the coast are coal, salt, sulphur, borax, nitrates and petroleum. Gold is found in lodes and alluvial deposit; the former on the Pacific slope at Salgo, Cuzco, Cajamarca, and the department of Cañete; the latter in the Andaray and Arequipa, and on the table-lands and Amazon slope at Patz, Huancaro, Chiquitambo, Huancaveca, Cuzco, Cotabambas, Ayarmas, Paucartambo, and Cuzco, and Morococha, and on the Amazon slope, in the country about the Pongo de Manzaniere and at Chiquibamba, both on the upper Maranon, in the districts of Patz, Huancaco, Ayarmas and Anta, and other places. The latter wholly on the Amazon slope, and in the country about the Pongo de Manzaniere and at Chiquibamba, both on the upper Maranon, in the districts of Patz, Huancaco, Ayarmas and Anta.

The Aporoma deposit, in the district of Sandia, is the best known. Long ditches with stone-paved sluices for washing this mineral-bearing material have long been used by the Indians, who at the latter wholly on the Amazon slope, and in the country about the Pongo de Manzaniere and at Chiquibamba, both on the upper Maranon, in the districts of Patz, Huancaco, Ayarmas and Anta, are obtained from the Incas deposits and gold mines.

The Pampas. The Pampas, or pampas of Titicaca, is known. The number of mines worked is small and there is not much foreign capital invested in them. The gold ores of Peru are usually found in ferruginous quartz. The production in 1906 was valued at $150,000.

Peru has been known chiefly for its silver mines, some of which have been marvellously productive. The Cerro de Pasco district, with its 342 mines, is credited with a production in value of $40,000,000 between 1784 and 1888, and is still productive, the output for 1906 being valued at $972,058. The principal silver-producing districts, the greater part on the high table-lands and shallow basins, are Huanca, Huancayo, Huayan, Recuay, Cajamarca, Morococha, Huanorochi, Huancaveca, Quispisipa, Castro-virey, Lucanas, Lampa, Caylima and Puno, and there are hundreds of others outside their limits. Silver is generally found as red oxides (locally called rositer), sulphides and argentiferous galena. Modern machinery is little used and many mines are practically unworkable for want of pumps. In the vicinity of some of the larger productive mines the ore is so rich that the working of it is uneconomical, and timber is scarce on the table-lands. The dried dung of the llama (tupia) is generally used as fuel, as in pre-Spanish times, for roasting ores, as also a species of grass called tchu (Sibarite utilis), and a similar one called cebu (Sibarite umbellifera), which grows on the rocks at elevations exceeding 12,000 ft. The methods formerly employed in reducing ores were lixiviation and amalgamation, but the latter is now gradually being replaced by cyanidation into use. Quicksilver is found at Huancaveca, Chonta (Aneacha), and in the department of Puno. The mine first named has been worked since 1566 and its total production is estimated at 60,000 tons, the annual product being about 670 tons for a long period. The metal generally occurs as sulphide of mercury (cinnabar), but the ores vary greatly in richness—from 23 to 20%. The metal is smelted at the mine, and then exported from the port of Lima, with the exception of a small amount which is exported directly through the port of Callao.

Government.—Peru is a centralized republic, whose supreme law is the constitution of 1860. Like the other states of South America its constitution provides for popular control of legislation and the execution of the laws through free elections and comparatively short terms of office, but in practice these safeguards are often set aside and dictatorial methods supersede all others. Namely the people are free and exercise...
sovereign rights in the choice of their representatives, but the ignorance of the masses, their apathy, poverty and dependence upon the great land proprieters and industrial corporations practically defeat these fundamental constitutional provisions. Citizenship is accorded to all Peruvians over the age of 21 and to all married men under that age, and the right of suffrage to all citizens who can read and write, or possess real estate or workshops, or pay taxes. In all cases the exercise of citizenship is regulated by law.

The government is divided into three independent branches, legislative, executive and judicial, of which through force of circumstances the executive has become the dominating power. The executive branch consists of a president and two vice-presidents elected for terms of four years, a cabinet of six ministers of state appointed by the president, and various subordinate officials who are under the direct orders of the president. The president is chosen by a direct popular election and cannot be re-elected to succeed himself. He must be not less than 33 years of age, a Peruvian by birth, in the enjoyment of all his civil rights, and domiciled in the republic ten years preceding the election. The immediate supervision and despatch of public administrative affairs is in the hands of the cabinet ministers—interior, foreign affairs, war and marine, finance and commerce, justice and public instruction, and public works and promotion (fomento). The execution of the laws in the departments and provinces, as well as the maintenance of public order, is entrusted to prefects and sub-prefects, who are appointees of the president. A vacancy in the office of president is filled by one of the two vice-presidents elected at the same time and under the same conditions. Inability of the first vice-president to assume the office opens the way for the second vice-president, who becomes acting president until a successor is selected. The vice-presidents cannot be candidates for the presidency during their occupancy of the supreme executive office, nor can the ministers of state, nor the general-in-chief of the army, while in the exercise of their official duties.

The legislative power is exercised by a national Congress—senate and chamber of deputies—meeting annually on the 28th of July in ordinary session for a period of 90 days. Senators and deputies are inviolable in the exercise of their duties, and cannot be arrested or imprisoned during a session of Congress, including the month preceding and following the session, except in flagrante delicto. Members of Congress are forbidden to accept any employment or benefit from the executive. Senators and deputies are elected by direct vote—the former by department and province, the latter in nomination from the population. With both are elected an equal number of substitutes, who assume office in case of vacancy.

Departments with eight and more provinces are entitled to four senators, those of four to seven provinces three senators, those of two to three provinces two senators, and those of one province one senator. The deputies are chosen to represent 15,000 to 30,000 population each, but every province must have at least one deputy. Both senators and deputies are elected for terms of six years, and both must be native-born Peruvian citizens in the full enjoyment of their civil rights. A senator must be 35 years of age, and have a yearly income of $1,000. The age limit of a deputy is 25 years, and his income must be not less than $500. In both chambers the members are elected by the people of the several constituencies, which are proportioned to the population of the districts, and are representative in lieu of the pecuniary income. No member of the executive branch of the government (president, cabinet minister, prefect, sub-prefect, or governor) can be elected to either chamber, nor can any judge or "fiscal" of the supreme court, nor any member of the ecclesiastical hierarchy from his diocese, province or parish, nor any judge or "fiscal" of superior and first-instance courts from their judicial districts, nor any military officer from the district where he has been stationed as regimental officer at the time of his election at the expense of the state, or other public office, or the right to comment with Congress within a period of ten days. Should the act be again passed without amendments it becomes law; if, however, the senators and deputies are acceptable to the national chamber, it must pass to the next session. Congress may also sit as a court of impeachment—"the senate hearing and deciding the case, and the chamber acting as prosecutor. The president, ministers of state and judges of the supreme court may be brought before this court.

Justice.—The judiciary is composed of a supreme court, superior courts and courts of first instance, and justices of the peace. The supreme court consists of the president of the supreme court, the court of the Chamber of 11 judges and 2 "fiscals" or prosecutors. The judges are selected by Congress from lists of nominees submitted by the executive. The judges of the superior courts are chosen by the president from the list of nominees submitted by Congress. Questions of jurisdiction between the superior and supreme courts, as well as questions of like character between the supreme court and the executive, are decided by the senate sitting as a court of last resort. All other cases are heard before the courts of the districts in which they are located. The independence of the Peruvian courts has not been scrupulously maintained, and there has been much criticism of their character and decisions.

The national executive appoints and removes the prefects of the departments and the sub-prefects of the provinces, and the sub-prefects of the districts. The sub-prefects of the districts, the judges, and all officials throughout the republic are also appointees of the president and are under his orders.

Army.—After the Chilean War the disorders fomented by the great enterprises and in corrupt practice. This was followed by a reduction in public affairs under civil control. This led to a material reduction in the army, which, as reorganized, consists of 4,000 officers and men, divided into seven battalions of infantry of 300 men each, seven squadrons of cavalry of 125 men each, and one regiment of mountain artillery of 500 men, with six batteries of mountain guns. The reorganization of the army was carried out by 10 officers and 4 non-coms. of the French army, known as the French military guidance service, who are in charge of the training school at Chorrillos and all branches of military instruction. There are a military high school, preparatory school, and "school of application" in conjunction with the training of young officers for the army. The head of the military government is the finance minister. The Indians were forcibly pressed into the service and the whites filled the positions of officers, in great part untrained. Now military service is obligatory for all Peruvians between the ages of 19 and 50, who are divided into four classes, first and second reserves (19 to 30 and 30 to 35 years), supernumeraries (those who have purchased exemption from service in the regular army), and the national guard (35 to 50 years). The regular force is maintained by annual drawings from the lists of young men 10 years of age in the first reserves, who are required to serve four years. The direction of military affairs is entrusted to a general staff, which is organized in the lines adopted by the British and other military powers of Europe. The republic is divided into four military districts with headquarters at Piura, Lima, Arequipa and Iquitos, and these into eleven circumscriptions. The mounted police force of the republic is also organized on a military basis.

Justice.—The Peruvian navy was practically annihilated in the war with Chile, and the poverty of the country prevented for many years the adoption of any measure for its rebuilding. In 1903 it was decided to purchase from France the only naval vessel of the nation, the "Hercules," and to have the direction of an officer of the French navy. In addition to the foregoing the government has a small river boats on the Maranon and the Ucayali. Under navigation laws and the control of the navy, various posts are maintained to maintain the authority of the republic and carry on geographical and hydrographical work.

Finance.—The financial record of Peru, notwithstanding her unprecedented natural resources, is unsatisfactory. The internal strife at first prevented the development of her resources, and then when the export of guano and nitrates supplied her treasury with an abundance of fund's the money was squandered on extravagant enterprises and in corrupt practice. The government then had to readjust expenditures to largely diminished resources; the result of these measures was an alleviation of the situation, but not a solution of the problem, and since 1895 there has been an improvement in the financial state of the country. The public revenues are derived from customs, taxes, various inland consumption and state taxes, state monopolies, internal taxes, the sales of property of the state, and local taxes. The public expenditures include import and export duties, surcharges, harbour dues, warehouse charges, &c.; the inland taxes comprise consumption taxes on alcohol, tobacco, sugar and matches, stamps and temperance, capital and mining properties, licences, transfers of property, &c.; and the state monopolies cover opium and salt. In 1905 a loan of $600,000 was floated in Germany for additions to the navy. The growth of receipts and expenditures is shown in the following table:

The revenues of 1896 were only $1,128,714.

The foreign debt began with a small loan of £1,200,000 in London in 1822, and another of £1,500,000 in 1825 of which only £716,166 was placed. At the end of the war, these loans, and sums owing to Chile and Colombia, raised the foreign debt to £4,000,000. In
in the north of Peru, and at Cuzco, Ollantay-tambo and Huilafaque between Huaraz and Tiahuanaco. These works appear to have been erected by powerful sovereigns with unlimited command of labour, possibly with the object of giving employment to subjugated people, while feeding the vanity or pleasing the taste of the conqueror. Of their origin nothing is historically known. It is probable, however, that the settlement of the Cuzco valley and district by the Incas or "people of the sun" took place some 300 years before Pizarro landed in Peru. The conquering tribe or tribes had made their way to the sierra from the plains, and found themselves a new land sheltered from attack amidst the lofty mountains that hem in the valley of Cuzco and the vast lake basin of Titicaca, situated 12,000 ft. above the sea level. The first historical records show us these people already possessed of a considerable civilization, and speaking two allied languages, Aymara and Quechua. The expansion of the Incas and the formation of the Peruvian Empire was of modern growth at the time of the Spanish conquest, and dated from the victories of Pachacutic Inca who lived about a century before Huayna Capac, the Great Inca, whose death took place in 1532, the year before Pizarro first appeared on the coast. His conquest of the Inca Empire extended from the river Mantaro north of the Inca to the river Maule in the south of Chile. The Incas had an elaborate system of state-worship, with a ritual, and frequently recurring festivals. History and tradition were preserved by the bards, and dramas were enacted before the sovereign and his court. Roads with post-houses at intervals were made over the wildest mountain-ranges and the bleakest deserts for hundreds of miles. A well-considered system of land-tenure and of colonization provided for the wants of all classes of the people. The administrative details of government were minutely and carefully organized, and accurate statistics were kept by means of the "quipus" or system of knots. The edifices displayed marvellous building skill, and their workmanship is unsurpassed. The world has nothing to show, in the way of stone-cutting and fitting, to equal the skill and accuracy displayed in the Inca structures of Cuzco. As workers in metals and as potters they displayed infinite variety of design, while as cultivators and engineers they excelled their European conquerors. (For illustrations see America, Plate V.)

The story of the conquest has been told by Prescott and helpful, who give ample references to original authorities; it will be sufficient here to enumerate the dates of the leading events. On the 1oth of March 1526 the contract for the conquest of Peru was signed by Pedro de Pizarro, Diego de Almagro and Hernando de Luque, Gaspar de Espinosa, and Francisco de Lucar, and on 15th March Pizarro, after enduring fearful hardships, first reached the coast of Peru at Tumbes. In the following year he went to Spain, and on the 26th of July 1529 the capitulation with the Crown for the conquest of Peru was executed. Pizarro sailed from San Lucar with his brothers in January 1530, and landed at Tumbes in 1531. The civil war between Huascar and Atahualpa, the sons of Huayna Capac, had been fought out in the meanwhile, and the victorious Atahualpa was at Cajamarca on his way from Quito to Cuzco. On the 15th of November 1532 Pizarro with his little army, made his way to Cajamarca, where he received Atahualpa with friendly welcome from the Inca, whom he treacherously seized and made prisoner. He had with him only 183 men. In February 1533 his colleague Almagro arrived with reinforcements. The murder of the Inca Atahualpa was perpetrated on the 29th of August 1533, and on the 15th of November Pizarro entered Cuzco. He allowed the rightful heir to the empire, Manco, the legitimate son of Huayna Capac, to be solemnly crowned on the 24th of March 1534. Almagro then undertook an expedition to Chile, and Pizarro founded the city of Lima on the 18th of January 1535. In the following year the Incas made a brave attempt to expel the invaders, and closely besieged the Spaniards in Cuzco during February and March. Almagro, returning from Chile, raised the siege on the 18th of April 1537. Immediately afterwards a dispute arose between the brothers, Francisco, Juan and Gonzalo Pizarro and Almagro.
as to the limits of their respective jurisdictions. An interview took place at Mala, on the sea-coast, on the 15th of November 1537, which led to no result, and Almagro was finally defeated in the battle of Las Salinas near Cuzco on the 26th of April 1538. His execution followed. His adherents recognized his young half-caste son, a gallant and noble youth generally known as Almagro the Lad, as his successor. Bitterly discontented, they conspired at Lima and assassinated Francisco Pizarro on the 26th of June 1541. Meanwhile Vaca de Castro had been sent out as governor of Peru by Charles V., and on hearing of the murder of Pizarro he assumed the government of the country.

On the 16th of September 1542 he defeated the army of Almagro in the battle of Chupas near Guamaniga, and the boy was beheaded at Cuzco.

Charles V. enacted the code known as the "New Laws" in 1542. "Encomiendas," or grants of estates on which the inhabitants were bound to pay tribute and give personal service to the grantee, were to pass to the Crown on the death of the actual holder; a fixed sum was to be assessed as tribute; and forced personal service was forbidden. Blasco Nuñez de Velasquez was sent out, as first viceroy of Peru, to enforce the "New Laws." Their promulgation aroused a storm among the conquerors. Gonzalo Pizarro rose in rebellion, and entered Lima on the 28th of October 1544. The viceroy fled to Quito, but was followed, defeated and killed at the battle of Anauquito on the 18th of January 1546. The "New Laws" were weakly revoked, and Pedro de la Gasca, as first president of the Audiencia (court of justice) of Peru, was sent out to restore order. He arrived in 1547, and on the 8th of April 1548 he routed the followers of Gonzalo Pizarro on the plain of Sacahuaman near Cuzco. Gonzalo was executed on the field. La Gasca made a redistribution of "encomiendas" to the loyal conquerors, which caused great discontent, and left Peru before his scheme was made public in January 1550. On the 23rd of September 1551 Don Antonio de Mendoza arrived as second viceroy, but he died at Lima in the following July. The country was then ruled by the judges of the Audiencia, and a formidable insurrection broke out, headed by Francisco Hernandez Giron, with the object of maintaining the right of the conquerors to exact forced service from the Indians. In May 1554 Giron defeated the army of the judges at Chuplinga, but he was hopelessly routed at Pucara on the 11th of October 1554, captured, and on the 7th of December executed at Lima. Don Antonio de Mendoza was appointed governor of Lima as third viceroy of Peru on the 6th of July 1555, and ruled with an iron hand for six years. All the leaders in former disturbances were sent to Spain. Corregidors, or governors of districts, were ordered to try summarily and execute every turbulent person within their jurisdictions. All unemployed persons were sent on distant expeditions, and moderate "encomiendas" were granted to a few deserving officers. At the same time the viceroy wisely came to an agreement with Sayri Tupac, the son and successor of the Inca Manco, and granted him a pension. He took great care to supply the natives with priests of good conduct, and promoted measures for the establishment of schools and the foundation of towns in the different provinces. In the colonization of new territories, European domestic animals were introduced. The next viceroy was the Conde de Nieva (1561-1564). His successor, the licentiate Lope Garcia de Castro, who only had the title of governor, ruled from 1564 to 1566. From this time there was a succession of viceroys until 1824. The viceroy was chief magistrates, but in legal matters they had to consult the Audiencia of judges, in finance the Tribunal de Cuentas, in other branches of administration the Juntas de Gobierno and de Guerra.

Don Francisco de Toledo, the second son of the count of Oropesa, entered Lima as viceroy on the 26th of November 1566. Pecking that the little court of the Inca Tupac Amaru (who had succeeded his brother Sayri Tupac) might become a focus of rebellion, he seized the young prince, and unjustly beheaded the last of the Incas in the square of Cuzco in the year 1571. After a minute personal inspection of every province in Peru, he, with the experienced aid of the learned Polo de Ondegardo and the judge of Matienza, established the system under which the native population of Peru was ruled for the two succeeding centuries. His "Libro de Tasos" fixed the tribute to be paid by the Indians, exempting all men under eighteen and over fifty. He found it necessary, in order to secure efficient government, to revert in some measure to the system of the Incas. The people were to be directly governed by their native chiefs, whose duty was to collect the tribute and exercise magisterial functions. The chiefs or "curacas" had subordinate native officials under them called "pichca-pachacas" over 500 men, and "pachacas" over 100 men. The office of curaca or cacique was made hereditary, and its possessor enjoyed several privileges. Many curacas were descended from the imperial family of the Incas, or from great nobles of the Incarcal court. In addition to the tribute, which was in accordance with native usage, there was the "mita," or forced labour in mines, farms and manufactories. Toledo enacted that one-seventh of the male population of a village should be subject to conscription for this service, but they were to be paid, and were not to be taken beyond a specified distance from their homes.

The Spanish kings and viceroys desired to protect the people from tyranny, but they were unable to prevent the rapacity and lawlessness of distant officials and the country was depopulated by the illegal methods of enforcing the mita. Toledo was succeeded in 1581 by Don Martin Henriquez, who died at Lima two years afterwards. The Spanish colonies suffered from the strict system of monopoly and protection, which was only slightly relaxed by the later Bourbon kings, and from the arbitrary proceedings of the Inquisition. Between 1581 and 1766 as many as fifty-nine heretics were burned at Lima, and there were twenty-nine "autos"; but the Inquisition affected Europeans rather than natives, for the Indians, as catechumens, were exempted from its terrors. The curacas sorrowfully watched the gradual extinction of their people by the operation of the mita, protesting from time to time against the exactions and cruelty of the Spaniards. At length a descendant of the Incas, who assumed the name of Tupac Amaru, rose in rebellion in 1780. The insurrection lasted until July 1783, and cruel executions followed its suppression. This was the last effort of the Indians to throw off the Spanish yoke and the rising was by no means general. The army which overthrew Tupac Amaru consisted exclusively of loyal colonists, and the rebellion was purely anti-Spanish, and had no support from the Spanish population. The movement for independence, which slowly gained force during the opening decade of the 19th century, did not actually become serious until the conquest of Spain by the French in 1807-1808. The Creoles (Ciales) or American-born Spaniards had for long been aggrieved at being shut out from all important official positions, and at the restrictions placed upon their trade, but the bulk of the Creole population was not disloyal.

Peru was the centre of Spanish power, and the viceroy had his military strength concentrated at Lima. Consequently the insurgents of 1810 and 1811 on the northern frontier of Chile and Buenos Aires, were the first to declare themselves independent, in 1816 and 1817. But the destruction of the viceroy's power was essential to their continued independent existence. The conquest of the Peruvian coast must always depend on the command of the sea. A fleet of armed ships was fitted out at Valparaiso in Chile, under the command of Lord Cochrane (afterwards earl of Dundonald) and officered by Englishmen. It convoyed an army of Argentine troops, with some Chileans, under the command of the Argentine general, San Martin, which landed on the coast of Peru in September 1820. San Martin was enthusiastically received, and the independence of Peru was proclaimed at Lima after the viceroy had withdrawn. July 25th, 1820. The 26th of September 1822 San Martin resigned the protectorate, with which he had been invested, and on the same day the first
The congress of Peru became the sovereign power of the state. After a short period of government by a committee of three, the congress elected Don José de la Riva Agüero to be first president of Peru on the 28th of February 1823. He displayed great energy in facing the difficulties of a turbulent situation, but was unsuccessful. The aid of the Colombians under Simón Bolívar was sought, and Agüero was deposed.

Bolívar arrived at Lima on the 1st of September 1823, and began to organize an army to attack the Spanish viceroy in the interior. On the 6th of August 1824 the cavalry action of Junín was fought with the Spanish forces under the command of a French adventurer, General Canterac, near the shore of the lake of Chinchaycocha. It was won by a gallant charge of the Peruvians under Captain Suarez at the critical moment. Soon afterwards Bolívar left the army to proceed to the coast, and the final battle of Ayacucho (Dec. 9, 1824) was fought by his second in command, General Sucre. The victory and all his officers were taken prisoners, and the Spanish power in Peru came to an end.

General Bolívar ruled Peru with dictatorial powers for more than a year, and though there were cabals against him there can be little doubt of his popularity. He was summoned back to Colombia when he had been absent for five years and, in spite of protests late on the country on the 3rd of September 1826, followed by all the Colombian troops in March 1827.

General José de Lamar, who commanded the Peruvians at Ayacucho, was elected president of Peru on the 24th of August 1827, but was deposed, after waging a brief but disastrous war with Colombia on the 7th of June 1829. General Agustín Gamarra, who had been in the Spanish service, and was chief of the staff in the patriot army at Ayacucho, was elected third president on the 31st of August 1829.

For fifteen years, from 1829 to 1844, Peru was painfully feeling her way to a right use of independence. The officers who fought at Ayacucho, and to whom the country felt natural gratitude, were all-powerful, and they had not learned to settle political differences in any other way than by the sword. Three men, during that period of probation, won a prominent place in their country's history, Generals Agustín Gamarra, Felipé Santiago Salaverry, and Andrés Santa Cruz. Gamarra, born at Cuzco in 1785, never accommodated himself to constitutional usages; but he attached to himself many loyal and devoted friends, and, with all his faults he loved his country and sought its welfare according to his lights. Salaverry was a very different character. Born at Lima in 1806, of pure Basque descent, he joined the patriot army before he was fifteen and displayed his audacity and bravery in many battles. Feeling strongly the necessity that Peru had for repose, and the guilt of civil dissension, he wrote patriotic poems which became very popular. Yet he too seized the supreme power, and perished by an iniquitous sentence on the 18th of February 1832.

Andrés Santa Cruz was an Indian statesman. His mother was a lady of high rank, of the family of the Incas, and he was very proud of his descent. Unsuccessful as a general in the field, he nevertheless possessed remarkable administrative ability and for nearly three years (1836-1839) realized his lifelong dream of a Peru-Bolivian confederation. But the strong-handed intervention of Chile on the ground of assistance rendered to rebels, but really through jealousy of the confederation, ended in the defeat and overthrow of Santa Cruz, and the separation of Bolivia from Peru. But Peruvian history is not confined to the hostilities of these military rulers. Three constitutions were framed—in 1828, 1833 and 1839. Lawyers and orators are never wanting in Spanish-American states, and revolution succeeded revolution in one continuous struggle for the spoils

1 The romance of his life has been admirably written by William H. Biddle (1st ed., Lima, 1853; 2nd ed., Buenos Aires, 1867).
2 The succession of presidents and supreme chiefs of Peru from 1829 to 1844 was as follows: 1829-1833, Agustín Gamarra; 1834-1835, Luis José Orbe; 1835-1836, Felipe Santiago Salaverry; 1836-1839, Andrés Santa Cruz; 1839-1841, Agustín Gamarra; 1841-1844, Manuel Menéndez.
3 Of office. An exception must be made of the administration of General Ramón Castilla, who restored peace to Peru, and showed himself to be an honest and very capable ruler. He was elected constitutional president on the 20th of April 1845. Ten years of peace and increasing prosperity followed. In 1849 the regular payment of the interest of the public debt was commenced, steam communication was established along the Pacific coast, and a railroad was made from Lima to Callao. After a regular term of office of six years of peace and moral and material progress Castilla resigned, and General José Echenique was elected president. But the proceedings of Echenique's government in connexion with the consolidation of the internal debt were disapproved by the nation, and, after hostilities which lasted for six months, Castilla returned to power in January 1855. From December 1856 to March 1858 he had to contend with and subdue a local insurrection headed by General Agostino Vivanco, but, with these two exceptions, there was peace in Peru from 1844 to 1879, a period of thirty-five years. Castilla retired at the end of his term of office in 1862, and died in 1868. On the 2nd of August 1868 Colonel Juan Balta was elected president. With the vast sum raised from guano and nitrate deposits President Balta commenced the execution of public works, principally railroads on a gigantic scale. His period of office was signalized by the opening of an international exhibition at Lima. He was succeeded (Aug. 2, 1872) by Don Manuel Pardo (d. 1878), an honest and enlightened statesman, who did all in his power to retrieve the country from the financial difficulty into which it had been brought by the reckless policy of his predecessor, but the conditions were not capable of solution. He regulated the Chinese immigration to the coast-valleys, which from 1860 to 1872 had amounted to 58,606. He promoted education, and encouraged literature. On the 2nd of August 1876 General Mariano Ignacio Prado was elected.

3 (C. R. M.; X.)

On the 5th of April 1879 the republic of Chile declared war upon Peru, on the alleged pretext that Peru had signed an offensive treaty, directed against Chile, with Bolivia, War with a country with which Chile had a dispute; but the Chile, 1879-1883, publication of the text of this treaty made known the fact that it was strictly defensive and contained no just cause of war. The true object of Chile was the conquest of the rich Peruvian province of Tarapacá, the appropriation of its valuable guano and nitrate deposits, and the spoliation of the rest of the Peruvian coast. The military events of the war, calamitous for Peru, are dealt with in the article Chile-Peruvian War. Suffice it here to note that, after the crushing defeat of the Peruvian forces at Arica (June 7, 1880) Señor Nicolás de Piérola assumed dictatorial powers with General Andrés Cáceres as commander-in-chief, but the defeats at Chorrillos (Jan. 13, 1881) and Miraflores (Jan. 15) proved the Chilean superiority, and put Lima at their mercy though desultory fighting was maintained by the remnants of the Peruvian army in the interior, under direction of General Cáceres. An attempt was made to constitute a government with Señor Calderon as president of the republic and General Cáceres as first vice-president. The negotiations between this nominal administration and the Chilean authorities for a treaty of peace proved futile, the Chilean occupation of Lima and the Peruvian seaboard continuing uninterrupted until 1883. In that year Admiral Lynch, who had replaced General Baquedano in command of the Chilean forces after the taking of Lima, sent an expedition against the Peruvians under General Cáceres, and defeated the latter in the month of August. The Chilean authorities now began preparations for the evacuation of Lima, and to enable this measure to be effected a Peruvian administration was organized with the support of the Chileans. General Iglesias was nominated to the office of president of the republic, and in October 1883 a treaty of peace, known as the treaty of Ancón, between Peru and Chile was signed. The Chilean army of occupation was withdrawn from Lima on the 22nd of October 1893, but a strong force was maintained at Chorrillos until July 1884, when the terms of the treaty were finally approved. The
principal conditions imposed by Chile were the absolute cession by Peru of the province of Tarapacá, and the occupation for a period of ten years of the territories of Tacna and Arica. The ownership of these districts was to be decided by a popular vote of the inhabitants of Tacna and Arica at the expiration of the period named. A further condition was enacted that an indemnity of 10,000,000 soles was to be paid by the country finally remaining in possession—a sum equal to about $1,000,000 to-day. The Peruvians in the interior refused to recognize President Iglesias, and at once began active operations to overthrow his authority on the final departure of the Chilean troops.

Affairs continued in this unsettled state until the middle of 1885. Caceres meanwhile steadily gaining many adherents to his side of the quarrel. In the latter part of 1885 President Iglesias abdicated.

Under the guidance of General Caceres a junta was then formed to carry on the government until an election for the presidency should be held and the senate and chamber of deputies constituted. In the following year (1886) General Caceres was elected president of the republic for the usual term of four years. The task assumed by the new president was no sinecure. The country had been thrown into absolute confusion from a political and administrative point of view, but gradually order was restored, and personal conditions were reconstituted throughout the republic. The four years of office for which General Caceres was elected passed in uneventful fashion, and in 1890 Señor Morales Bermudez was nominated to the presidency, with Señor Solar and Señor Borgoño as first and second vice-presidents. Matters continued without alteration from the normal course until 1894, and in that year Bermudez died suddenly a few months before the expiration of the period for which he had been chosen as president. General Caceres secured the nomination of the vice-president Borgoño as chief of the executive for the unexpired portion of the term of the late president Bermudez. This action was unconstitutional, and was bitterly resented by the vice-president Solar, who by right should have succeeded to the office. Armed resistance to the authority of Borgoño was immediately organized in the south of Peru, the movement being supported by Señores Nicolas de Pierola, Billinghurst, Durand and a number of influential Peruvians. In the month of August 1894 General Caceres was again elected to fill the office of president, but the revolutionary movement rapidly gained ground. President Caceres adopted energetic measures to suppress the outbreak: his efforts, however, proved unavailing, the close of 1894 finds the country districts in the power of the rebels and the authority of the legal government confined to Lima and other cities held by strong garrisons. Early in March 1895 General Caceres was surrounded near the outskirt of Lima, and on the 17th, 18th and 19th of March severe fighting took place, ending in the defeat of the troops under General Caceres. A suspension of hostilities was then brought about by the efforts of H.B.M. consul. The loss on both sides to the struggle during these two days was 2800 killed and wounded. President Caceres, finding his cause was lost, left the country, a provisional government under Señor Candamo assuming the direction of public affairs.

On the 8th of September 1895 Señor Pierola was declared president of the republic for the following four years. The Peruvians were now heartily tired of revolutionary disturbances, and an insurrectionary outbreak in the district of Iquitos met with small sympathy, and was speedily crushed. In 1896 a reform of the electoral law was sanctioned. By the provisions of this act an electoral committee was constituted, composed of nine members, two of these nominated by the senate, two by the chamber of deputies, four by the supreme court, and one by the president with the consent of his ministers. To this committee was entrusted the task of the examination of all election returns, and of the proclamation of the names of successful candidates for seats in congress. Another reform brought about by Pierola was a measure introduced and sanctioned in 1897 for a modification of the marriage laws. Under the new act marriages of non-Catholics solemnized by diplomatic or consular officers or by ministers of dissenting churches, if properly registered, are valid, and those solemnized before the passing of this act were to be valid if registered before the end of 1899. Revolutionary troubles again disturbed the country in 1899, when the presidency of Señor Pierola was drawing to a close. In consequence of dissensions amongst the members of the election committee constituted by the act of 1896, the president ordered the suppression of this body. A group of malcontents under the leadership of one Durand, a man who had been prominent in the revolution against General Caceres in 1894-95, conspired against the authorities and raised several armed bands, known locally as montaneras. Some skirmishes occurred between these insurgents and the government troops, the latter generally obtaining the advantage in these encounters.

In September 1899 President Pierola vacated the presidency in favour of Señor Romana, who had been elected to the office as a popular candidate and without the exercise of any undue official influence. President Romana was educated at Stonyhurst in England, and was a civil engineer by profession. The principal political problem before the government of Peru was the ownership of the territories of Tacna and Arica. The period of ten years agreed upon for the Chilean occupation of these provinces expired in 1894. At that date the peace of Peru was so seriously disturbed by internal troubles that the government was quite unable to take active steps to bring about any solution of the matter. After 1894 negotiations between the two governments were attempted from time to time, but without any satisfactory results. The question hinged to a great extent on the qualification necessary for the inhabitants to vote, in the event of a plebiscite being called to decide whether Chilean ownership was to be finally established or the provinces were to revert to Peruvian sovereignty. Peru proposed that only Peruvian residents should be entitled to take part in a popular vote; Chile rejected this proposition, on the ground that all residents in the territories in question should have a voice in the final decision. The agreement between Chile and Bolivia, by which the disputed provinces were to be handed over to the latter country if Chilean possession was recognized, was also a stumbling-block, a strong feeling existed among Peruvians against this proceeding. It was not so much the value of Tacna and Arica that put difficulties in the way of a settlement as the fact that the national pride of the Peruvians ill brooked the idea of permanently losing all claim to this section of country. The money, about $1,000,000, could probably have been obtained to indemnify Chile if occasion for it arose.

The proposition of the delimitation of the frontier between Peru and the neighbouring republics of Ecuador, Colombia, and Brazil also cropped up at intervals. A treaty was signed with Brazil 1876, by which certain physical features were accepted by both countries as the basis for the boundary. In the case of Ecuador and Colombia a dispute arose in 1894 concerning the ownership of large tracts of uninhabited country in the vicinity of the headwaters of the Amazon and its tributaries. An agreement was proposed between Peru and Ecuador in connexion with the limits of the respective republics, but difficulties were created to prevent this proposal from becoming an accomplished fact by the pretensions put forward by Colombia. The latter state claimed sovereignty over the Napo and Marañon rivers on the grounds of the ecclesiastical jurisdiction exercised over this section of territory during the period of Spanish dominion, the government of Colombia asserting that these ecclesiastical rights to which Colombia became entitled after her separation from the Spanish crown carried also the right of absolute ownership. In a treaty signed by the three interested states in 1895 a compromise was effected by which Colombia withdrew a part of the claim advanced, and it was agreed that any further differences arising out of this frontier question should be submitted to the arbitration of the Spanish crown. The later development of the boundary question is dealt with at the outset of this article.
In 1995 the value of the factory products was $1,703,417 (27-3% more than in 1990). Petroleum was found in 1834 and was chartered as a city in 1867.

PERUGIA (anc. Perusia), a city and archiepiscopal see of Italy, the capital of the province of Perugia (which forms the entire *compartimento* of Umbria) situated 1444 ft. above sea-level. Pop. (1900), 22,321 (town); 65,527 (commune). The town is finely situated upon a group of hills nearly 1000 ft. above the valley of the Tiber. Its outline is very irregular; from the centre of the town, at the junction of several ridges, parts of it extend for a considerable distance along their summits, being divided from one another by deep valleys. This is the extent enclosed by the medieval walls; within them are considerable remains of the lofty terrace walls of the Etruscan period. The so-called Arco di Augusto is a town gate with a Decorated superstructure, perhaps of the Etruscan period, bearing the inscription *Augusta Perusia*; above this again is a Renaissance loggia. The superstructure of a similar gate (Porta Marzia), which was removed in 1540 to make way for the citadel, but is depicted in a fresco by Benedetto Bonfigli (between 1461 and 1477). The second Arco di Augusto was re-erected in the subtraction walls of the citadel.

It bears the inscription *Colonia Vibia Augusta Perusia*, so that the town must have become a colony in the reign of the emperor C. Vibia Tronianus Gallus (A.D. 251–252), who was a native of it. Four other gates of the Etruscan period can still be traced (F. Noack in *Römische Mitteilungen*, 1897, 166 sqq.). In the garden of the church of S. Elisabetta was found in 1876 a fine mosaic in black on a white ground representing Orpheus in the midst of the beasts (*Notizie degli scavi*, 1876, 181; 1877, 599).

The citadel was erected by Pope Paul III. in 1540–1546, after the plans of Antonio da Sangallo the younger, and demolished in 1860 (see Bacile di Castiglia in *L'Arte*, 1903, 347). The Piazza del Duomo is at the north of the Corso. On one side stands the cathedral of San Lorenzo, a Gothic structure of the 14th and 15th centuries, in the plan of a Latin cross, with nave and aisles of equal height; on the other the Palazzo del Municipio, presenting two fine Gothic façades, of the 14th century (though the building was not completed till 1443), with the figures of the Perugian griffin and the Guelph lion above the outside stair; and in the centre the marble fountain constructed in 1277–1280 by Arnolfo di Cambio, and adorned with statues and statuettes by Niccolò and Giovanni Pisano. The cathedral contains the burial-place of Urban IV. and Martin IV.—the remains of Innocent III. were removed to Rome in 1892 and placed in the basilica of S. Giovanni in Laterano—and the Virgin's wedding-ring; and at the north-east corner is a sitting statue of Pope Julius III. by Vincenzo Danti, erected in 1555 by the people of Perugia in gratitude for the restoration of their civic privileges.

On the decoration of the Sala del Cambio, or old exchange, Perugino put forth the full force of his genius. Most of the movable paintings have since 1863 been collected in the Pinacoteca Vannucci, established in the Palazzo del Municipio; besides a considerable number of pieces by Perugino, there are specimens of Niccolò Alunno, Bonfigli, Pinturicchio, &c. A very interesting and important exhibition of Umbrian art was held here in 1905. The pictures, the medallions, the maiolica and porcelain, and embroiery from S. Francesco at Assisi, the vestments of Pope Benedict XI., and the majolica of Perugia and Deruta, a village 10 m. south, were especially noteworthy (see U. Gnoi, *L'Arte umbra alla mostra di Perugia*, Bergamo, 1908). The illuminated MSS. of the communal library, the cathedral and the church of S. Pietro, from the 7th century onwards, were also exhibited.

The formation of the Pinacoteca Vannucci has impaired the interest of several churches but in others it remains undiminished. San Domenico, a Gothic edifice originally designed by Giovanni Pisano but rebuilt in 1614, contains the monument of Pope Sixtus II. (attributed to Giovanni Piombo), and the Virgin's wedding-ring; and at the east front a Gothic window with stained glass by Fra Bartolommeo of Perugia (1441). San Pietro de' Cassigni (outside the Porta Romana) is a basilica
with nave and aisles, founded in the beginning of the 11th century by San Pietro Vincioi on the site of a building of the 6th century, and remarkable for its conspicuous spire, its ancient granite and marble columns, its walnut stall-work of 1533 by Stefano de’ Zambellì da Bergamo, and its numerous pictures (by Perugino, &c.). The oratory of S. Bernardino has an early Renaissance polychrome façade, richly sculptured, of 1457-1461, by Agostino d’Antonio di Duccio of Florence. S. Severo contains Raphael’s first independent fresco (1495), much damaged by restoration. The circular church of S. Angelo, with sixteen antique columns in the interior, probably dates from the middle of the 6th century. The university dates from 1307, and has faculties of law, science and medicine; it had 318 students in 1902-1903. It contains an important museum of Etruscan and Roman antiquities. Three miles to the S.S.E. the Etruscan necropolis of the ancient city was discovered in 1870. The large tomb of the Volumni (3rd century B.C.) hewn in the rock, with its carved cinerary urns, is interesting.

The ancient Perugia first appears in history as one of the twelve confederate cities of Etruria. It is first mentioned in the account of the war of 310 or 309 B.C. between the Etruscans and the Romans. It took, however, an important part in the rebellion of 295, and was reduced, with Vulsini and Arretium, to seek for peace in the following year. In 216 and 205 it assisted Rome in the Hannibal war, but afterwards it is not mentioned until 41-40 B.C., when L. Antonius took refuge there, and was reduced by Octavian after a long siege. A number of lead bullets used by soldiers have been found in and around the city (Corpus inscr. lat. xi. 1212). The city was burnt, we are told, with the exception of the temples of Vulcan and Juno —the massive Etruscan terrace-walls, naturally, can hardly have suffered at all—and the town, with the territory for a mile round, was allowed to be occupied by whoever chose. It must have been rebuilt almost at once, for several bases exist, inscribed Augusto sacr(um) Perusia restituit; but, as we have seen, it did not become a colony until A.D. 251-252. It is hardly mentioned except by the geographers until the middle of the 6th century, when it was captured by Totila after a long siege. In the Lombard period it is spoken of as one of the principal cities of Tuscia. In the 9th century, with the consent of Charlemagne the Great and Louis the Pious, it passed under the popes; but for many centuries the city continued to maintain an independent life, warring against many of the neighbouring lands and cities— Foligno, Assisi, Spoleto, Montepulciano, &c. It remained true for the most part to the Guelf party, and on occasions the popes found asylum within its walls, and it was the meeting-place of the conclaves which elected Honorius II. (1124), Honorius IV. (1285), Celestine V. (1294), and Clement V. (1305). But Perugia had no mind simply to subservie the papal interests. At the time of Rienzi’s unfortunate enterprise it sent ten ambassadors to pay him honour; and, when papal legates sought to coerce it by foreign soldiers, or to exact contributions, they met with vigorous resistance. In the 15th century power was at last concentrated in the Baglioni family, who, though they had no legal position, defied all other authority. Gian Paolo Baglioni was lured to Rome in 1520 and beheaded by the Emperor. A feud then arose between the Baglioni and the Rucellai family, and was disputed by Pier Luigi Farnese, and the city, captured and plundered by his soldiery, was deprived of its privileges. The citadel was begun six years later “ad coerendam Perusinorum audaciam.” In 1707 Perugia was occupied by the French; in 1832, 1838 and 1854 it was visited by earthquakes; in May 1849 it was seized by the Austrians; and, after a futile insurrection in 1859, it was finally united, along with the rest of Umbria, to Piedmont, in 1860.

PERUGINO, PIETRO (1446-1524), whose correct family name was VANNUCCI, Italian painter, was born in 1446 at Città della Pieve in Umbria, and belongs to the Umbrian school of painting. The name of Perugino came to him from Perugia, the chief city of the neighbourhood. Pietro was one of several children born to Cristoforo Vannucci, a member of a respectable family settled at Città della Pieve. Though respectable, they seem to have been poor, or else, for some reason or other, to have left Pietro unsecured for the opening of his career. Before he had completed his ninth year the boy was articled to a master, a painter at Perugia. Who this may have been is very uncertain; the painter is spoken of as wholly mediocre, but sympathetic for the great things in his art. Benedetto Bonfigli is generally surmised; if he is rejected as being above mediocrity, either Florenco di Lorenzo or Niccolò da Foligno may possibly have been the man. Pietro painted a little at Arezzo; thence he went to the headquarters of art, Florence, and frequented the famous Brancacci Chapel in the church of the Carmine. It appears to be sufficiently established that he studied in the atelier of Andrea del Verrocchio, where Leonardo da Vinci was also a pupil. He may have learned perspective, in which he particularly excelled for that period of art, from Pietro de' Franceschi. The date of this first Florentine sojourn is by no means settled; some authorities incline to make it as early as 1470, while others, with perhaps better reason, postpone it till 1479. Pietro at this time was extremely poor; he had no bed, but slept on a chest for many months, and, bent upon making his way, resolutely denied himself every creature comfort.

Gradually Perugino rose into notice, and became famous not only throughout Italy but even beyond. He was one of the earliest Italian painters to practise oil-painting, in which he excelled a depth and smoothness of tint, which elicited much remark; and in perspective he applied the novel rule of two centres of vision. Some of his early works were extensive frescoes for the Ingesati fathers in their convent, which was destroyed not many years afterwards in the course of the siege of Florence; he produced for them also many cartoons, which they executed with brilliant effect in stained glass. Though greedy for gain, his integrity was proof against temptation; and an amusing anecdote has survived of how the prior of the Ingesati doled out to him the costly colour of ultramarine, and how Perugino, constantly washing his brushes, obtained a surreptitious hoard of the pigment, which he finally restored to the prior to shame his stingy suspiciousness. A good specimen of his early style in tempera is the circular picture in the Louvre of the "Virgin and Child enthroned between Saints." Perugino returned from Florence to Perugia, and thence, towards 1485, he went to Rome. This was the period of his part in the Sixtine Chapel which is now immortalized by Michelangelo’s "Last Judgment," was assigned to him by the pope; he covered it with frescoes of the "Assumption," the "Nativity," and "Moses in the Bulrushes." These works were ruthlessly destroyed to make a space for his successor's more colossal genius, but other works by Perugino still remain in the Sixtine Chapel; "Moses and Zipporah" (often attributed to Signorelli), the "Baptism of Christ," and "Christ giving the Keys to Peter." Pinturicchio accompanied the great Umbrian to Rome, and was made his partner, receiving a third of the profits; he may probably have done some of the Zipporah subject.

Perugino left Rome after the completion of the Sixtine paintings in 1486, and in the autumn of that year he was in Florence. Here he figures by no means advantageously in a criminal court. In July 1487 he and another Perugian painter named Aulista di Angelo were convicted, on their own confession, of having in December waylaid with staves some one (the name does not appear) in the street near S. Pietro Maggiore. Perugino limited himself, in intention, to assault and battery, but Aulista had made up his mind for murder. The minor and more illustrious culprit was fined ten gold florins, and the major one exiled for life.

Between 1486 and 1499 Perugino resided chiefly in Florence, making the journey thither and several to Perugia. He was in many other parts of Italy from time to time. He had a regular shop in Florence, received a great number of commissions, and continued developing his practice as an oil-painter, his
system of superposed layers of colour being essentially the same as that of the Van Eycks. One of his most celebrated pictures, the “Pieta” in the Pitti Gallery, belongs to the year 1495. From about 1498 he became increasingly keen after money, frequently repeating his groups from picture to picture, and leaving much of his work to journeymen. In 1499 the gild of the cambio (money-changers or bankers) of Perugia asked him to undertake the decoration of their audience-hall, and he accepted the invitation. This extensive scheme of work, which may have been finished within the year 1500, comprised the painting of the vault with the seven planets and the signs of the zodiac (Perugino painting the designs and his pupils most probably the executive work) and the representation on the walls of two sacred subjects—the “Nativity” and “Transfiguration”—the Eternal Father, the four virtues of Justice, Prudence, Temperance and Fortitude, Cato as the emblem of wisdom, and (in life size) numerous figures of classic worthies, prophets and sibyls. On the mid-pilaster of the hall Perugino placed his own portrait in bust-form. It is probable that Raphael, who in boyhood, towards 1496, had been placed by his uncles under the tuition of Perugino, bore a hand in the work of the vaulting. It may have been about this time (though some accounts date the Verta, in a few years, with the Sistine Chapel). The painting of a beautiful wife, the object of his fond affection; he loved to see her handsomely dressed, and would often deck her out with his own hands. He was made one of the priors of Perugia in 1501.

While Perugino, though by no means stationary or inoperative as an executive artist, was working contentedly upon the old lines and carrying out the ancient conceptions, a mighty wave of new art flooded Florence with its rush and Italy with its humour. Michelangelo, twenty-five years of age in 1500, following after and distancing Leonardo da Vinci, was opening men’s eyes and minds to possibilities of achievement as yet unsurpassed. Vannucci in Perugia heard Buonarroti bruiting abroad, and was impatient to see with his own eyes what the stir was all about. In 1504 he allowed his apprentices and assistants to disperse, and returned to Florence. Though not openly detracting, he viewed with jealousy and some grudging the advances made by Michelangelo; and Michelangelo on his part replied, with the intolerance which pertains to superiority, to the faint praise or covert dispraise of his senior and junior in the art. On one occasion, in company, he told Perugino to his face that he was a “banger in art” (gaffo nell’arte). Vannucci brought, with equal indiscretion and ill success, an action for defamation of character. Put on his mettle by this mortifying transaction, he determined to show what he could do, and produced the chefd’œuvre of the “Madonna and Saints” for the Certosa of Pavia. The constituent parts of this noble work have now been subdued. The only portion which remains in the Certosa is a figure of God the Father with cherubim. An “Annunciation” has disappeared from cognisance; three compartments—the Virgin adorning the infant Christ, St Michael, and St Raphael with Tobias—are among the choice treasures of the National Gallery, London. The current story that Raphael bore a hand in the work is not likely to be true. This was succeeded in 1505 by an “Assumption,” in the Cappelle dei Pazzi, in the Uffizi; in 1506 the “Assumption” in the Scuola di San Domenico. The painting may have been executed chief by a pupil, and was at any rate a failure: it was much decried; Perugino lost his scholars; and towards 1506 he once more and finally abandoned Florence, going to Perugia, and thence in a year or two to Rome.

Pope Julius II. had summoned Perugino to paint the Stanza in the Vatican, now called that of the Incendio del Borgo; but he soon preferred a younger competitor, that very Raphael who had been trained by the aged master of Perugia; and Vannucci, after painting the ceiling with figures of God the Father in different glories, in five medallion-subjects, found his occupation gone; he retired from Rome, and was once more in Perugia from 1512. Among his latest works are the “Kiss of Judas,” 1513, and the “Burial of the S. Agostino in Florence,” 1517. The painting of his parts is now dispersed in various galleries.

Perugino’s last frescoes were painted for the monastery of S. Agnese in Perugia, and in 1522 for the church of Castello di Fortignano hard by. Both series have disappeared from their places, the second being now in the Victoria and Albert Museum. He was still at Fontignano in 1524 when the plague broke out, and he died. He was buried in unconsecrated ground in a field, the precise spot now unknown. The reason for so obscure and unwonted a mode of burial has been discussed, and religious scepticism on the painter’s own part has been assigned as the cause; the fact, however, appears to be that, on the sudden and widespread outbreak of the plague, the panic-struck local authorities ordained that all victims of the disorder should be at once interred without any waiting for religious rites. This leads us to speak of Perugino’s opinions on religion. Vasari is our chief, but not our sole, authority for saying that Vannucci had very little religion, and was an open and obdurate disbeliever in the immortality of the soul. For a reader of the present day it is easier than it was for Vasari to suppose that Perugino may have been a materialist, and yet just as good and laudable a man as his orthodox Catholic neighbours or brother-artists; still there is a strong discrepancy between the quality of his art, in which all is throughout Christian, Catholic, devotional, and pious, and the contemptuous, heretical, and irreverent dis- crepancy of the doctrine of immortality. It is difficult to reconcile this discrepancy, and certainly not a little difficult also to suppose that Vasari was totally mistaken in his assertion; he was born twenty years before Perugino’s death, and must have talked with scores of people to whom the Umbrian painter had been well known. We have to remark that Perugino in 1494 painted his own portrait, now in the Uffizi Gallery of Florence, and into this he introduced a scroll lettered “Timete Deum.” That an open disbeliever should inscribe himself with “Timete Deum” seems odd. The portrait in question shows a plump face, with small black eyes, a short but well-cut nose, and sensuous lips; the neck is thick, the hair bunched and frizzed like a general air imposing. The later portrait in the Cambio of Perugia shows the same face with traces of added years. Perugino did possessed of considerable property, leaving three sons.

Among the very numerous works of Perugino a few not already named require mention. Towards 1496 he painted the “Crucifixion,” in S. Maria Maddalena dei Pazzi, Florence. The attribution to hira of the picture of the marriage of Joseph and the Virgin Mary (the “Sposilizio”) now in the museum of Castello, is regarded indisputably as the original, to a great extent, of the still more famous “Sposilizio” which was painted by Raphael in 1504, and formed the portion of the “Last Supper” of the Palace of the Council in Milan, which is now questioned, and it is assigned to Lo Spagna. A vastly finer work of Perugino’s is the “Ascension of Christ,” which, painted a little earlier for S. Pietro of Perugia, has for years past been in the Loggia di Memmo; it is now dispersed in the churches of S. Domenico and in some other galleries. In the chapel of the Disciplinati of Città della Pieve is an “Adoration of the Magi,” a square of 21 ft. containing almost thirty life-sized figures; this was executed, with scarcely credible celerity, from the 1st to the 25th of March (or thereabouts) in 1505, and must no doubt be in great part the work of Vannucci’s pupils. In 1507, when the master’s work had for years been in a course of decline and his performances were generally to be produced, nevertheless, one of his best pictures—the “Virgin between S. Jerome and S. Francis,” now in the Palazzo Pensa. In S. Onofrio of Florence is a much lauded and much-debated picture of the “Last Supper” of the Palazzo Vecchio; it is, however, in a very remote and imperfect copy, and not a work of the master. It has been ascribed to Perugino by some connoisseurs, but others to Raphael; it may more probably be by some different pupil of the Umbrian master.

PERUKE, an artificial head of hair, a wig. The word is from Fr. perruque, an adaptation of Ital. parrucca or parrucca. This is usually taken from Ital. pelo, hair; Lat. pilus, Span. peluca, and Sardinian piliaca, lock or tuft of hair, as the view. In the 17th century the English forms which the French word took, such as perruque or perruque, were corrupted into perwuye, and thence into perywug, perwug, and lastly "perwieg," which again was shortened into "wig," the
PERUZZI—PESCADEROS 281

common term for all types of artificial heads of hair. Perugino is sometimes confined to the heavy full-bottomed wigs worn from the reign of Charles II. to the introduction of the light, tailed wig of the 18th century.

PERUZZI, BALDASSARE (1481-1530), Italian architect and painter of the Roman school, was born at Ancajano, in the diocese of Volterra, and passed his early life at Siena, where his father resided. While quite young Peruzzi went to Rome, and there studied architecture and painting; in the latter he was at first a follower of Perugino. The choir frescoes in Sant' Onofrio on the Janiculan Hill, usually attributed to Pinturicchio, are by his hand. One of the first works which brought renown to the young architect was the villa on the banks of the Tiber in Rome now known as the Farnesina, originally built for the Sienese Agostino Chigi, a wealthy banker. This villa, like all Peruzzi's works, is remarkable for its graceful design and the delicacy of its detail. It is best known for the frescoes painted there by Raphael and his pupils to illustrate the stories of Psyche and Galatea. One of the loggie has frescoes by Peruzzi's own hand—the story of Medusa. On account of his success Peruzzi was appointed by Leo X. in 1520 architect to St Peter's at a salary of 250 scudi; his design for its completion was not, however, carried out. During the sack of Rome in 1527 Peruzzi barely escaped with his life, on condition of his painting the portrait of Constantin de Bourbon, who had been killed during the siege (see Vasari). From Rome he escaped to Siena, where he was made city architect, and designed fortifications for its defence, a great part of which still exist. Soon afterwards he returned to Rome, where he made designs for a palace for the Orsini family, and built the palaces Massimi and Vidoni, as well as others in the south of Italy. He died in 1536, and was buried by the side of Raphael in the Pantheon. Peruzzi was an eager student of mathematics and was also a fair classical scholar. Like many of the great artists of his time, he was remarkable for the varied extent of his knowledge and skill. A most able architect, a fair painter, and a scientific engineer, he also practised minor arts, such as stucco-work in relief, sgraffito, and the decorative painted arabesques which the influence of Raphael did so much to bring into use. His best existing works in fresco are in the Castel dell'Albero and the church of Fontegiusta in Siena. For Siena Cathedral he also designed a magnificent wooden organ-case, painted and gilt, rich with carved arabesques in friezes and pilasters; he also designed the high altar and the Cappella del Battista.

His chief pupil was the architect Serlio, who, in his work on architecture, gratefully acknowledges the great debt he owed to Peruzzi's instruction. The English National Gallery possesses an interesting drawing by his hand. The subject is the "Adoration of the Magi," and it is one of a group of five, the other four being portraits of Michelangelo, Raphael, and Titian. The Uffizi and the library at Siena contain a number of Peruzzi's designs and drawings, many of which are now of priceless value, as they show ancient buildings which have been destroyed since the 16th century.

PERUGINIUM 1 VENERIS, the Vestig of Venus, a short Latin poem. The author, date, and place of composition are unknown. The poem probably belongs to the 2nd or 3rd century A.D. An article signed L. Raquettaeus in the Classical Review (May 1905) assigns it to Sidonius Apollinaris (5th cent.). It was written professedly in early spring on the eve of a three-nights' festival of Venus (probably April 1-3). It describes in poetical language the annual awakening of the vegetable and animal world through the goddess. It consists of ninety-three verses in trochaic septennarii, and is divided into strophes of unequal length by the refrain:

1 Peruginiurn was the term for a nocturnal festival in honour of some divinity, especially Bona Dea.

281 Edito princeps (1577): modern editions by F. Bicheler (1859), A. Riese, in Anthologia latina (1869), F. Bähr in Unedierten lateinischen Gedichten (1873); S. G. Owen (with Catullus, 1893). There are translations into English verse by Thomas Stanley (1864) and Thomas Parnell, author of The Hornet; on the text see J. W. Mackail in Journal of Philology (1888), vol. xvii.

PESARO (anc. Pisaurnum, q.v.), a city and seaport of the Marches, Italy, the capital of the province of Pesaro and Urbino, situated on the coast of the Adriatic 37 m. N.W. of Ancona by rail, on the right bank of the Foglia, the ancient Pissurus. The ground on which it is built is only from 10 to 40 ft. above the sea, but it is surrounded by hills—on the E. by Monte Ardizio, on the W. by Monte Accio or San Bartolo, which derives one of its names from the tradition that the Roman dramatist L. Attius was born and buried on the spot. Upon this hill was the Villa Imperiale, the foundation stone of which was laid by the emperor Frederick III., built by the Sforza, and decorated with fine stucco ceilings and wall paintings and pavements of majolica plaques. A new palace was begun in 1530 by the Genga for Eleonora Gonzaga, but never finished. The city walls were in 1830 transformed into a public promenade. Besides the ancient cathedral of the Annunciation (restored since 1866) with a 12th-century mosaic pavement, there are a number of smaller churches, several with Gothic portals. One of these, the church of San Francesco, now used as a cathedral, contains the "Coronation of the Virgin" by Giovanni Bellini, the largest and most important of his works outside Venice. The most conspicuous buildings are the prefecture (a palace originally erected in 1455-1465 by the Dalmatian architect Luciano da Laurana for the Sforza, and restored by Francesco Maria della Rovere in the 16th century, the Rossini theatre (opened in 1818), the fortress of Rocca Costanza (built by Costanzo Sforza in 1474, Laurana being the architect), and the large lunatic asylum. The composer Gioacchino Rossini, who was a native of Pesaro, left all his fortune to found a musical lyceum in the city, and his statue by Moretelli (1864) stands near the railway station. The Olivieri library (established by the antiquary of that name, author of Marmora piazenium, &c.) contains about 14,000 volumes, MSS. of Tasso, &c., inscriptions and various antiquities, and a very fine collection of majolica (one of the best in Italy) from the old Urbino and other manufactories. The Museo Mosca, left by its owner to the town, contains important collections of faience, furniture, &c. Among the industries of Pesaro are the growing, spinning and weaving of silk, tanning, ironfounding, and the manufacture of glass and pottery. It is also the centre of a rich agricultural district. The harbour is of no great importance, but there is a small export trade in wine, olives, silk and glass. Pop. (1901), 14,708 (town); 24,832 (commune).

The town, by Vitiges the Goth, was the town was restored and strengthened by Belisarius, and afterwards along with Ancona, Fano, Senigallia, and Rimini formed the Pentapoli Marittima. In the course of the 13th century Pasaro was sometimes under the government of the popes, sometimes under that of the emperors; but the Malatesta family, which first took root in the city about 1285, gradually became the real masters of the place. In 1445 they sold their rights to Francesco Sforza; and in 1512, through the influence of Julius II., the Sforza were supplantcd by his nephew Francesco Maria, duke of Urbino. Leo X. took the city away from Francesco and gave it to Lorenzo de' Medici; but on Lorenzo's death Francesco was restored and Pesaro became the ordinary residence of the dukes of Urbino till the death of Francesco Maria II. in 1631, when it reverted to the States of the Church. It has formed part of the present kingdom of Italy since 1866. Terenzo Mamiani della Rovere, poet and statesman, was born at Pesaro in 1800.

PESCADEROS (i.e. fishers,) a group of islands (called by the Japanese 魚口 to or 魚口市) lying 30 m. west of Formosa, from which they are separated by the Pescadores Channel, about the tropic of Cancer. The islands number 48 (21 inhabited), have a coast-line of 98-67 miles, a total area of 85-59 sq. m., and a population of about 53,000, principally Chinese. Flat and with unproductive soil, they are swept during one
half of the year by violent N.E. winds, and also lie full in the path of the numerous typhoons that rush up the Strait of Formosa. Meteorological observations taken by the Japanese during a period of three years show that the annual average number of stormy days is 237. The anchorage is at Mako (Makū or Makun) on the principal island of Penghu. The chief industry is fishing (whence the old Spanish name which has come into general use) and dried fish are exported.

PESCARA, FERNANDO FRANCESCO DAVALOS, MARQUIS OF (1489-1525), Italian condottiere, was born at Naples, his family being of Spanish origin. Rodrigo (Ruy) Lopez Davalos, his great-grandfather, a noble of Toledo, who had taken an active part in the civil wars of Castile in the reign of John II. (1497-1454), had been driven into exile, and died at Valencia. Fadiso (Ignatius), his son, entered the service of the Viscount of Arezzo, and in 1499 followed his master to Italy, and there, making an advantageous marriage with a lady of the family of Aquino, was created marquis of Pescara. His son Alphonso, who succeeded him in the marquisate, married a lady of the Sicilian branch of the Spanish family of Cardona, and when he was treacherously killed, during a French invasion of Naples, his only son Fernando, or Ferrante, was a child in arms. At the age of six the boy was betrothed to Vittoria Colonna (q.v.), daughter of the general Fabrizio Colonna, and the marriage was celebrated in 1509. His position as a noble of the Aragonese party in Naples made it incumbent on him to support Ferdinand the Catholic in his Italian wars. This town overruns the site of the ancient Aternun, the terminus of the Via Claudia Valeria, and up to 1867 a fortress of some importance. The railway from Sulmona follows the Pescara valley and joins the coast line to Brindisi at Pescara. In this valley, 22 m. from the sea, was the site of the ancient Interpromium, a town belonging probably to the Paelegni, and not far off is the very fine Cistercian abbey church of S. Clemente di Casauria, founded by the emperor Louis II. in 871. The present building belongs to the 12th century. The sculptures of the portals, the pulpit, the Paschal candelabrum, &c., and the bronze doors of this period are important. The chronicle of the abbey, of the end of the 11th century, is in the Bibliothèque nationale at Paris.

See V. Bindi, Monumenti degli Abissi (Naples, 1889), pp. 405 sqq.; P. L. Calore in Archivio storico dell'arte (Rome, 1891), iv. 9 sqq.

PESCHIERA SUL GARDA, a fortress of Venetia, Italy, in the province of Verona, on an island in the Mincio at its outlet from the lake of Garda, 77 m. by rail E. of Milan. It was one of the famous fortresses of the Quadrilateral, the chief bulwark of the Austrian rule in Italy until 1866 (Manua, Legnano and Verona being the other three) and has played a prominent part in all the campaigns conducted in north Italy, especially during the Napoleonic wars. It was taken by the Piedmontese and the Austrians, after a gallant defence by General Rath lasting six weeks, on the 30th of May 1848, and since that date has been in Italian hands.

PESCI, a town of Tuscany, Italy, in the province of Lucca, from which it is 15 m. E.N.E. by rail, 203 ft. above sea-level. Pop. (1901), 12,400 (town); 18,000 (commune). The cathedral, restored in 1903, contains the fine chapel of the Turini family, built for Baldassare Turini (d. 1540) by Giuliano di Baccio of Florence, with his tomb by Raffaello da Montelupo. The town also has some buildings by Lazzaro Buggiano, the papal and adoptive son of Brunelleschi. It has silk and paper manufactories.

PESETA, a silver coin and unit of value, the Spanish equivalent of the French, Belgian and Swiss franc, the Italian lira and the Greek drachma in the Latin monetary union. The peso (Lat. pensum, weight), of which pezeta is a diminutive, was a Spanish coin of gold, peso de oro, or silver, peso de plata, once current in Spain and her colonies, and now the name of a silver coin of many South American states. The peso is also the name of the Mexican dollar.

PESHAWAR, a city of British India, the capital of the North-West Frontier Province, giving its name to a district. The city is situated near the left bank of the river Bara, 11 m. from Jamrud at the entrance of the Khyber Pass, the railway station being 1588 m. north-west of Calcutta; pop. (1901), 95,147. Two miles west of the native city are the cantonments, forming the principal military station of the North-West Frontier Province. Peshawar lies within a horseshoe ring of hills on the edge of the mountain barrier which separates India from Afghanistan, and through it have passed nearly all the invaders from the north. The native quarter is a huddle of flat-roofed houses within mud walls, crowded along narrow, crooked alleys; there is but one fairly wide street of shops. Here for many centuries the Povindkas, or Afghan travelling merchants, have brought their caravans from Kabul, Bokhara and Samarkand every autumn. They
PESHIN—PESSIMISM

Pessimism (from Lat. pessimus, worst), a word of modern coinage,\(^1\) denoting an attitude of hopelessness towards life, a vague general opinion that pain and evil predominate in human affairs. It is the antithesis of “optimism,” which denotes the view that on the whole there is a balance of good and pleasure, or at least that in the long run good will triumph. Between optimism and pessimism is the theory of “melliorism,” according to which the world on the whole makes progress in goodness. The average man is pessimist or optimist not on theoretical grounds, but owing to the circumstances of his life, his material position, the influence of his body health, his general temperament. Perhaps the most characteristic example of unsystematic pessimism is the language of Ecclesiastes, who concludes that “all is vanity.”

Pessimism and optimism have, however, been expressed in systematic philosophical forms, a brief summary only of which need here be given. Such systems have been elaborated chiefly by modern thinkers, but the germs of the ideas are found widely spread in the older Oriental philosophies and in pre-Christian European thought. Generally speaking, pessimism may be found in all pantheistic and materialistic systems. It is important, however, to point out an essential distinction. The thinker who sees man confronted by the infinite non-moral forces presumed by natural pantheism inevitably predominating over the finite powers of men may appear to the modern Christian theologian or to the evolutionist as a hopeless pessimist, and yet may himself have concluded that, though the future holds out no prospect save that of annihilation, man may yet by prudence and care enjoy a considerable measure of happiness. Pessimism, therefore, depends upon the individual point of view, and the term is frequently used merely in a condemnatory sense by hostile critics. The attitude of a man who denies the doctrine of immortality and rejoices in the denial is not strictly pessimistic. A Christian again may be pessimistic about the present; he may logically be optimistic about the future—a teleological view of the universe implies optimism on the whole; the agnostic may be indifferent to, or pessimistic, regarding the future, while exceedingly satisfied with life as he finds it.

This complex view of life is exemplified by Plato, whose general theory of idealism is entirely optimistic. In analysing the world of phenomena he necessarily takes a pessimistic view because phenomena are merely imitations more or less removed from reality, i.e. from the good. Yet the idealistic postulate of a summa bonum is in result optimistic, and this view predominated among the Stoics and the Neoplatonists. The Epicureans, on the other hand, were empirical pessimists. Man is able to derive a measure of enjoyment from life in spite of the non-existence of the orthodox gods; yet this enjoyment is on the whole negative, the avoidance of pain. A similar view is that of the ancient sceptics.

Oriental pessimism, at least as understood by Europeans, is best exemplified in Buddhism, which finds in human life sorrow and pain. But all pain and sorrow are incidental to the human being in his individual capacity. He who will cast aside the “Bonds,” the “Intoxications,” the “Hindrances,” and tread the Noble Eightfold Path (see BuDivavamsa) which leads to Nirvana, will attain the ideal, the “Fruit of Arahatship,” which is described in terms of glowing praise in the Pali hymns. This, the original doctrine of the Buddha, though not adopted in the full sense by all his followers, is in fact at least as optimistic as any optimism of the West. To call it “pessimism” is merely to apply it to a characteristically Western principle according to which happiness is impossible without personality. The true Buddhist on the contrary looks forward with enthusiasm to this absorption into eternal bliss.

In Europe on the whole the so-called pessimistic attitude was commoner in the Teutonic north than in the Mediterranean basin. But even here the hopefulness as regards a future life, in which the inequalities of the present would be rectified, compensated for the gloomy fatalism with which the present was

1 The earliest example given in the New English Dictionary is in S. T. Coleridge’s Letters (1794).
PESSINUS—PESTALOZZI

regarded. The advent of Christianity, with its categorical assertion of future happiness for the good, to a large extent did away with pessimism in the true sense. In Leibnitz we find a philosophic or religious optimism, which saw in the universe the perfect work of a God who from all possibilities selected the best. Kant, though pessimistic as regards the actual man, is optimistic regarding his moral capacity. To Hegel similarly the world, though evil at any moment, progresses by conflict and suffering towards the good.

Passing over the Italian Leopardi we may notice two leading modern pessimists, Schopenhauer and von Hartmann. Schopenhauer emphasizes the pessimistic side of Hegel's thought. The universe is merely blind Will, not thought; this Will is irrational, purposeless and therefore unhappy. The world being a picture of the Will is therefore similarly unhappy. The state of unhappiness, and the satisfaction of desire is therefore merely the removal of pain. Von Hartmann's doctrine of the Unconscious is in many respects similar to Schopenhauer's doctrine of the Will. The Unconscious which combines Will and Reason is, however, primarily Will. The workings of this Will are irrational primarily, but, as in its evolution it becomes more rationalized and understands the whole meaning of the Weltanschauung, it ultimately reaches the point at which the desire for existence is gone. This choice of final nothingness differs from that of Schopenhauer in being collective and not individual. The pessimism of Schopenhauer and Hartmann does not, however, exclude a certain ultimate mysticism, which bears some analogy to that of Buddhism.

Pessimism is naturally connected with materialist, optimism with idealist, views of life. The theories of the modern evolutionist school, however, have introduced into materialistic theory a new optimistic note in doctrines such as that of the survival of the fittest. Such doctrines regard the progress of humanity as on the whole tending to the greater perfection, and are marked by optimism in contrast with earlier theories that progressive difference bears on the whole but to the decay of the human species. Similarly the cynical contempt which Nietzsche shows for morality and the conventional virtues is counterbalanced by the theory of the Übermensch, the highest type of manhood which by struggle has escaped from the ordinary standards of normal humanity.

PESSINUS (Πεσίνος, Πεσίνος), an ancient city of Galatia in Asia Minor, situated on the lowest southern slope of Mt. Dindymus, on the left bank of the river Sangarius, not far from its source. The ruins, discovered by Texier, lie round the village of Bala-Hissar, 8 or 9 m. S.E. of Sivri-Hissar. They include a theatre in partial preservation, but they have been mostly covered under the sand, which is largely built out of them. Originally a Phrygian city, probably founded at the Persic Royal Road, it became the capital of the Gallic tribe Tolistobogii and the chief commercial city of the district. It contained the most famous sanctuary of the mother of the gods (Cybele), who here went by the name of Agdistis, and was associated with the god Attis, as elsewhere with Sabazius, &c. Her priests were also princes, who bore rule not only in the city (the coinage of which, beginning about 100 B.C., was for long issued by them) but also in the country round, deriving a large revenue from the temple estates; but in the time of Strabo (A.D. 19-20) their privileges were much diminished. The high-priest always bore the title of the Phrygian king, but in the 2nd century B.C. the second king of the empire was at Rome, and the emperors divided between the Gauls and the old priestly families. Like Anycya and Tavium, Pessinus was Romanized first and Hellenized afterwards. Only about A.D. 165 did Hellenic ways and modes of thought begin to be assumed; before that we find a deep substratum of Celtic feeling and ways, on which Roman elements had been superimposed without filtering through a Hellenic medium. Christianity was introduced late; it cannot be traced before the 4th century.

When Galatia was divided into two provinces (A.D. 386-395) Pessinus was made the capital of Galatia Secunda or Salutaris, and it became a metropolitan bishopric. After the 16th century it disappears from history, being supplanted, from the beginning of the period of Saracen invasion, by the impregnable fortress Justinianopolis (Sivri-Hissar), which became the capital and the residence of the bishop, thenceforward called "archbishop of Pessinus or of Justinianopolis." (J. C. A.)

PESTALOZZI, JOHANN HEINRICH (1746-1827), Swiss educational reformer, was born at Zürich on the 12th of January 1746. His father died when he was young, and he was brought up by his mother. At the university of Zürich he was associated with Lavater and the party of reform. His earliest years were spent in schemes for improving the condition of the people. The death of his friend Bluntschli turned him however from politics, and induced him to devote himself to education. He married at twenty-three and bought a property on the land at Neuhof in Aargau, where he attempted the cultivation of rye. Pestalozzi knew nothing of business, and the plan failed. Before this he had opened his farm-house as a school; but in 1780 he had to give this up also. His first book published at this time was The Evening Hours of a Hermite (1780), a series of aphorisms and reflections. This was followed by his masterpiece, Leonard and Gertrude (1781), an account of the gradual reformation, first of a household, and then of a whole village, by the efforts of a good and devoted woman. It was read with avidity in Germany, and the name of Pestalozzi was rescued from obscurity. The French invasion of Switzerland in 1798 brought into prominence his truly heroic character. A number of children were left in Canton Unterwalden on the shores of the lake of Lucerne, without parents, home, food or shelter. Pestalozzi collected a number of them into a deserted convent, and spent his energies in reclaiming them. During the winter he personally tended them with the utmost devotion, but in June 1799 the building was required by the French for a hospital, and his charges were dispersed. In 1801 Pestalozzi gave an exposition of his ideas on education in the book How Gertrude teaches her Children. His method is to proceed from the easier to the more difficult.

To begin with observation, to pass from observation to consciousness from consciousness to speech. Then come measuring, drawing, writing, numbers, and so reckoning. In 1799 he had been enabled to establish a school at Burgdorf, where he remained till 1804. In 1802, he went as deputy to Paris, and did his best to interest Napoleon in a scheme of national education; but the great conqueror said that he could not trouble himself about the alphabet. In 1805 he removed to Yverdon on the Lake of Neuchâtel, and for twenty years worked steadily at his task. He was visited by all who took interest in education—Talleyrand, Cap d'Istria, and Mme de Staël. He was praised by Wilhelm von Humboldt and by Fichte. His pupils included Ramsauer, Delbrück, Blochmann, Carl Ritter, Fröbel and Zeller. About 1815 dissensions broke out among the teachers of the school, and Pestalozzi's last ten years were...
chequered by weariness and sorrow. In 1825 he retired to Neuboh, the home of his youth; and after writing the adventures of his life, and his last work, the Swau's Song, he died at Brugg on the 17th of February 1827. As he said himself, the real work of his life did not lie in Burgdorf or in Yverdon. It lay in the principles of education which he practised, the development of his observation, the training of the whole man, the sympathetic application of the teacher to the taught, of which he left an example in his six months' labours at Stanz. He had the deepest effect on all branches of education, and his influence is far from being exhausted.

Petraliuzzi's complete works were published at Stuttgart in 1819-1826, and an edition by Seyffarth appeared at Berlin in 1851. Volumes on his life and teaching have been written by De Guîmps (1889), Barnard (1862), Krüsi (1875) and Pinloche (1901).

PETALITE, a mineral species consisting of lithium aluminium silicate, LiAl(SiO₃)₂. The monoclinic crystals approach spodumene (q.v.) in form, which is also a lithium aluminium silicate with the formula LiAl(SiO₃)₂. There is a perfect cleavage parallel to the basal plane, and the mineral usually occurs in platy cleavage masses; on this account it was named, from Gr. πέτρια (a leaf). The hardness is 6½ and the specific gravity 2·4 (that of spodumene being 3·10). The mineral is colourless or occasionally reddish, varies from transparent to translucent, and has a vitreous lustre. It was discovered in 1800 as cleavage masses in an iron mine on the island of Utö in the Stockholm archipelago, where it is associated with lepidolite, tourmaline (rubellite and indicolite) and spodumene. A variety known as "castor" is found as transparent glassy crystals associated with pollex (q.v.) in cavities in the granite of Elba. (L. J. S.)

PETARD (Fr. pétard, pêter, to make a slight explosion), a device formerly used by military engineers for blowing in a gate or other barrier. It consisted of a small metal or wooden case, usually of sugar-loaf shape, containing a charge of powder and fired by a fuse.

PETAU, DENYS (1583-1652), Jesuit scholar, better known as DIONYSIUS PETAVIUS, was born at Orleans on the 21st of August 1583. Educated at Paris University, he came under the influence of Isaac Scaliger, who directed his attention towards the obscurer fathers of the Church. In 1603 he was appointed to a lectureship at the university of Bourges, but resigned his place two years later, in order to enter the Society of Jesus. For many years he was professor of divinity at the Collège de Clermont, the chief Jesuit establishment in Paris; there he died on the 28th of December 1652. He was one of the most brilliant scholars in a learned age. Carrying on and improving the chronological labours of Scaliger, he published in 1627 an Opus de doctrina temporum, which has been often reprinted. An abridgment of this work, Rationalium temporum, was translated into French and English, and has been brought down in a modern reprint to the year 1849. But Petavius's eminence chiefly rests on his vast, but unfinished, De theologis dogmaticis, the first systematic attempt ever made to treat the development of Christian doctrine from the historical point of view.

PETCHENEGS, or PATZINAKS, a barbarous people, probably of Turkish race, who at the end of the 9th century were driven into Europe from the lower Ural, and for about 500 years wandered through the northern frontier of the East Roman Empire. (See Turks.)

PETER, the chief of the Twelve Apostles. He is known also by other names: (a) "Simon" (Σίμων) in Mark four times and Luke seven times. This use is only found in narrative before the story of the mission of the apostles: it is also found in speeches; Matthew once, Mark once and Luke twice. (b) "Simon who is called Peter" is found in Matthew twice and Acts four times. (c) "Simon Peter" is found in Matthew once, Luke once, John seventeen times (and perhaps also in 2 Peter i. 1, where the text varies between Simon and Symeon). (d) "Peter" is found in Matthew nineteen times, Mark eighteen times, Luke sixteen times, Acts fifty-one times, John fifteen times, Galatians twice, 1 Peter once. (e) "Cephas" is found in John once, Galatians four times, 1 Corinthians four times. (f) Symeon (Σιμών) is found in Acts once. It appears that the apostle had two names, each existing in a double form—Greek and Hebrew, Symeon (Σιμών) which was Graecized according to the sound into Simon, and Cephas (Κέφας) which was Graecized according to the meaning into Peter (Πέτρος). Symeon and Peter are both well-known names in Aramaic and Greek respectively, but Cephas and Peter are previously unknown. Symeon was no doubt his original Aramaic name, and the earliest gospel, Mark, which has some claim specially to reproduce Petrine tradition, is careful to employ Simon until after the name Peter had been given, and not then to use it again. The Gospels agree in regarding Cephas or Peter as an alternative name, which is given by Christ. But they differ as to the occasion. According to Mark iii. 13 sqq. it was given on the occasion of the mission of the Twelve. According to John i. 42 it was given at his first call. According to Matt. xvi. 13 sqq. it was given after the recognition of Jesus as Messiah at Caesarea Philippi. This last account is the only one which describes any circumstances (for a further discussion see § 3 (c) below).

According to the Gospels Peter was the son of John (Ἰωάννης, John i. 42, xxi. 15 seq.) or Jonas (Ἰωάννης, Matt. xxvii. 17). According to Mark i. 29 he was a fisherman of Capernaum, but John i. 44 describes him and his brother Andrew as of Bethesda. From Mark i. 30 he is seen to have been married, and 1 Cor. ix. 5 suggests (but another interpretation is possible) that his wife went with him on his missionary journeys. In 1 Pet. v. 13 Mark is referred to as his son, but this is usually interpreted of spiritual kinship. According to legend (Acta Neret et Achillei, and Acta Philippi) he had a daughter Petronilla, but there is no reason for thinking that this is historical.

The Gospel narratives are unanimous in describing Peter as one of the first disciples of Christ, and from the time of his call he seems to have been present at most of the chief incidents in the narrative. He formed together with the sons of Zebedee to some extent an inner circle within the Twelve, and this favoured group is specially mentioned as present on three occasions—the raising of the daughter of Jairus (Mark v. 22-43; Matt. ix. 18-36; Luke viii. 41-50), the transfiguration (Mark i. 2 sqq.; Matt. xvii. 1 sqq.; Luke ix. 28 sqq.) and the scene in the Garden at Gethsemane (Mark xiv. 32 sqq.; Matt. xxvi. 36 sqq.). He is also specially mentioned in connexion with his call (Mark i. 16-20; Matt. iv. 18 sqq.; Mark vi. 17 sqq.; John i. 40-51), and the eschatological discourse of his master's betrayal (Mark i. 21 sqq.; Matt. xxvii. 14 sqq.; Luke iv. 38 sqq.); the mission of the Twelve Apostles (Mark ii. 13 sqq.; Matt. x. 1 sqq.; Luke xi. 12 sqq.); the storm on the Lake of Galilee (Mark vi. 45 sqq.; Matt. xiv. 22 sqq.; John vi. 16 sqq.); the Messianic recognition at Caesarea Philippi (Mark vii. 27 sqq.; Matt. xvi. 16 sqq.; Luke ix. 18 sqq.); the incident of the payment of tribute by the coin found in the fish caught by Peter (Matt. xvii. 25 sqq.) and with various questions leading to parables or their explanations (Mark xii. 27 sqq.; Luke ii. 41; Matt. xviii. 21 sqq.; Mark x. 28; Matt. xix. 27; Luke xvii. 28). In the week of the Passion he appears in connexion with the incident of the withered fig-tree (Mark xi. 21; Matt. xxvii. 28), introducing the eschatological discourse (Mark xxi. 3 sqq.) and as prominent during the Last Supper (Luke xxii. 3 sqq.; John xiii. 4 sqq.; Mark xiv. 27 sqq.; Matt. xxvi. 31 sqq.).
was present in Gethsemane, and tried to offer some resistance to the arrest of Jesus (Mark xiv. 47; Matt. xxvi. 51; Luke xxii. 50; John xviii. 10). After the arrest he followed the Lord to the scene of the trial, but denied him and fled. The message of the young man at the tomb (Mark xvi. 4) was especially addressed to Peter and it is clear that the genuine conclusion of Mark must have contained an account of an appearance of the risen Lord to him.

Out of this mass of incidents the following are central and call for closer critical consideration.

1. The Call of St. Peter.—(Mark i. 16–20; Matt. iv. 18–22; Luke v. 1–11; John i. 40–42). The account in Matthew is practically identical with that in Mark and is no doubt taken from the Marcan source, but Luke and John have different traditions. The main points are as follows: according to Mark, at the beginning of the Galilean ministry Jesus saw Peter and Andrew fishing. He called them, and they joined him. After this he went with them to Capernaum, preached in the synagogue, and healed Peter’s wife’s mother. Luke, who certainly used Mark, has partly rearranged this narrative and partly rejected it in favour of a different version. According to him the visit to Capernaum and the healing of the wife’s mother preceded the call of Peter, and this was associated with a tradition of a miraculous draught of fishes. The advantage of the Lucan reconstruction, so far as the first part is concerned, is that it supplies a reason for Peter’s ready obedience, which is somewhat difficult to understand if he had never seen Jesus before. But it seems probable that this is the motive which led to the redactional change in Luke, and that the Marcan account, which is traditionally connected with Peter, ought to be followed. With regard to the narrative of the miraculous draught of fishes, the matter is more complicated. Luke obviously preferred this narrative to the Marcan account, but the fact that the same story comes in John xxi. suggests that there was an early tradition of some such incident of which the actual occasion and circumstances were undetermined. Luke’s purpose in connect with it the call of Peter, the writer of John xxi. with his resurrection: probably both are of the nature of redactional guesses, and the Marcan account must be regarded as preferable to either. The Johannine account of the call of Peter is quite different. According to this it took place immediately after the baptism of Jesus, in Judaea not in Galilee. It is connected with the giving of the name Peter, which in Mark was not given until much later.

2. The Confession of Peter at Caesarea Philippi.—(Mark viii. 27–33; Matt. xvi. 13–23; Luke ix. 18–22). According to Mark, Peter, in answer to the question of Jesus, recognized that He was the Messiah but protested against the prophet’s exaltation of the Son of Man. According to the Markan narrative, Peter’s answer supplies a reason for his suffering which Jesus then added. This narrative is followed, with the exception of the last part, by Luke, who as usual is inclined to omit anything which could be regarded as derogatory to the Apostles. Matthew also uses the Marcan narrative, but adds to it a new section from some other source which suggests that the name of Peter was conferred on this occasion—not, as Mark says, at the first mission of the Twelve—and confers on him the keys of the kingdom of heaven and the right of binding and loosing. This must be probably interpreted as a reference to the prophecy concerning Elíasam in Isa. xxii. 22, and to technical use of the words “binding” and “loosing” by the scribes in authoritative decisions as to the obligations of the law. It thus confers on Peter a position of quite unique authority. It must, however, be noted that the power of binding and loosing is given in Matt. xviii. 18 to the whole body of disciples. This seems to be an alternative version, also found only in Matthew. The question of the historical character of the Mattaean addition to the Marcan narrative is exceedingly difficult; but it is hard to think that if it were really authentic it would have been omitted from all the other gospels, and it perhaps belongs to the little group of passages in Matthew which seem to represent early efforts towards church legislation, rather than a strictly historical narrative. Besides it is noticeable that in one other point Matthew has slightly remodelled the Marcan narrative. According to the latter Jesus asked, “Whom say men that I am?” and Peter replied “the Messiah,” without qualification. But in Matthew the question is changed into “Whom say men that the Son of Man is?” and, whatever may be the original meaning of the phrase, “the son of man,” it cannot be doubted that the gospels it means Messiah. Thus the simple answer of Peter in Mark would be meaningless, and it is replaced by “The Messiah, the son of the living God,” which is no longer a recognition of the Messiahship of Jesus (this is treated in Matthew as an already recognized fact, cf. x. 23, xii. 40, &c.), but is a definition and an exaltation of the nature of the Messiah.

3. The Conduct of Peter after the Betrayal.—The consideration of this point brings one into touch with the two rival traditions as to the conduct of the disciples after the betrayal and crucifixion of the Lord—the Galilean and the Jerusalem narratives. There is one incident which must in any case be accepted as it is found in both narratives. This is the denial of Peter. It appears that Peter did not stay with the disciples and neither returned home immediately to Galilee (according to the Galilean tradition) nor sought hiding in Jerusalem (according to the Jerusalem tradition), but followed the Lord at a distance and was a witness of at least part of the trial before the Sanhedrim. He was detected and accused of being a disciple, which he denied, and so fulfilled the prophecy of Jesus that he would deny Him before the cock crowed.

But putting this incident aside, the Galilean and Jerusalem traditions do not admit of reconciliation with one another. The former is represented by Mark. According to it the disciples all fled after the betrayal (though Peter waited until after the denial), and afterwards saw the risen Lord in Galilee. The details of this narrative are unfortunately lost, as the genuine conclusion of Mark is not extant. But Mark xiv. 28 and xvi. 7 clearly imply a narrative which described how the disciples returned to Galilee, there saw the risen Lord, and perhaps even how they then returned to Jerusalem in the strength of their newly recovered faith, and so brought into existence the church of Jerusalem as we find it in the Acts. It is also clear from Mark xvi. 7 that Peter was in some special way connected with this appearance of the risen Lord, and this tradition is confirmed by 1 Cor. xv. 5, and perhaps by Luke xxiv. 34.

The Jerusalem narrative is represented especially by Luke and John (excluding John xxi. as an appendix). According to this the disciples, though they fled at the betrayal, did not return to their homes, but remained in Jerusalem, saw the risen Lord in that city, and stayed there until after the day of Pentecost. Attempts to reconcile these two narratives seem to be found in Matthew and in John xxi.

Obviously the choice which has to be made between these traditions cannot be adequately discussed here: it must suffice to say that intrinsic and traditional probability seem to favour the Galilean narrative. If so, one must say that after the denial Peter returned to Galilee—probably to resume his trade of fishing—and he there saw the risen Lord. This appearance is referred to in 1 Cor. xv. 5, and was certainly described in the lost conclusion of Mark. An account of it is preserved in John xxi., but it is here connected—probably wrongly—with a miraculous draught of fishes, just as the account of his call is in Luke.

Immediately after the resurrection there is a missing link in the history of Peter. We know that he saw the risen Lord, and, according to the most probable view, that this was in Galilee; but the circumstances are unknown, and we have no account of his return to Jerusalem, as at the beginning of the Acts the disciples are all in Jerusalem, and the writer, in contradiction to the Marcan or Galilean narrative, assures that they had never left it. The first part of the Acts is largely concerned with
the work of Peter. He appears as the recognized leader of the Apostles in their choice of a new member of the Twelve to take the place of Judas Iscariot (Acts i. 15 sqq.); on the day of Pentecost he seems to have played a prominent part in explaining the meaning of the scene to the people (Acts ii. 14 sqq.); and soon afterwards was arrested by the Jews on the charge of being a ring-leader in the disorders caused by the healing of the lame man at the "Beautiful" gate of the temple, but was released. After this he appears as the leader of the apostles in the story of Ananias and Sapphira, who perished at his rebuke for their duplicity (Acts v. 1–11). The last episode of this period is another arrest by the priests, which ended in his being scourged and released (Acts v. 17 sqq.).

After Peter's attention was directed to the growth of Christianity in Samaria, and he and John made a journey of inspection through that district, laying hands on those who had been baptized in order that they might receive the Holy Spirit. Here Simon Magus (q.v.) was encountered. He was a magician who had been converted by Philip and baptized; he desired to obtain the power of conferring the Spirit, and offered Peter money for this purpose, but was indignantly repulsed. After this Peter and John returned to Jerusalem.

During the following stay in Jerusalem, the duration of which is not defined, Peter was visited by Paul (Acts ix. 26–29; Gal. i. 18), and a comparison of the chronological data afforded by Gal. i. and ii. points to a year not earlier than 33 (Harnack) or later than 38 (C. H. Turner) for this meeting. According to Galatians, Paul saw none of the apostles on this occasion except Peter and James; it is therefore probable that none of the others were then in Jerusalem.

After this Peter made another journey, visiting especially Lydda, Joppa and Caesarea. His stay at Lydda was marked by the healing of Aeneas (Acts iv. 32–4) and at Joppa by the resurrection of Tabitha or Dorcas. While at Joppa he stayed with Simon the tanner, and thence was summoned to Caesarea to Cornelius the centurion. He hesitated whether to go, but was persuaded by a vision and the injunction to call nothing unclean which God had cleansed. Cornelius was accordingly baptized. This is an important incident, as being the first admission of a Gentile into the church: but he was already "God-fearing," φοβούμενος τοῦ θεοῦ (Acts x. 1), which probably denotes some sort of connexion with the Jewish synagogue, though it is difficult to say exactly what it was. After this incident Peter returned to Jerusalem. The members of the Church were somewhat shocked at the reception of Gentiles; their activities apparently was that the only road to Christianity was through Judaism. They were, however, persuaded by Peter's speech (Acts xi. 1–18); but it is uncertain how far their concession went, and in the light of subsequent events it is probable that they still regarded circumcision as a necessary rite for all Christians.

After the return of Peter to Jerusalem the most important events were the famine at Jerusalem, and the persecution of the Church by Herod. During the latter Peter was put in prison (Acts xii. 3 sqq.), but was released by an angel; he first went to the house of Mary, the mother of John Mark, and afterwards went to "another place." This expression has been interpreted to mean another town, and seems to refer to Joppa, which is relatively near Rome. This last supposition, improbable though it be, is historically important. The persecution of Herod seems to have been in his last year, which was probably A.D. 44–44. There was a marked tendency to make the duration of Peter's episcopate at Rome twenty-five years: and a combination of this tendency with the explanation that the ἐρεσις τῶν is Rome probably is the origin of the traditional dating of the martyrdom of Peter in A.D. 67–68. There is, however, no justification for this view, and ἐρεσις τῶν need not mean more than another house in Jerusalem.

The famine referred to in Acts xi. 27 sqq. probably began before the death of Herod, but it continued after his death, and the relief sent by the church at Antioch to Jerusalem through Paul and Barnabas probably arrived about the year 45. It is not stated in the Acts that Peter was present, and it is therefore usually assumed that he was absent, but Sir W. M. Ramsay has argued in his St Paul the Traveller that the visit of Paul to Jerusalem with the famine relief is the meeting between Paul and Peter referred to in Gal. ii. as the occasion of an agreement between them as to the preaching of the gospel to Jews and Gentiles. This view is not generally accepted, but it has the great advantage of avoiding the difficulty that otherwise Paul in Gal. ii. 1 sqq. must describe as his second visit to Jerusalem what was really his third. According to Ramsay, then, Peter was present during the famine, and made a private agreement with Paul that the latter should proceed to the Gentiles, and so far Gentile Christianity was recognized, but the conditions of the intercourse between Gentile and Jewish Christians were not defined, and the question of circumcision was perhaps not finally settled. According to the more popular view the description in Gal. ii. applies to Acts xv. the so-called council of Jerusalem. This council met after the first missionary journey (c. A.D. 49) of Paul to discuss the question of the Gentiles. Peter, who was present, adopted the view that Gentile Christians were free from the obligation of the law, and this view was put into the form of the so-called Apostolic decrees by James (Acts xv. 23 sqq.).

The next information which we have about Peter is given in Gal. ii. 11 sqq. According to this he went to Antioch and at first accepted the Gentile Christians, but afterwards drew back and was rebuked by Paul. On the ordinary interpretation this must have taken place after the council, and it is exceedingly difficult to reconcile it with the attitude of Peter described in Acts xv., so that Mr C. H. Turner thinks that in this respect the account in Gal. ii. is not chronological, and places the visit of Peter to Antioch before the council. If, however, we take the theory of Sir W. M. Ramsay the matter is simpler. We thus get the compact between Paul and Peter during the famine, then a visit of Peter to Antioch, during which Peter first adopted and afterwards drew back from the position which he had agreed to privately.

This vacillation may have then been one of the causes which led up to the council, which may have been held before, not, as is usually thought, after the sending of the Epistle to the Galatians. For this we have no knowledge of details for which the same certainty can be claimed.

There are, however, various traditions of importance.

The following points are noteworthy. 1 Cor. i. 12 suggests the possibility that Peter went to Corinth, as there was a party there which used his name. It is, however, possible that this party had merely adopted the principles which, as they had often told, perhaps falsely, were supported by the old bishop of the Twelve. Dionysius of Corinth (c. 170) states that Peter was in Corinth. This may represent local tradition or may be an inference from 1 Cor. i. 12. 1 Peter suggests a ministry in the provinces of Asia Minor. There is, of course, nothing improbable in this, and even if 1 Peter be not authentic, it is early evidence for such a tradition, but it is also possible that Peter wrote to converts whom he had not personally made. This tradition is found in Origen (Eus. H.E. iii. 1), Epiphanius (Haer. xxvii., vi.), Jerome (De Vir. ill. 1) and other later writers; but it is possible that it is merely an inference from the epistle. 3 John, however, in his command directs Peter's epistles to "those whom he supposed to have been the first bishop." The first writer to mention it is Origen (Hom. vi. in Lucan.), but it is also found in the Clementine Homilies and Recognitions (Hom. 20, 23; Recog. 16, 68) and probably goes back to the lists of bishops which were drawn up in the 2nd century. Other important references to this tradition are found in Eus. H.E. iii. 26, 2; Apost. Const. vii. 46; Jerome, De Vir. ill. 1; Chronicon paschale; and Liber pontificalis. The tradition of work in Antioch may well be historical. Otherwise it is a rather wild elaboration of Gal. ii. 11. The most important and widespread tradition is that Peter came to Rome; and though this tradition has often been bitterly attacked, it seems to be probable that it is at least in outline quite historical. The evidence for it is earlier and better than that for any other tradition, though it is not quite convincing.

The earliest witness to a residence of Peter in Rome is probably
1 Peter, for (see Peter, Epistles of) it is probable that the reference to Babylon ought to be interpreted as meaning Rome. If so, and if the epistle be genuine, this is conclusive evidence that Peter was in Rome. Even if the epistle be not genuine it is evidence of the same tradition. Nor is corroboration lacking: Clement (c. a.d. 97) refers to Peter and Paul as martyrs (1 Clem. 5-6) and says that “To these men... there was gathered a great company of the elect who... became an example to us.” This points in two ways to a martyrdom of Peter in Rome, (1) because Peter and Paul are co-ordinated, and it is generally admitted that the latter suffered in Rome, (2) because they seem to be joined to the great company of martyrs who are suggested as an example to the Church in Rome. Similarly Ignatius (c. a.d. 115) says to the Romans (Rom. iv.), “I do not command you as Peter and Paul.” The suggestion obviously is that the Romans had been instructed by these Apostles. By the end of the 2nd century the tradition is generally known: Irenæus (3, 1, 1), Clement of Alexandria (comment. on 1 Peter), Origen (Hom. vi. in Lucan), Tertullian (Scorpi. 15, and several passages) are explicit on the point, and from this time onwards the tradition is met with everywhere. There is also a tradition, found in Irenæus (3, 7, 7) and in many later writers, and supported by 1 and 2 Clement and Papias (Eus. H. E. 3, 39, 15) that Mark acted as Peter’s assistant in Rome and that his gospel is based on recollections of Peter’s teaching.

This evidence is probably sufficient to establish the fact that Peter, like Paul, had a wide missionary career ending in a violent death at Rome, though the details are not recoverable. The chronological question is more difficult both as regards the beginning and the end of this period of activity.

The Acts, in describing the visits of Peter to Samaria, Joppa, Lydda and Caesarea, justify the view that his missionary activity began quite early. Gal. ii. 11 and 1 Cor. ix. 5 show that Acts minimizes rather than exaggerates this activity; the Antiochian tradition probably represents a period of missionary activity with a centre at Antioch; similarly the tradition of work in Asia is possibly correct as almost certainly is that of the visit to Rome. But we have absolutely no evidence justifying a chronological arrangement of these periods. Even the silence of Paul in the epistles of the captivity proves nothing except that Peter was not then present; the same is true of 2 Tim. even if its authenticity be undoubted.

The evidence as to the date of his death is a little fuller, but not quite satisfactory. The earliest direct witness is Tertullian, who definitely states that Peter suffered under Nero, the date being 64. Origen also relates the latter detail and adds that at his own request Peter was crucified head downwards. Probably John xxi. 18 seq. is a still earlier reference to his crucifixion. Fuller evidence is not found until Eusebius, who dates the arrival of Peter at Rome in 43 and his martyrdom twenty-five years later. But the whole question of the Eusebian chronology is very confused and difficult, and the text of the Chronicon is not certain. The main objection to this date is based partly on general probability, partly on the language of Clement of Rome. It is more probable on general grounds that the martyrdom of Peter took place during the persecution of Christians in 64, and it is urged that Clement’s language refers to an event of this period. It is quite possible that an error of a few years has crept into the Eusebian chronology, which is probably largely based on early episcopal lists, and therefore many scholars are inclined to think that 64 is a more probable date than 67. As a rule the discussion has mainly been between these two dates, but Sir W. M. Ramsay, in his Church in the Roman Empire, has adopted a different line of argument. He thinks that 1 Peter was written c. a.d. 80, but that it may nevertheless be Petrine; therefore he lays stress on the fact that whereas the tradition that Peter was in Rome is early and probably correct, the tradition that he was martyred under Nero is not found until much later. Thus he thinks it possible that Peter survived until c. 80, and was martyred under the Flavian emperors. The weak point of this theory is that Clement and Ignatius bring Peter and Paul together in a way which seems to suggest that they perished, if not together, at least at about the same time. If this view be rejected and it is necessary to fall back on the choice between 64 and 67, the problem is perhaps insoluble, but 64 has somewhat more intrinsic probability, and 67 can be explained as due to an artificial system of chronology which postulated for Peter an episcopate of Rome of twenty-five years—a number which comes so often in the early episcopal lists that it seems to mean little more than “a long time,” just as “forty years” does in the Old Testament. On the whole 64 is the most probable date, but it is very far from certain: the evidence is insufficient to justify any more definite statement.

For further information and discussion see especially Harnack’s Chronologie, and Bishop Chas’s article in Hastings’s Dictionary of the Bible. The latter is in many ways the most complete statement of the facts at present published.

Caius, who lived in the beginning of the 3rd century (see Eus. H. E. 2, 23), stated that the τρόπος (i.e. probably the burial place, not that of execution) of Peter and Paul were on the Vatican. This is also found in the Acta Petri, 84 (in the Lib. Pont., ed. Duchesne, p. 52 seq., 118 sqq.). From this place no reference is made to the relics (whether genuine or not) were moved to the catacombs in a.d. 258 (cf. the Deposita martyrum, and see Lightfoot’s Clement, i. 240), hence arose the tradition of an original burial in the catacombs, found in the Hieronymian Martyrology.

**PETER I.**

Peter I, called “the Great” (1672–1725), emperor of Russia, son of the tsar Alexius Mikhailowich and Natalia Narushkina, was born at Moscow on the 30th of May 1672. His earliest teacher (submitting the legendary Scotchman Menzies) was the dyak, or clerk of the council, Nikita Zotov, subsequently the court fool, who taught his pupil to spell out the liturgical and devotional books on which the children of the tsar were generally brought up. After Zotov’s departure on a diplomatic mission, in 1688, the lad had no regular tutor. From his third to his tenth year Peter shared the miseries and perils of his family. His very election (1683) was the signal for a rebellion. He saw one of his uncles dragged from the palace and butchered by a savage mob. He saw his mother’s beloved mentor, and his own best friend, Aramton Matveyev, torn, bruised and bleeding, from his retainer’s grasp and hacked to pieces. The haunting memory of these horrors played havoc with the nerves of a supersensitive child. The convulsions from which he suffered so much in later years must be partly attributed to this original shock. During the regency of his half-sister Sophia (1682–1689) he occupied the subordinate position of junior tsar, and after the revolution of 1689 Peter was still left pretty much to himself. So long as he could indulge freely in his favourite pastimes—ship-building, ship-sailing, drilling and sham fights—he was quite content that others should rule in his name. He now found a new friend in the Swiss adventurer, Francois Lefort, a shrewd and jovial rascal, who not only initiated him into all the mysteries of prodigality (at the large house built at Peter’s expense the German settlement) but taught him his true business as a ruler. His mother’s attempt to wean her prodigal son from his dangerous and mostly disreputable pastimes, by forcing him to marry the beautiful but stupid Eudoxia Lopukhina (Jan. 27, 1688), was a disastrous failure. The young couple were totally unsuited to each other. Peter practically deserted his unfortunate consort a little more than a year after their union.

The death of his mother (Jan. 25, 1694) left the young tsar absolutely free to follow his natural inclinations. Tiring of the great lake at Pereyaslav, he had already seen the sea for the first time at Archangel in July 1683, and on the 1st of May 1694 returned thither to launch a ship built by himself the year before. Shortly afterwards he nearly perished during a storm on an adventurous voyage to the Solovetsky Islands in
the White Sea. His natural bent was now patent. From the first the lad had taken an extraordinary interest in the technical and mechanical arts, and their application to military and naval science. He was taught the use of the astrolobe (which Prince Yakov Dolgoruky, with intent to please, had brought him from Paris) by a Dutchman, Franz Timmerman, who also instructed him in the rudiments of geometry and fortifications. He had begun to build his own boats at a very early age, and the ultimate result of these pastimes was the creation of the Russian navy. He had already surrounded himself with that characteristically Petrine institution "the jolly company," or "the company," as it was generally called, consisting of all his numerous personal friends and casual acquaintances. "The company was great but it was not dangerous; there was no knockabout, no extrava
tastical, and shared not only the orgies but also the labours of the tsar. Merit was the sole qualification for promotion, and Peter himself set the example to the other learners by gradually rising from the ranks. In 1695 he had only advanced to the post of "skipper" in his own navy and of "bombardier" in his own army. It was, however, the disreputable Lefort who, for the sake of his own interests, diverted the young tsar from mere pleasure to serious enterprises, by persuading him first to undertake the Azov expedition, and then to go abroad to complete his education.

By this time the White Sea had become too narrow for Peter, and he was looking about him for more hospitable waters. The Baltic was a closed door to Muscovy, and the key to it was held by Sweden. The Caspian remained; and it had for long been a common saying with foreign merchants that the best way of tapping the riches of the Orient was to secure possession of this vast inland lake. But so long as the Turks and Tatars made the surrounding steppes uninhabitable the Caspian was a possession of but doubtful value. The first step making for security was to build a fleet strong enough to provide against the anarchical condition of those parts; but this implied a direct attack not only upon the Crimean khan, who was mainly responsible for the conduct of the Volgan hordes, but upon the khan's suzerain, the Turkish sultan. Nevertheless Peter did not hesitate. War against Turkey was resolved upon, and Azov, the chief Turkish fortress in those regions, which could be approached by water from Moscow, became the Russian objective. From the 8th of July to the 22nd of September 1695 the Muscovites attempted in vain to capture Azov. On the 22nd of November Peter re-entered Moscow. His first military expedition had ended in undistinguished disaster, yet from this disaster is to be dated the reign of Peter the Great.

Immediately after his return he sent to Austria and Prussia for as many sappers, miners, engineers and carpenters as money could procure. He did not want a fleet strong enough to prevent the Turkish fleet from relieving Azov. The guards and all the workmen procurable were driven, forthwith, in bands, to all the places among the forests of the Don to fell timber and work day and night, turning out scores of vessels of all kinds. Peter himself lived among his workmen, himself the most strenuous of them all, in a small two-roomed wooden hut at Voronezh. By the middle of April two warships, twenty-three galleys, four fireships and numerous smaller craft were safely launched. On the 3rd of May "the sea caravan" sailed from Voronezh, "Captain Peter Aleksyevich commanding the galley-flotilla from the galley Principium," built by his own hand. The new Russian fleet did all that was required of it by preventing the Turks from relieving Azov by water; and on the 18th of July the fortress surrendered. Peter now felt able to advance along the path of progress with a quicker and a firmer step. It was resolved to consolidate the victory by establishing a new naval station at the head of the Sea of Azov, to which the name of Taganrog was given. But it was necessary to guarantee the future as well as provide for the present. Turkey was too formidable to be fought single-handed, and it was therefore determined to send a grand embassy to the principal western powers to solicit their co-operation against the Porte. On the 10th of March 1697 this embassy, under the leadership of Lefort, set out on its travels. Peter attached himself to it as a volunteer sailorman, "Peter Mikhailov," so as to have greater facility for learning ship-building and other technical sciences. As a political mission it failed utterly, the great powers being at that period far more interested in western than in eastern affairs. But personally Peter learnt nearly all that he wanted to know—gunnery at Königsberg, ship-building at Saardam and Deptford, anatomy at Leiden, engraving at Amsterdam—and was proceeding to Venice to complete his knowledge of navigation when the revolt of the strielly, or musketeers (June 1698), recalled him to Moscow. This revolt has been greatly exaggerated. It was suppressed in an hour's time by the tsar's troops, of whom only one man was killed. There was not a formidable engagement (Sept. 24, 1698). Peter on his return to Russia wreaked upon the captive musketeers was due not to any actual fear of these antiquated warriors, but to his consciousness that behind them stood the reactionary majority of the nation who secretly sympathized with, though they durst not assist, the rebels.

Peter's foreign tour had more than ever convinced him of the inherent superiority of the foreigner. Imitation had necessarily to begin with externals, and Peter at once fell foul of the long beards and Oriental costumes which symbolized the arch-conservatism of old Russia. On the 26th of April 1698 the chief men of the tsarom were assembled round his wooden hut at Probrzahrenskoye, and Peter with his own hands deliberately clipped off the beards and moustaches of his chief boyars. The ukas of the 1st of September 1698 allowed as a compromise that beards should be worn, but a graduated tax was imposed upon their wearers. The wearing of the ancient costumes was forbidden by the ukas of the 4th of January 1700; thenceforth Saxon or Magyar jackets and French or German hose were prescribed. That the people themselves did not regard the reform as a trifle is plain from the numerous rebellions against it. By the ukas of the 26th of December 1699 it was next commanded that henceforth the new year should not be reckoned as heretofore, from the 1st of September, supposed to be the date of the creation, but from the first day of January, anno domini.

The year 1700 is memorable in Russian history as the starting-point of Peter's long and desperate struggle for the hegemony of the north. He had concluded peace with the Porte (June 13, 1700) on very advantageous terms, in order to devote himself wholly to a war with Sweden to the end that Russia might gain her proper place on the Baltic. The possession of an ice-free seaboard was essential to her natural development; the creation of a fleet would follow inevitably upon the acquisition of such a seaboard; and she could not hope to obtain her due share of the trade and commercial power of the world if she was not herself able to establish trade relations with Russia. The Swedish government was in the hands of an untried lad of sixteen; and the fine fleets of Denmark, and the veteran soldiers of Saxony, were on the same side as the myriads of Muscovy. It seemed an easy task for such a coalition to wrest the coveted spoil from the young Charles XII.; yet Peter was the only one of the three conspirators who survived the Twenty-one Years' War in which they so confidently embarked during the summer of 1701. He was also the only one of them who got anything by it. Charles's "immersion in the Polish bog" (1702-1707), as Peter phrased it, enabled the tsar, not without considerable expense and trouble, to conquer Ingria and lay the foundations of St. Petersburg. In these early days Peter would very willingly have made peace with his formidable rival if he had been allowed to retain these comparatively modest conquests. From 1707 to 1709 the war on his part was purely defensive; Charles would not hear of peace till full restitution had been made and a war indemnity paid, while Peter was fully resolved to perish rather than surrender his "paradise," Petersburg. After Paltova (June 26, 1709), Peter, hitherto commendably cautious even to cowardice, but now pulped up with pride, rashly plunged into as foolishly an enterprise as ever his rival engaged in. The campaign of the Pruth (March to July 1711) must have been fatal to the
Towards the end of the reign the question of the succession to the throne caused the emperor some anxiety. His rightful heir, the Tsarevich Alexei, was the only son his first wife, Catherine, had left to him. Peter, son of the Tsarevich Alexei, a child of six; but Peter decided to pass him over in favour of his own beloved consort Catherine. The ustrar, or ordinance of 1722, heralded this unheard-of innovation. Time-honoured custom had hitherto reckoned primogeniture in the male line as the best title to the Russian crown; in the ustrar of 1722 Peter denounced primogeniture in general as a stupid, dangerous, and even unscriptural practice of dubious origin. The ustrar was but a preliminary step to a still more sensational novelty. Peter had resolved to crown his consort empress, and on the 15th of November 1723 he issued a second manifesto declaring that in the person of the hereditary heir to the imperial throne, he should have considered any explanation necessary demonstrates that he felt himself to be treading on dangerous ground. The whole nation listened aghast to the manifesto. The coronation of a woman was in the eyes of the Russian people a scandalous innovation in any case, and the proposed coronation was doubly scandalous in view of the base and disputable origin of Catherine herself (see Catherine I.). But Peter had his way, and the ceremony took place at Moscow with extraordinary pomp and splendour on the 7th of May 1724.

During the last four years of his reign Peter’s policy was predominantly Oriental. He had got all he wanted in Europe, but the anarchical state of Persia at the beginning of 1722 opened up fresh vistas of conquest. The war which lasted from May 1722 to September 1723 was altogether successful, resulting in the acquisition of the towns of Baku and Derbent and the Caspian provinces of Gilan, Mazzandaran and Astarabad. The Persian campaigns wore out the feeble health of Peter, who had been ailing for some time. A long and fatiguing tour of inspection over the latest of his great public works, the Ladoga Canal, during the autumn of 1724, brought back another attack of his paroxysms, and he reached Petersburg too ill to rally again, though he showed himself in public as late as the 16th of January 1725. He expired in the arms of his consort, after terrible suffering, on the 28th of January 1725.

Peter’s claim to greatness rests mainly on the fact that from first to last he clearly recognized the requirements of the Russian nation and his own obligations as its ruler. It would have materially lightened his task had he placed intelligent foreigners at the head of every department of state, allowing them gradually to train up a native bureaucracy. But for the sake of the independence of the Russian nation he resisted the temptation of taking this inviting but perilous short-cut to greatness. He was determined that, at whatever cost, hardship and inconvenience, Russia should be ruled by Russians, not by foreigners; and before his death he had the satisfaction of seeing every important place in his empire in the hands of capable natives of his own training. But even in his most sweeping reforms he never lost sight of the idiosyncrasies of the people. He never destroyed anything which he was not able to replace by something better. He possessed, too, something of the heroic nature of the old Russian bogatours, or demigods, as we see them in the skazi and the bulinai. His expansive nature loved width and space. No doubt this last of the bogatours possessed the violent passions as well as the wide views of his prototypes. All his qualities, indeed, were on a colossal scale. His rage was cyclonic: his hatred rarely stopped short of extermination. His banquets were orgies, his pastimes convulsions. He lived and he loved like one of the giants of old. There are deeds of which he make humanity shudder, and no man equally great has ever descended to such depths of cruelty and treachery. Yet it may generally be allowed that a strain of nobility, of which we occasionally catch illuminating glimpses, extorts from time to time an all-forgiving admiration. Strange, too, as it may sound, Peter the Great was at heart profoundly religious. Few men have ever had a more intimate persuasion that they were but instruments for good in the hands of God.
PETER II.—PETER

(KINGS OF SPAIN)

PETER II. (1715—1730), emperor of Russia, only son of the Tsarevich Alexias, was born on the 18th of October 1715. From his childhood the orphan grand duke was kept in the strictest seclusion. His grandfather, Peter the Great, systematically ignored him. His earliest governesses were the wives of a tailor and a vintner from the Dutch settlement; a sailor called Norman taught him the rudiments of navigation; and, when he grew older, he was placed under the care of a Hungarian refugee, Janos Zelkin, who seems to have been a conscientious teacher. During the reign of Catherine I. Peter was quite ignored; but just before her death it became clear to those in power that the grandson of Peter the Great could not be kept out of his inheritance much longer. The majority of the nation and three-quarters of the nobility were on his side, and when his uncle, the emperor Charles VI., through the imperial ambassador at St Petersburg, Razutin, persistently urged his claims, the matter was arranged between Menshikov, Osterman and Razutin; and on the 18th of May 1727 Peter II., according to the terms of the supposed last will of Catherine I., was proclaimed sovereign autocrat. The senate, the privy council and the guards took the oath of allegiance forthwith. The education of the young prince was wisely entrusted to the vice-chancellor Osterman. Menshikov, who took possession of Peter II. and lodged him in his own palace on the Vasily island, had intended to marry Peter to his daughter Maria; the scheme was frustrated by his fall (Sept. 21, 1727), but Peter only fell into the hands of the equally unscrupulous Dolgoruki, who carried him away from Petersburg to Moscow. Peter's coronation was celebrated at that city on the 25th of February 1728. He was betrothed to Catherine, second daughter of Alexix Dolgoruki, and the wedding was actually fixed for the 30th of January 1730; but on that very day the emperor died of small-pox.

PETER III. (1728—1762), emperor of Russia, only son of Charles Frederick, duke of Holstein-Gottorp, and of Anne, eldest surviving daughter of Peter the Great, was born at Kiel on the 21st of February 1728. In December 1741 he was adopted by his aunt, Elizabeth Petrovna, as soon as she was safely established on the Russian throne, and on the 18th of November 1742 was received into the Orthodox Church, changing his original name of Karl Peter Ulrich for that of Peter Fedorovich. On the 21st of August 1745, by the command of his aunt, he married the princess Sophia Augusta Frederick of Anhalt-Zerbst, who exchanged her name for that of Catherine Aleksyevna. The union between a prince who physically was something less than a man and a mentally less than a child, and a princess of prodigious intellect and an insatiable love of enjoyment, was bound to end in a catastrophe. But there is no foundation for the stories of Peter's neglect and brutality. It took the spouses five years to discover that their tastes were divergent and their tempers incompatible. Even when Peter III. succeeded his aunt on the 3rd of January 1762, he paid all the debts that Catherine had contracted without inquiring what they were for. On her birthday, in April, he made her a present of domains worth 160,000 a year, though he had already readjusted her establishment on a truly imperial scale. A great deal has been made of Peter's infidelity towards his consort; but the only one who really suffered from his liaison was the ugly, stupid and vixenish countess Elizabeth Vorontsova was the unfortunate emperor. So far from being scandalized by the juxtaposition of "Das Fräulein" in the Winter Palace, Catherine accepted it as a matter of course, provided that her own relations with the handsome young guardsmen, Gregory Orlov, were undisturbed. Nor was Peter's behaviour to his courtiers, the public, or any of his opponents better than what one might have expected. Peter, in fact, was too good-natured and inconsequent to pursue, or even premeditate, any deliberate course of ill treatment. No personal wrongs, but the deliberate determination of a strong-minded, capable woman to snatch the reins of government from the hands of a semi-imbecile, was the cause of Peter's overthrow, and his stupendous blunders supplied Catherine with her opportunity. Peter's foreign policy was the absolute reversal of the policy of his predecessor. He had not been on the throne for two months when he made pacific overtures to the wellnigh vanquished king of Prussia, whom he subsequently alluded to as "the king my master." Peter's enthusiastic worship of Frederick resulted in a peace (May 5) and then (June 19) in an offensive and defensive alliance between Russia and Prussia, whereby Peter restored to Prussia all the territory won from her by Russia during the last five years at such an enormous expense of men and money, and engaged to defend Frederick against all his enemies. This was followed up by a whole series of menacing rescripts addressed by Peter to the court of Vienna, in which war was threatened unless Austria instantly complied with all the demands of the king of Prussia. Finally he picked a quarrel with Denmark for not accepting as an ultimatum the terms to be submitted by Russia to a peace conference to meet at Berlin for the purpose of adjusting the differences between the two powers. On the 6th of July the Russian army received orders to invade Denmark by way of Mecklenburg. This advance was only arrested, when the opposing forces were almost within touch of each other, by the tidings that a revolution had taken place at St Petersburg, and that Peter III. was already a prisoner in the hands of his consort. The coup d'état of the 9th of July 1762 properly belongs to the history of Catherine II. (q.v.). Here only a few words must be said as to the mysterious death of Peter at the castle of Ropsha, to which he was removed immediately after the finding his cousin Peter had remained from the evening of the 9th to the afternoon of the 15th of July. At first Catherine and her counsellors could not make up their minds what to do with "the former emperor." Imprisonment in Schlüsselburg for life, or repatriation to Holstein, were proposed only to be rejected as dangerous. The Orlov's had even stronger motives than Catherine for suppressing the ex-emperor, for Gregory Orlov aspired to win the hand as well as the heart of his imperial mistress, and so long as Catherine's lawful husband lived, even in a prison, such a union would be impossible. The available evidence points to the irresistible conclusion that on the after- noon of the 18th of July 1762, Peter III., with his consort's connivance, was brutally murdered at Ropsha by Alexius Orlov. Theodore Baryatinski, and several other persons still unknown.

See R. N. Bain, Peter III., Emperor of Russia (London, 1902); V. A. Bilsasov, History of Catherine II. (Russ.), vol. i. (Berlin. 1900).

PETER (Pedro), the name of several Spanish kings.

Peter I., king of Aragon (d. 1104), son of Sancho Ramirez, the third in order of the historic kings of Aragon, belonged to times anterior to the authentic written history of his kingdom; and little is known of him save that he recovered Huesca from the Mahommedans in 1096.

Peter II., king of Aragon (1174—1213), son of Alphonso II. and his wife Sancia, daughter of Alphonso VIII. of Castile, was born in 1174. He had a very marked and curious personal character. As sovereign of lands on both sides of the Pyrenees, he was affected by very different influences. In his character of Spanish prince he was a crusader, and he took a distinguished part in the great victory over the Almohades at the Navas de Tolosa in 1212. But his lands to the north of the Pyrenees brought him into close relations with the Albigenses. He was a favourite of the troubadours, and in his ways of life he indulged in the laxity of Provençal morals to the fullest extent. We are told in the chronicle written by Desclot soon after his time,
PETER DES ROCHES

that Peter was only trapped into cohabiting with his wife by the device which is familiar to readers of Measure for Measure. In the year after the battle of Poitiers, Raimond de Tolosa took up arms against his father, Simon of Montfort, moved not by sympathy with the Albignenses, but by the natural political hostility of the southern princes to the conquering intervention of the north under pretence of religious zeal. His son records the way in which he spent the night before the battle of Muret with a cruelty of language which defies translation, and tells us that his father was too exhausted in the morning to stand at Mass, and had to be lifted into the saddle by his squires. Peter none the less showed the greatest personal valour, and his body, recognizable by his lofty stature and personal beauty, was found on the field after the rout (Sept. 12, 1213).

See Choses I. of Peter, translated by J. Forster (London, 1883); and Life and Times of James the First the Conqueror, by F. Darwin Swift (Oxford, 1894).

PETER III, king of Aragon (1236-1286), son of James the Conqueror, and his wife Yolande, daughter of Andrew II. of Hungary, was born in 1236. Having married Constance, daughter of Manfred of Beneventum, he came forward as the representative of the claims of the Hohenstaufen in Naples and Sicily against Charles, duke of Anjou. Peter began the long strife of the Angevins and the Hohenstaufens that was to last half a century. Conquering Sicily earned him the surname of "the Great." He rebelled an invasion of Catalonia undertaken by the king of France in support of Charles of Anjou, and died on the 8th of November 1285.

For the personal character of Peter III., the best witness is the Chronicle of Ramonde Muntaner—reprinted in the original Catalan by R. Lina, Litterarischer Verein in Stuttgart, vol. vii. (Stuttgart, 1874). A different version is the French by Buchon, Coll. des chroniques nationales (Paris, 1824-1828). See also O. Cartellieri, Peter von Aragon und die sizilischen Vesper (Heidelberg, 1904).

PETER IV., king of Aragon (d. 1387), son of Alphonso IV. and his wife Teresa d'Enteca, is known as "The Ceremonious" and also as "he of the dagger." He acquired the first title by the rigid etiquette he enforced, as one means of checking the excessive freedom of his nobles. The second name was given him because he wounded himself with his dagger in the act of cutting to pieces the so-called "charter of the Union," which authorised the rebellions of his nobles, and which he forced them to give up, after he had routed them at the battle of Epila in 1348. Of no man of the 14th century can it be more truly said that his life was a warfare on earth. He had first to subdue his nobles, and to reannex the Balearic Islands to the crown of Aragon. When he had made himself master at home, he had to carry on a long and fierce contest with his namesake Peter the Cruel of Castile, which only terminated when Henry of Trastamara succeeded, largely with Aragonese help, in making himself king of Castile in 1356. Peter succeeded in making himself master of Sicily in 1377, but ceded the actual possession of the island to his son Martin. He was three times married: to Mary, daughter of Philip of Evreux, king of Navarre; to Eleanor, daughter of Alphonso IV. of Portugal; and to Eleanor, daughter of Peter II. of Sicily, his cousin. The marriage of his daughter by his third marriage, Eleanor, with John I. of Castile, carried the crown of Aragon to the Castilian line when his male representatives became extinct on the death of his son Martin in 1410.

See Zarita, Anales de Aragon (Saragossa, 1616).

PETER, "the Cruel," king of Castile (1333-1369), son of Alphonso XI. and Maria, daughter of Alphonso IV. of Portugal, was born in 1333. He earned for himself the reputation of monstrous cruelty which is indicated by the accepted title. In later ages, when the royal authority was thoroughly established, there was a reaction in Peter's favour, and an alternative name was found for him. It became a fashion to speak of him as El Justiciero, the executor of justice. Apologists were found to say that he had only killed men who themselves would not submit to the law or respect the rights of others. There is this amount of foundation for the plea, that the chronicler Lopez de Ayala, who fought against him, has confessed that the king's fall was regretted by the merchants and traders, who enjoyed security under his rule. Peter began to reign at the age of sixteen, and found himself subjected to the control of his mother and her favourites. He was immoral, and unfaithful to his wife, as his father had been. But Alphonso XI. did not imprison his wife, or cause her to be murdered. Peter certainly did the first, and there can be little doubt that he did the second. He had not even the excuse that he was passionately in love with his mistress, Maria de Padilla; for, at a time when he asserted that he was married to her, and when he was undoubtedly married to Blanche of Bourbon, he went through the form of marriage with a lady of the family of Castro, who bore him a son and then deserted her. Maria de Padilla was only the lady of his household whom he never became quite tired. At first he was controlled by his mother, but emancipated himself with the encouragement of the minister Albuquerque and became attached to Maria de Padilla. Maria turned him against Albuquerque. In 1354 the king was practically coerced by his mother and the nobles into marrying Blanche of Bourbon, but deserted her at once. A period of turmoil followed in which the king was for a time overpowered and in effect imprisoned. The dissensions of the party which was striving to coerce him enabled him to escape from Toro, where he was under observation, to Segovia. From 1356 to 1366 he was master, and was engaged in continual wars with Aragon, in which he showed neither ability nor daring. It was during this period that he perpetrated the series of murders which made him odious. He confided in nobody save the Jews, who were his tax-gatherers, or the Mahommedan guard he had about him. The profound hatred of the Christians for the Jews and Mudjares, or Mahommedans settled among them, dates from the years in which they were the agents of his unbridled tyranny. In 1366 he was assailed by his bastard brother Henry of Trastamara at the head of a host of soldiers of fortune, and fled the kingdom without daring to give battle. Almost his last act in Spain was to murder Suarez, the archbishop of Santiago, and the dean, Penalvarez. Peter now took refuge with the Black Prince, by whom he was received the following year. But he disgusted his ally by his faithlessness and ferocity. The health of the Black Prince broke down, and he left Spain. When thrown on his own resources, Peter was soon overthrown by his brother Henry, with the aid of Bertrand du Guesclin and a body of French free companions. He was murdered by Henry in du Guesclin's tent on the 23rd of March 1369. His daughters by Maria de Padilla, Constance and Isabella, were respectively married to John of Gaunt, and Edmund, duke of York, sons of Edward III., king of England.

The great original but hostile authority for the life of Peter the Cruel is the Chronicle of the Chancellor Pero Lopez de Ayala (Madrid, Pater Lope de Ayala, Historia de Castilla, Hil. de Don Pedro I., roi de Castille (Paris, 1848).

(D. H.)

PETER DES ROCHES (d. 1238), bishop of Winchester under John and Henry III., and conspicuous among the foreign favourites to whom these sovereigns owed much of their unpopularity, was a Poitevin by extraction. He received the office of chamberlain towards the close of Richard's reign, and under Richard's successor became an influential councillor. In 1205, doubtless through John's influence, he was elected to the see of Winchester. His election was disputed but, on appeal, confirmed by Pope Innocent III., who honoured Peter by consecrating him in person. None the less, the new bishop stood by his royal patron during the whole period of the interdict. In 1213 he was made justiciar in succession to Geoffrey Fitz Peter. This promotion was justified by the fidelity with which Peter supported the king through the barons' war. At the battle of Lincoln (1217) Peter led a division of the royal army and earned some distinction by his valour; but he played a secondary part in the government so long as William Marshal held the regency. After Marshal's death (1219) Peter led the baronial opposition to Hubert de Burgh, with varying success. At first the justiciar was successful. In 1221 Peter mediated going on crusade; 1223-1224 saw his party broken up by Hubert's energetic measures and in 1227 he was himself dismissed from his office and
turned his back on England to join the crusade of the emperor Frederick II. He was absent from England until 1231; but in the meantime he increased his reputation also as a soldier and diplomatist. After the fall of De Burgh he kept in the background, but offices and honours were heaped on his dependants, especially on his nephew, Peter des Rievaulx, and other Poitvians. This foreign party triumphed over the revolt which was headed by Richard Marshal in 1233. But the primate, Edmund Rich, voiced the general feeling when he denounced Peter as a mischief maker, and demanded that he should be dismissed from court. The king complied, and threatened the bishop with charges of malversation. Peter was ever permitted to leave the country with a pardon (1232); he retired to Paris, to his home during the Fronde, and received efficient aid in a war with the citizens of Rome (1235) and in the next year returned without molestation to his see. He was invited to go as the king's envoy to the court of Frederick II., but refused, apparently on the score of ill health. His public reconciliation with De Burgh (1236), effected through the mediation of the papal legate, provided a dramatic close to his long rivalry, but had no political significance, since both were now living in retirement. Peter died in 1238, and was buried at Winchester. He was undoubtedly a man of a winning personality, a good diplomat and financier, a statesman whose unpopularity was due merely to his desire to free himself from the insularity of the Englishmen, against whom he moved in the interest of his monastery. But his name is associated with a worthless clique of favourites, and his first steps which were taken by Henry III. to establish a feeble and corrupt autocracy. See C. Petit Dutaillis, Vie et règne de Louis VIII. (Paris, 1894); Lecointre Duperré, Pierre des Roches (Pottiers, 1868); Stubbs's Constitutional History of England, vol. ii.; H. W. C. Davis, England under the Normans and Anarchy (1903); T. F. Tout in the Political History of England, vol. iii. (1903). (H. W. C. D.)

PETER LOMBARD (c. 1100-c. 1160), bishop of Paris, better known as Magister sententiarum, the son of obscure parents, was born about the beginning of the 12th century, at Novara (then reckoned as belonging to Lombardy). After receiving his education at Bologna, he removed to France, bearing a recommendation to Bernard of Clairvaux, who first placed him under Lotolf at Reims, and afterwards sent him to Paris with letters to Gilduin, the abbot of St Victor. He soon became known for his great abilities in obtaining a theological chair in the cathedral school. His famous text-book, the Sententiae, was written between 1145 and 1150. On the 26th of June 1159 he became bishop of Paris. The accounts of his bishopric are satisfactory. There is a charge that he was guilty of simony, having received his office through the favour of Philip, brother of Louis VII., his former pupil. The date of his death is uncertain. According to one account he died on the 20th of July 1160, and as Maurice de Sully became bishop that year the statement seems probable. Yet there is evidence for a later date, and he may have been set aside for simony.

His famous theological handbook, Sententiarum libri quatuor, is, as the title implies, primarily a collection of opinions of the fathers, "sententiae patrum." These are arranged, professedly on the basis of the apophthegms of Augustine, Lombard's favourite authority, that "omnis doctrina vel rerum est vel sigillorum," into four books. Of the first three books of the Sententiae, and the third of the incarnation, the work of redemption, and the virtues, and the fourth of the seven sacraments and eschatology. The Sententiae show the influence of Abelard, both in method and arrangement, but lack entirely the daring of Sic et Non. Compared with that book they are tame. Gratian's Concordia discordantium canonum, as he called his Decretum, was another strong influence, Lombard not only derived his theology from Gratian, but saw the importance of a systematic method of discussing the relations to the "sentences" of a Gandolph of Bologna (still unpublished) which has not been established. The most important thing in the book was its classification of the doctrine concerning the sacramental system, by the definite assertion of the seven sacraments, and the acceptance of a definition of sacrament, not merely as "sign of a sacred thing," but as itself "capable of conveying the grace of God." The sentences soon attained immense popularity, ultimately becoming the textbook in almost every theological school, and giving rise to endless commentaries, over 180 of these being written in English. In 1390 the theological professors of Paris agreed in the rejection of sixteen propositions taken from Lombard but their decision was far from obtaining universal currency.

Besides the Sententiae, Lombard wrote numerous commentaries (e.g. on the Psalms, Canticles, Job, the Gospel Harmony, and the Psalterium anglicanum, some of which still exist in MS. Glossae seu commentaria in psalmos Davidis, were first published at Paris in 1533.

His collected works have been published in J. Pigné's Petrolegia latina, Tome 191 and 192. See J. H. Dentilhac, Chartularium universitatis parisisiensis, Tome i. (Paris, 1889); Protoz, Pierre Lombard, son époque, sa vie, ses écrits, son influence (Paris, 1868); J. K. Rich, Petri Laurenzini in seiner Stellung zur Philosophie des Mittelalters (Leipzig, 1897); Harms, Domgangeschichte, Bd. iii. (1890; Eng. trans. 1894-1899); and the article in Herzog-Hauck's Realencyklopädie, Bd. xi. (Leipzig, 1902).

PETER OF AIGUEBLANCHE (d. 1268), bishop of Hereford, belonged to a noble family of Savoy and came to England in 1236 with his master, William of Savoy, bishop of Valencia, being in attendance on Eleanor of Provence, the bride of Henry III. A year or two later he is found residing permanently in England as a member of the king's court; before 1230 he was archdeacon of Salop, and in 1240 he was chosen bishop of Hereford. In 1255 Peter acted as Henry's principal agent in the matter of accepting the kingdom of Sicily from Pope Alexander IV. for his son Edmund, and his rapacious and dishonest methods of raising money for this foolish enterprise added not a little to the unpopularity which surrounded the king and his foreign favourites. When civil war broke out between Henry and his barons the bishop remained loyal to his master, and while residing, almost for the first time, at Hereford he was taken prisoner in May 1263. He was, however, released when the king and his enemies came to terms, and after a stay in France he retired to Savoy, where he died on the 27th of November 1268. See F. Mugnier, Les Savoyards en Anglétérie au XIIIe siècle et Pierre d'Aigueblanche (Chambry, 1890).

PETER OF BLOIS (Petrus Blesensis) (c. 1135-c. 1205), French writer, the son of noble Breton parents, was born at Blois. He studied jurisprudence at Bologna and theology in Paris, and in 1167 he went to Sicily, where he became tutor to the young king William II., and keeper of the royal seal (sigillarii). But he made many enemies and soon asked permission to leave the country; his request was granted and about 1170 he returned to France. After spending some time teaching in Paris and serving Rotrou de Perche, archbishop of Rouen, as secretary, Peter entered the employ of Henry II. of England about 1173. He quickly became archdeacon of Bath and soon afterwards chancellor, or secretary, to Richard, archbishop of Canterbury, and to Richard's successor, Baldwin, being sent on two occasions to Italy to plead the cause of these prelates before the pope. After the death of Henry II. in 1189, he was for a time secretary to his widow, Eleanor, in Normandy; he obtained the posts of dean of Wolverhampton and archdeacon of London, but he appears to have been very discontented in his later years.

He died some time after 12 March 1195. His title is clouded by another Peter of Blois, who in 1275 was archpastor of Caen, and who published a work in four books, De Iudicio ante mortem, which are preserved in several collections, including the Patrologia of J. P. Migne and the Historiae francorum scriptores of A. Duchesne. Of separate editions the least are those by Pierre de Gousainville (Paris, 1667) and J. A. Giles (Oxford, 1846-1857).

PETER OF COURTENAY (d. 1170), emperor of Germany (or Constantinople), was a son of Peter of Courtenay (d. 1183), and a grandson of the French king, Louis VI. Having, by his first marriage, obtained the counties of Nevers and Auxerre, he took
for his second wife, Yolande (d. 1219), a sister of Baldwin and Henry of Flanders, who were afterwards the first and second emperors of the Latin Empire of Constantinople. Peter accompanied his cousin, King Philip of France, on the crusade of 1212, fought against the Albigenses, and was present at the battle of Bouvines in 1214. When his brother-in-law, the emperor Henry, died without sons in 1216, Peter was chosen as his successor, and with a small army set out from France to take possession of his throne. Consecrated emperor at Rome, in a church outside the walls, by Pope Honorius III., on the 9th of April 1217, he borrowed some ships from the Venetians, promising in return to conquer Durazzo for them; but he failed in this enterprise, and sought to make his way to Constantinople by land. On the journey he was seized by the despot of Cyprus, Theodore Angelus, and, after an imprisonment of two years, died, probably by foul means. Peter thus never governed his empire, which, however, was ruled for a time by his wife, Yolande, who had succeeded in reaching Constantinople. Two of his sons, Robert and Baldwin, became in turn emperors of Constantinople.

PETER OF DUISBURG (d. c. 1326), German chronicler, was born at Duisburg, and became a priest-brother of the Teutonic Order. He wrote the Chronicon terrae Prussiae, dedicated to the grand-master, Werner of Orsln, which is one of the chief authorities for the history of the order in Prussia. There is a rhyming translation in German by Nicholas of Jeroschin, which, though against the original, is published in Bd. I. of the Scriptorium rerum prussiarum (Leipzig, 1861).

See M. Töpper, Geschichte der preussischen Historiographie (Berlin, 1853); and W. Fuchs, Peter von Duisburg und das Chronicon oliuense (Königsberg, 1884).

PETER OF MARICOURT (13th century), a French savant, to whom his disciple, Roger Bacon, pays the highest tribute in his opus tertium and other works. According to Bacon he was a recluse who devoted himself to the study of nature, was able to work metals, invented armour and assisted St. Louis in one of his expeditions more than his whole army. According to Emile Charles (Roger Bacon sa vie, ses ouvrages, ses doctrines, 1861), Peter of Maricourt is the Pierre Pétrarque (or Pélisson) de Maricourt (Méharicourt in Picardy), known also as Petrus Peregrinus of Picardy, one of whose letters, De magnete, is partly reproduced in Libri 1. Hist. des sciences mathématiques en Italie (1838), ii. 70-71, 487-505.

PETER OF SAVOY (c. 1203-1268), earl of Richmond, younger son of Thomas I. (Tommaso), count of Savoy, was born at Susa. After spending some years as an ecclesiastic he resigned his prelatures, and in 1234 married his cousin Agnes, daughter and heiress of Aymon II., lord of Faucigny. Accepting an invitation from the English king, Henry III., who had married his niece, Eleanor of Provence, Peter came to England in 1240, and was created earl of Richmond, receiving also large estates and being appointed to several important offices. During several visits to the continent of Europe Peter had largely increased his possessions in Vaud and the neighbourhood, and returning to England in 1252 he became associated with Simon de Montfort, retaining at the same time the king's friendship. Having been employed by Henry to negotiate with the pope and with Louis IX. of France, he supported Earl Simon in his efforts to impose restrictions upon the royal power; but, more moderate than many members of the baronial party, went over to Henry's side in 1260, and was consequently removed from the council. In 1263 he left England, and when his nephew, Boniface, count of Savoy, died in the same year he assumed the title of count of Savoy. This was also claimed by another nephew, Thomas; but Peter compelled the inhabitants of Turin to submit to him and secured possession of the county. He died on the 16th or 17th of May 1268, leaving an only child, Beatrice (d. 1310). Peter gave to the castle of Chillon its present form, and his name to the Savoy palace in London. He has been called le petit Charlemagne, and was greatly praised for his valour and his wisdom.

See L. Wurstemberger, Peter der Zweite, Graf von Savoyen (Zürich, 1859): F. Mugnier, Les Savoyards en Angleterre (Chambéry, 1890); and C. Bémont, Simon de Montfort (Paris, 1884).

PETER THE HERMIT, a priest of Amiens, who may, as Anna Comnena says, have attempted to go on a pilgrimage to Jerusalem before 1096, and have been prevented by the Turks from reaching his destination. It is uncertain whether he was present at Urban's great sermon at Clermont in 1095; but it is certain that he was one of the preachers of the crusade in France after that sermon, and his own experience may have helped to give fire to his eloquence. He soon leapt into fame as an emotional revivalist preacher: his very ass became an object of popular adoration; and thousands of peasants eagerly took the cross at his bidding. The crusade of the pauperes, which forms the first act in the first crusade, was his work; and he himself led one of the five sections of the pauperes to Constantinople, starting from Cologne in April, and arriving at Constantinople at the end of July 1096 before he joined the only other section which had succeeded in reaching Constantinople—that of Walter the Penniless; and with the joint forces, which had made themselves a nuisance by pilfering, he crossed to the Asiatic shore in the beginning of August. In spite of his warnings, the pauperes began hostilities against the Turks; and Peter returned to Constantinople, either in despair at their recklessness, or in the hope of procuring supplies. In his absence the army was cut to pieces by the Turks; and he was left in Constantinople without any followers, during the winter of 1096-1097, to wait for the coming of the princes. He joined himself to the three remaining sections of the pauperes, and, with a following which he seems to have collected, and marched with them through Asia Minor to Jerusalem. But he played a very subordinate part in the history of the first crusade. He appears, in the beginning of 1098, as attempting to escape from the privations of the siege of Antioch—showing himself, as Guibert of Nogent says, a "fallen star." In the middle of the year he was sent by the princes to invite Kerbogha to settle all differences by a duel; and in 1099 he appears as treasurer of the alms at the siege of Arca (March), and as leader of the supplicatory processions in Jerusalem which preceded the battle of Ascalon (August). At the end of the year he went to Laodicea, and sailed thence for the West. From this time he disappears; but Albert of Aix records that he died in 1151, as prior of a church of the Holy Sepulchre which he had founded in France.

Legend has made Peter the Hermit the author and originator of the first crusade. It has told how, in an early visit to Jerusalem, before 1096, Christ appeared to him in the Church of the Sepulchre, and bade him preach the crusade. The legend is without any basis in fact, though it appears in the pages of William of Tyre. Its origin is, however, a matter of some interest. Von Sybel, in his Geschichte des ersten Kreuzzuges, suggests that in the camp of the pauperes (which existed side by side with that of the knights, and grew increasingly large as the crusade told more and more heavily in its progress on the pursuers of the crusaders) some idolization of Peter the Hermit had already begun, during the first crusade, parallel to the similar glorification of Godfrey by the Lorrainers. In this idolization Peter naturally became the instigator of the crusade, just as Godfrey became the founder of the kingdom of Jerusalem and the legislator of the assizes. This version of Peter's career seems as old as the Chansons des chêfs, a poem which Raymond of Antioch caused to be composed in honour of the Hermit and his followers, soon after 1130. It also appears in the pages of Albert of Aix, who wrote somewhere about 1150; and from Albert it was borrowed by William of Tyre. The whole legend of Peter is an excellent instance of the legendary amplification of the first crusade—an amplification which, beginning during the crusade itself, in the "idolizations" of the different camps (idola castorum, if one may pervert Bacon), soon developed into a regular saga. This saga found its most piquant beginning in the Hermit's vision at Jerusalem, and there it accordingly began—alike in Albert, followed by William of Tyre and in the Chanson des chêfs, followed by the later Chanson d'Antioche.

The original authorities for the story of Peter the Hermit are:

for the authentic Peter, Anna Comnena and the Gesta Francorum;
PETER THE WILD BOY—PETER, EPISTLES OF

for the legendary Peter, Albert of Aix. The whole career of the Hermits has been thoroughly and excellently discussed by H. Hagenmeyer, Peter der Hermite (Leipzig, 1879). (E. Br.)

PETER THE WILD BOY (fl. 1725-1785), a Hanoverian imbecile of unknown parentage, who, having been found living wild in the woods near Hanover in 1725, was brought to England by George I., whose interest had been aroused in the unfortunate youth by a certain amount of curiosity and speculation concerning Peter was excited in London, and the craze was the subject of a biting satire by Swift, and of another entitled The Most Wonderful Wonder that ever appeared to the Wonder of the British Nation, which has been attributed to Swift and Arbuthnot; Defoe also wrote on the subject, and Lord Monboddo in his Origin and Progress of Language presents the idiot Peter as an illustration of his theory of the evolution of the human species. He lived to an advanced age, was seen by Lord Monboddo in 1782, and died in 1785.

PETER, EPISTLES OF, the two books of the New Testament traditionally ascribed to the Apostle Peter.

1 Peter

This epistle is addressed to "the elect who are sojourners of the Dispersion (Diaspora) in Pontus, Galatia, Cappadocia, Asia and Bithynia." The "Diaspora" was the name generally given to the Jews who had settled abroad. It suggests that the letter was intended for Jewish Christians in the Diaspora mentioned. But i. 14, 15; ii. 9, 10; iv. 3 point rather to Gentile Christians, and it is better to take this view, and interpret the "Diaspora" metaphorically as referring to the isolated position of Christians among the heathen. The general impression made by the epistle is that the central idea was to strengthen the courage of the recipients, who were likely to undergo persecution, and to enjoin on them conduct which would remove all reasonable excuse for thinking that Christianity ought to be regarded as a crime.

Ch. i. 3-12 is an introduction of praise to God that he had caused the recipients of the epistle to be born again to the living hope in a glorious salvation. The rest of the epistle may be divided into three parts: (a) i. 3-ii. 10, mainly hortatory injunctions to live holy lives in accordance with this new trust, and to grow up as God's people in communion with Christ; (b) ii. 11-iv. 6, particular directions as to the line of conduct to be pursued towards the Gentiles and toward one another, with special reference to the relations of slaves to masters, of wives and husbands to each other, and of Christians to one another; to the first of these a passage is appended dealing with the sufferings of Christ as an example (ii. 21-25), and then the question of public and private worth is considered. There is a close connexion between the first and last parts, and in suffering, in the light of the sufferings of Christ and the blessings given by them both to the living and to the dead; (c) iv. 7-11 of the same chapter, less cohesion. It begins with exhortations not to forget prayer and love, then the believers are warned to be careful not to suffer only as Christians, not as breakers of the laws. The elders and the younger men are reminded of their duties to the community and to one another. The whole is brought to a close with an exhortation to all to fight manfully against the devil.

Date and Authorship.—These two questions are so closely connected that they cannot be considered separately. The external evidence of tradition is that the epistle was written by St Peter. This can be traced back to Irenaeus (iv. 9, 2) and Clement of Alexandria (Strom., iii. 18, 110), and it is thought by many writers that St Peter iii. 1, even if it be not itself Peter, is good evidence that the writer regarded 1 Peter as apostolic. Evidence for its use, without mention of its name, may be found in Polycarp, but probably not in the other apostolic fathers (cf. The N.T. in the Apostolic Fathers, Oxford, 1905, p. 137). It is, however, possible that Papias made use of it. It is doubtful whether Justin Martyr used it, but probable that it was known to Theophilus of Antioch. It is not mentioned in the canon of Muratori. Thus external evidence, though unanimous in favour of the Petrine authorship, is not sufficient to settle the question. The internal evidence consists of (a) evidence bearing on the date in connexion with the persecution of Christians, (b) evidence establishing the relation of the epistle to other documents in early Christian history, and (g) evidence concerning St Peter personally.

(a) It is clear from 1 Peter i. 6, ii. 12, iv. 19, 9, that the epistle was written during a time of persecution. The question which is doubtful is to which persecution the description best applies. The traditional opinion was that the persecution referred to under Nero. But it has been argued that the Neroine persecution according to Tacitus (Ann. xv. 44) was not a persecution of Christians as such, but was rather the result of false accusation. But there is no proof that there was any persecution of Christians at this time in Rome to which the epistle refers; and it is difficult to explain the persecution in the provinces of Asia Minor. Therefore many critics have felt obliged to bring the epistle into connexion with the epistle of Pliny to Trajan, written c. 112, and asking for the procedure to be followed in trials of Christians. This is the most probable conclusion which implies organized persecution in the provinces in question, and therefore Holtzmann, Weizsäcker and others regard this as fixing the date of the epistle in the beginning of the 2nd century, and excluding the Petrine authorship. Against this view it may be argued that the epistle describes the beginning of persecution. The writer still hopes that Christians will not be obliged to suffer for "the name," and is clearly aware of false accusations of crime. On the other hand Pliny's letter implies a time when Christianity was in itself a crime and was recognized as such. Thus it is urged, probably correctly, that the epistle belongs to the beginning of a period of which Pliny's letter marks a later development, and we can only say that c. 112 is the terminus ad quem.

The terminus a quo is more difficult to find. We do not know with certainty when Christianity became a recognized offence, and scholars have urged various arguments. The most decisive is the view of Neumann, and then that of Holtzmann, that it was only in the persecution of Domitian that Christians were crucified. Therefore it is the case that under Domitian: Sir W. M. Ramsay believes that this attitude was one of the results of the Jewish War of 70, and ascribes it to Vespasian. The earliest date he adopts the Petrine authorship is almost excluded, and it is difficult to reconcile the traditional date of St Peter's martyrdom with Ramsay's theory.

(b) The relations of 1 Peter to other books in early Christian literature are shown in the following table:

</table>

From this table it is sufficiently plain that 1 Peter is closely connected with Romans, Ephesians, James, and Polycarp. The majority of scholars are agreed that in the case of Romans the dependence is on the side of 1 Peter, and in the case of Polycarp on the side of Peter. But there is also a connexion with Ephesians as the most likely one, though in the former case the general opinion favours the dependence of 1 Peter, in the latter case its priority. In England, however, the priority of James has been supported by Mayor and Hirt. In the light of the established use of Romans it is possible that 1 Peter also used other Pauline epistles and some scholars have seen special traces of the influence of 1 Cor, and Gal. (for a list of these cf. Holtzmann, Einleitung in das N.T., 3, p. 314). It has been argued that the use of the Pauline epistles is improbable for Peter, but this is a subjective argument which is not decisive.

(g) According to tradition Peter was martyred in Rome, and it is probable that this was in the Neronine persecution. If this be so, then the date is the terminus ad quem of the epistle. If Ramsay, however, thinks that Peter may have survived this persecution and suffered at the beginning of the persecutions which, he thinks, were initiated by the Flavian emperors (see Peter, St., § 5, 4 and 5).

The whole question of authorship and date is thus a complex of smaller problems, many of which do not seem to admit of any definite answer. If St Paul's epistle to the Ephesians be genuine, and it was really known to the writer of Peter, and if Peter himself was not martyred in 64, the theory of Petrine authorship demands that it was written by Peter between 59 and 64. On the Petrine hypothesis this is the most probable view. The weak point is that it assumes a great spread of Christianity in the provinces of Asia Minor outside the activity of Paul, and that the official persecution of Christians as such began throughout the Roman Empire under Nero, for neither of which is there
corroborative evidence. On the non-Petrine hypothesis a date is demanded some time before the letter of Pliny; this suits the internal evidence better than any possible on the Petrine hypothesis, but it fails to explain the really considerable and early evidence for the Petrine authorship, and necessitates some purely hypothetical suggestion, such as Harnack’s view that the epistle was originally anonymous, and that the opening and closing sentences (i. 1 sqq., v. 12 sqq.) were added between A.D. 150 and 175, perhaps by the writer of 2 Peter.

The Provenance of the Epistle.—This is defined in 1 Peter v. 13 as Babylon. It has sometimes been argued that this is Babylon in Mesopotamia, in which there were, until the time of Alexander, two Perses Caiaias, messiahs; but no good tradition connects St Peter with the evangelization of Mesopotamia, and this district would have had little in common with the Graeco-Roman world of Asia Minor. Another suggestion is that the Egyptian Babylon is meant (Old Cairo); but in the 1st century this was probably merely a fortress. Thus there is an overwhelming weight of opinion in favour of the view that Rome, the Babylon of Apocalyptic literature, is intended. This also agrees with the tradition in 2 Tim. iv. 11, which (cf. 1 Pet. v. 13) suggests that St Mark was in Rome.

Reception in the Canon.—1 Peter seems to have been the earliest of the Catholic epistles to obtain recognition. By the year 200 it was accepted everywhere except in two places—the church of Edessa, which did not receive the Catholic epistles until the 5th century, and, if the canon of Muratori is to be trusted, the church of Rome. It should, however, be noted that Zahn emends the text of the Muratorianum (rather violently) so as to include the epistle (see also Bible: New Testament Canon.)

The Theology of 1 Peter.—The simplicity of the theology is marked, and affords an argument for an early date. Jesus is the Messiah of whom the prophets had spoken. "Spirit of Christ" is identified with the spirit which was in them. His suffering for sin had rescued the elect, and was also an example for Christians to follow. After his death he preached to the "spirits in prison." The source of Christian life is on the one hand belief in God who raised the Messiah from the dead, and on the other hand baptism which "saves . . . through the resurrection of Jesus Christ." The members of the community are "a royal priesthood, a holy nation"—i.e. inherit the promises made to the Jews, but this inheritance is bound up with the strongly eschatological doctrine that Christians are strangers in the world, the end of which is at hand.

The Church Organization of 1 Peter.—This also is very simple and primitive. The closest based on the Jewish model. The leaders are called presbyters or elders, and their duty is to act as shepherds to the flock. Beyond this there is no sign of a developed organization: each is to act in accordance with the gift (charis) which he has received. The "trace of old order" apart from the service of the community or for teaching, as to which the only limitation given is "If any man speak let him speak as the oracles of God," i.e. probably, in accordance with the Old Testament.

2 Peter

This epistle may be divided into five parts. (1) The writer who describes himself as "Simon (var. lect. Symeon) Peter, a servant and apostle of Jesus Christ," exhorts his readers to become perfect in knowledge and virtue, so as to enter the kingdom of Christ (i. 3–11). (2) He then explains his desire once more to testify to the power of Jesus, and bases his testimony partly on his own experience in the Holy Mount (apparently a reference to the Transfiguration), and partly on the "word of prophecy" (i. 12–21). (3) The mention of prophecy leads him to deal with the destruction of false prophets, who are accused of false doctrine and immoral practices. In this section is incorporated almost the whole of the epistle of Jude (ii. 1–22). (4) He then discusses a special feature of the false teaching, viz. doubts thrown on the Parousia, the certainty of which for the future he defends (iii. 1–13). Finally he warns his hearers that they must be found spotless at the Parousia, and emphasizes the agreement of his teaching with St Paul’s (iii. 14–18).

The main object of the epistle is to be seen in the attack made on the false teachers, and in the defence of the certainty of the Parousia of the Lord.

Authorship.—The traditional view is that it was written by St Peter from Rome after 1 Peter. This view is however untenable for the following reasons. (1) The epistle is not quoted by any writer of the 2nd century, and Origen, who is the first to mention it as Petrine, admits that its authorship was disputed. (2) The style and language differ greatly from that of 1 Peter: this argument may however fairly be met by the suggestion that it is improbable that he wrote Greek with ease, and that he may have used a variety of amanuenses. (3) The growth of immorality and false teaching to which it witnesses seems irreconcilable with a very primitive period of church life. It has incorporated the greater part of Jude in a wholesale manner difficult to reconcile with apostolical authorship. (5) It seems to attribute a position of scriptural authority to the Pauline epistles, and this is improbable either in the mouth of Peter, or during the 1st century.

Any one of these arguments would be weighty by itself; in combination they form an irresistible cumulative argument against the Petrine authorship of 2 Peter.

Date.—If the Petrine authorship be abandoned, the terminus ad quem of the epistle is its use by Origen (or, just possibly, by Clement of Alexandria), and the terminus a quo is fixed by the considerations: (1) the activity of an immoral Gnosticism; (2) the attainment by the Pauline epistles of great authority, and their perversion by heretics; (3) the use made of the epistle of Jude.

It is difficult to define the exact date to which these indications point, but there is a general agreement that it must be sought in the 2nd century, and perhaps the decades immediately before and after the year A.D. 150 are the most probable.

Place of Origin.—There is hardly any evidence on this point: but the most probable place seems to be Egypt, as the letter has points of connexion with Philo, Clement of Alexandria and the Apocalypse of Peter, and seems first to have been used in the church of Alexandria. It should however be noted that Deissmann argues on lexical grounds in favour of Asia Minor (Bibel. Stud. pp. 277–284).

Relation to other Early Christian Documents.—The documents with which 2 Peter has the greatest affinities are the epistle of Jude, and the Apocalypse of Peter, of which a fragment was found in Akhmim in 1892 by M Bouriant. In each case the affinity is very close, and is capable of more than one explanation. Roughly speaking 2 Peter ii. reproduces Jude: it is possible therefore either that Jude is an epitome of 2 Peter or that the writer of 2 Peter used Jude. The former hypothesis has a few supporters, notably T. Zahn and Spitta, but most writers are emphatic in thinking that 2 Peter has incorporated Jude, and that 2 Peter is a development of Jude (see also supra). The connexion with the Apocalypse of Peter is more complicated: the evidence of a comparison between the two documents (which is made in full in F. H. Chase’s article in Hastings’s Dictionary of the Bible) is to show that either one document is dependent on the other, or both were written by the same person, or both come from the same circle. Of these theories there is least to be said for the dependence of the Apocalypse on 2 Peter, and perhaps most for the dependence of 2 Peter on the Apocalypse.

Reception in the Canon.—2 Peter was the last of the Catholic epistles to be accepted as canonical. It was first regarded as such in Alexandria, perhaps originally in connexion with the Apocalypse of Peter rather than with 1 Peter. Thence it passed into the canon used by the church of Constantinople, in the 4th century made its way into the Roman canon, and in the 6th was accepted last of all by the Syria church (see also Bible: New Testament Canon.)

Theology of 2 Peter.—The theology of the epistle is specially marked by two characteristics: its high Christology, and its eschatological character. Christ is referred to as "our God and Saviour," and the fatherhood of God is apparently only regarded as referring to the Divine Son. The work of Christ was the redemption of the elect, and this redemption awaits its consummation in the Parousia. This is the central point of the teaching of the epistle and is obviously directed against that of the false prophets. The writer looks forward to the destruction of the present world by fire,
when the wicked, whether angels or men, who have been reserved for judgment will be finally condemned, and a new era of happiness for the world.

Church Organization.—There is very little in 2 Peter which throws light on church organization. From his silence it would appear that the monarchical episcopate, which was a part of the church order in the first Christian centuries, was not the order to which the writer belonged, and perhaps the prophets were still the chief guides, but the argument from silence cannot be pressed. In any case the growth of false and immoral prophecy, which ultimately led to the monarchical episcopate, was a great effect of this order, was far advanced and was one of the reasons which led to the writing of the epistle.

PETERBOROUGH, a town and port of entry of Ontario, Canada, and capital of Peterborough county, situated 70 m. N.E. of Toronto, on the Otonabee river and the Grand Trunk and Canadian Pacific railways. Pop. (1901), 11,230. The five falls of the Otonabee at this point, with a total descent of 50 ft., furnish power for a large and increasing number of manufacturing establishments, whilst its canalization as part of the Trent canal gives communication with Lake Ontario and Georgian Bay. Peterborough has an electric railway, and contains important manufactures of electrical machinery and supplies, iron and steel bridges, agricultural implements and cordage, and produces woolen mills. PETERBOROUGH, a town and municipal and parliamentary borough of Northamptonshire, England, 76 m. N. from London by the Great Northern railway; served also by the London & North Western, Great Eastern and Midland railways. Pop. (1891), 25,171; (1901), 30,872. It is built chiefly along the river Nene, on the north side, and on the western border of the Fen country.

The cathedral of St Peter is the third church that has occupied the site; the first, founded under Penda, king of the Mercians, about 650, was entirely destroyed by the Danes in 870, and the second, founded in King Edgar's reign, was accidentally burnt in 1116. The present building, founded in the following year, stands almost exactly on the site of the former. The nave was consecrated on the 4th of October 1237. It embraces in all, however, eight periods of construction, and in no other building can the transition be better studied through the various grades of Norman to Early English, while the later addition is an admirable example of Perpendicular.

The erection proceeded as usual from east to west, and, while an increase in elegance and splendor into the later parts, the character of the earlier buildings was so carefully kept in mind that no sense of incongruity is produced. A series of uniform decorated windows were added throughout the church in the 14th century, and their effect is rather to enhance than detract from the unity of design. The choir, early Norman, terminating in an apse, was founded in 1117 or 1118 by John de Sais or Sez, and dedicated in 1140 or 1143; the aisles of both transepts and the whole of the south transept were built by Martin of Bec, 1140-1150, and the remaining portions of the transepts and the central tower, of three stories, were completed by William de Waterville, 1155-1175; the nave, late Norman, was completed by Abbot Benedict, 1177-1193, who added a fourth story to the central tower; the nave, late Norman, by Abbot Andrew, 1193-1200; the western front, actually a vast portico of three arches, the unique feature of the building, and one of the finest specimens of Early English exteriors, must have been built between 1200 and 1250, during which period there were several abbots; but there exists no record of its reconstruction. The lady chapel, built parallel with the choir by William Parys, prior, was consecrated in 1290; the bell-tower was erected in the same century, 1274; the spire, the pinacles of the flaming tower of the west portal, and the enlargement of the windows of the nave and aisles were the work of Henry de Morcot in the beginning of the 14th century; the "new build" of the central tower in the Perpendicular style, begun in 1438, was not completed till 1528. In 1541 the church was converted into a cathedral, the abbot being made the first bishop. The extreme length of the building is 471 ft., and of the nave 211 ft., the breadth of the west front being 156; the height of the central tower in the 14th century, was 150, that of the spires and tower of the west front is 156 ft. In 1643 the building was restored by the solicitor-general, the grandson of the obelisk near the brasses and monuments, burnt the ancient records, levelled the altar and screen, defaced the windows, and demolished the cloisters. To obtain materials for repairs the lady chapel was taken down. In the latter part of the 18th century the church was repaired. In 1831 a throne, stalls and choir-screen were erected and other restorations completed. On account of the insecure state of the central tower in 1883 it was taken down; and its reconstruction, costing £15,000, was completed in 1898. The choir was reopened in 1889 after being closed, for thorough restoration, for six years.

Another important restoration of the west front and other parts was begun in the face of considerable adverse criticism; but the work was carried on with the utmost care. During the carrying out of this work many interesting discoveries were made, the most important of which was the discovery of the charnel-house, or charcoal-house, under the south transept. Catherine of Aragon was interred in the cathedral in 1536, and Mary Queen of Scots in 1587, but the body of the Scottish queen was removed to Westminster Abbey in 1612. Both interments were superintended by Robert Scarlett the sexton, commonly known as "Old Scarlett," whose portrait, a copy of the original, hangs in the west transept. He died in 1594 at the age of 98. Of the minstrels, the buildings there are some interesting remains. The cathedral is approached by a Norman gateway, above which is the chapel of St Nicholas, built by Abbot Benedict, and now used as the music school, and on the left of the chapel of St Thomas of Canterbury, partly built by Abbot John de Waterville, but originally Norman. The gateway to the bishop's palace, formerly the abbots' house, was built by Abbot Godfrey de Crowland in 1316, and the deanery gate by Abbot Kirton about 1280. One of the canons' houses is formerly a half of the 13th century.

Peterborough is included for civil purposes in the parish of St John the Baptist, but for ecclesiastical purposes it is divided into four additional parishes being St Mary's Boongate (1857), St Mark's (1858) and St Paul's (1866). The old parish church of St John originally stood to the east of the cathedral, but was rebuilt on its present site in the centre of the city (1401-1407) in Perpendicular style. The educational establishments include the Henry VIII. grammar or charter school, which used the church of St Thomas à Becket until 1883; the St Peter's training college for schoolmasters for the dioceses of Peterborough, Ely and Lincoln, erected from designs of Sir Gilbert Scott (1864); and Deacon's and Ireland's charity school, established in 1721 for the clothing and educating of twenty poor boys. The principal public building is the market house (1802), used as a "ladies' library". The fire and police of the town are chiefly due to the trade caused by the junction of so many railway lines. Adjoining the town are extensive woods and shews connected with the Great Northern and Midland railways. The principal manufacture is that of agricultural implements. The parliamentary borough returns one member (since 1885). The municipal borough, incorporated in 1874, is under a mayor, 6 aldermen and 18 councillors. Area, 1878 acres. The soke or liberty of Peterborough, with a population of 41,122, constitutes a separate administrative county (1888). The diocese of Peterborough includes the whole of Rutland, nearly all Leicestershire and Northamptonshire, and small portions of Derbyshire and Huntingdonshire.

Peterborough (Burgh, Burgus sancti Petri) is proved by its original name Medehamstede to have been a Saxon village before 655 when Saxulf, a monk, founded the monastery on land granted to him for that purpose by Penda, king of Mercia. Its name was altered to Burgh between 902 and 1005 after Abbot Kenulf had made a wall round the minister, but the town does not appear to have been a borough until the 12th century. The burgesses received their first charter from "Abbot Robert," probably Robert of Sutton (1262-1273). Until the 19th century the dean and chapter, who succeeded the abbot as lords of the manor, appointed a high bailiff, and the mayor and other officers were elected at the court leet of the town, which was incorporated in 1574 under the government of a mayor, 6 aldermen and 18 councillors. Among the privileges claimed by the abbot as early as the 13th century was that of having a prison for felons taken in the soke and borough. In 1576 Bishop Scambell sold the lordship of the hundred of Nassabourgh, which is coextensive with the soke, to Queen Elizabeth, who
gave it to Lord Burghley, and from that time until the 19th century he and his descendants, marquesses of Exeter, had a separate goal in Peterborough for prisoners arrested in the soke. The trades of weaving and wool-combing were carried on in Peterborough in the 14th century. The abbey formerly held four fairs, of which two, one called St Peter's fair, granted in 1180 and now held on the second Tuesday and Wednesday in July, and the other called the Bridge fair, granted in 1439 and held on the first Tuesday, Wednesday and Thursday in October, still survive and were purchased by the corporation from the ecclesiastical commissioners in 1876. Peterborough sent two members to parliament for the first time in 1547.

**Peterborough and Monmouth, Earl of**

*of (c. 1638–1735), English soldier and statesman, was born about 1638. His father, John Mordaunt, was created Viscount Mordaunt of Avalon and Baron Mordaunt of Reigate, Surrey, in 1639.*

He matriculated at Christ Church, Oxford, on the 11th of April 1674. When about sixteen years of age he joined Sir John Narborough’s fleet in the Mediterranean, and was appointed to the post of lieutenant in the flagship, the Prince Royal of Tripoli. His father died on the 5th of June 1675, and Charles Mordaunt succeeded to the peerage as Viscount Mordaunt. On his return from the second expedition to Tangier he plunged into active political life as a zealous Whig and an unsparing opponent of the duke of York. But his continued hostility to James II. forced him to repair to Holland in 1686, when he proposed to William of Orange to invade England. The disposition of the cold and cautious William had little in common with the fierce and turbulent Mordaunt. His plan was rejected, though the prudent prince of Orange deemed it judicious to retain his services. When William sailed to Torbay his friend accompanied him, and when the Dutch prince was safely established on the throne of England honours without stint were showered upon Lord Mordaunt. He was sworn of the privy council on the 14th of February 1689, on the 8th of April of the same year appointed first lord of the treasury, and a day later advanced in the peerage by creation as earl of Monmouth.

In less than a year he was out of the treasury, but he still remained by the person of his monarch and was with him in his dangerous passage to Holland in January 1691. He was one of the eighteen peers who signed the protest against the rejection, on the 7th of December 1692, of the motion for the appointment of a committee to inquire into the conduct of his uncle, the earl of Peterborough, by the death of his uncle Henry Mordaunt, and earl.

The four years after his release from the Tower were mainly passed in retirement, but on the accession of Anne he plunged into political life again with avidity. His first act was to draw down on himself in February 1702 the censure of the House of Commons for the part which he took in the attempt to secure the return of his nominee for the borough of Malmesbury. Through the fear of the ministry that his restless spirit would drive him into opposition to its measures if he stayed at home, he was appointed early in 1705 to command an expedition of English and Dutch troops in Spain. He was created the sole commander of the land forces in April 1705 and joint-commander with Sir Cloudesley Shovel of the fleet on the 1st of May, after he had been reinstated a member of the privy council on the 29th of March. He arrived at Lisbon on the 20th of June 1705, sailed for Barcelona (Aug. 1705) on an expedition for the conquest of Catalonia, and began to besiege that town. For some weeks the operations were not prosecuted with vigour and Peterborough urged that the fleet should return to Italy, but the energetic counsels of the Archduke Charles at last prevailed and by the 14th of October the city fell into his hands. On the 24th of January 1706 he entered Valencia in triumph, but these movements had weakened the garrison at Barcelona, which was now besieged by a superior French force under Téssé. The garrison, commanded by the archduke, defended their positions with great bravery, but would have been obliged to surrender had not the fleet of Sir John Leake, answering the appeals of Charles but contrary to the original orders of Peterborough, come to their assistance on the 8th of May, whereupon the French raised the siege on the 11th of May. It is difficult to understand the action of Peterborough in the conduct of the war, but when we consider that he was out of sympathy with the movement for placing an Austrian prince on the throne of Spain. When Charles determined upon uniting with Lord Galway’s troops and marching to Madrid, the advice of Peterborough again hindered his progress. At first he urged an advance by Valencia as supplies had there been collected, then he withdrew this statement; afterwards he delayed for some weeks to join Galway, who was in need of succour, but ultimately reached the camp on the 6th of August. The leaders of the army differed in their views, and Lord Peterborough was recalled to England to explain his conduct (March 1707).

On his return to England in August he allied himself with the Tories, and received his reward in being contrasted, much to his advantage, with the Whig victor of Blenheim and Malplaquet. The differences between the three peers, Peterborough, Galway and Tyrawley, who had served in Spain, formed the subject of angry debates in the Lords, when the majority declared for Peterborough; after some fiery speeches the resolution that he had performed many great and eminent services was carried, and votes of thanks were passed to him without any division (January and February 1708). His new friends were not desirous of detaining him long on English soil, and they sent him on a mission to Vienna, where he characteristically engaged the ministry by pledges of which they disapproved. He returned to England the next year, but the disappointment was softened by the command of a cavalry regiment, and by his appointment as a Knight of the Garter (Aug. 3 and 4, 1713). With the accession of George I. Lord Peterborough’s influence was gone. Worn out with suffering, he died at Lisbon on the 25th of October 1735. His remains were brought to England, and buried at Turvey in Bedfordshire on the 21st of November.

Lord Peterborough was short in stature and spare in habit of body. His activity knew no bounds. He was said to have seen more kings and postillions than any man in Europe, and the whole point of Swift’s lines on “Mordaunt” consisted in a description of the speed with which he hastened from capital to capital. He was eloquent in debate and intrepid in war, but his influence in the senate was ruined through his inconsistency, and his vigour in the field was wasted through his want of union with his colleagues. His first wife, Carey, daughter of Sir Alexander Fraser of Dores, Kincardineshire, died on the 13th of May 1709, and was buried at Turvey. Some years later (1722) he secretly married Anastasia Robinson (c. 1695–1753), a famous dramatic singer (from 1714) of great beauty and sweetness of disposition, daughter of Thomas Robinson (d. 1722), a portrait painter; but she was at first unrecognized as his wife, and lived apart from him (regarded merely as his mistress) with her two sisters at Parson’s Green. She remained on the operatic stage, till 1724. It was only a few months before his death that (after a second marriage ceremony) she
was introduced to society as the countess of Peterborough. He had a son John (1681–1710) who predeceased him, and was therefore succeeded in the title by his grandson Charles (1710–1779), whose son Charles Henry (1735–1814), 5th earl, died unmarried, the honours becoming extinct, except for the barony of Mordaunt, which passed to a collateral branch and fell into abeyance in 1836.

Bibliography.—The best accounts of the career of Peterborough are in the life by William Stebbing (1800), and the War of the Succession by Colonel John Arthur Parnell (1862). The earlier lives are founded on the writings of Captain Carleton (1728), which was analysed by Colonel Parnell, and dismissed as a fictitious narrative inspired by Swift, in the Eng. Hist. Rev. (1861), vi. p. 141.

PETERHEAD, a municipal and police burgh, and seaport of Aberdeenshire, is the most easterly town in Scotland. Pop. (1901), 11,794. It is situated about 33 m. by road E.N.E. of Aberdeen and 444 m. by rail, via Maud Junction, on the Great North of Scotland railway, from which there is a branch line. The town is built of the granite for which it is famous, and the quarrying of which for home and foreign use constitutes an important industry. Among the principal buildings are the town-house and town hall, of which the latter was completed in 1788, with a spire 125 ft. high, and the Arbuthnot museum and art gallery. In front of the town-hall is a statue to Field Marshal Keith (born at Inverugie Castle, 2 m. north-west, in 1666), which was presented to the burgh in 1868 by William I. of Prussia, afterwards German emperor. Peterhead is one of the Elgin district group of parliamentary burghs, with Banff, Cullen, Elgin, Inverurie and Kintore. It formerly had an extensive trade with the ports of the Baltic, the Levant and America, and was once a sub-port to Aberdeen, but was made independent in 1832. It was also for a long period the chief seat of the Greenland trade, but the Arctic seal and whale fishery is now extinct. The north and south harbours lie between the town and Keith Insh—a suburb at the extremity of the peninsula on part of which the town is built—and the isthmus dividing them is pierced by a canal crossed by an iron swing-bridge. In the north harbour are two graving docks. A third harbour has been built, the area of the three basins amounting to 21 acres. In addition to the granite quarrying and polishing, the leading industries are ship- and boat-building, agricultural implement works and woollen manufactures. The herring fleet possesses more than 600 boats and the annual catch averages nearly £200,000. About a mile to the south is the convict prison for Scotland. Since 1886 the prisoners have been employed upon the construction of a vast harbour of refuge, for which the breakwater extends from Boddam Point northwards across the bay. This great undertaking (intended to be completed in 1921) was designed by Sir John Coode (d. 1892). Peterhead is the terminus of a cable to Norway. About 6 m. south of Peterhead are the famous Bullers, or Roarers, of Buchan, an enormous rocky cauldron into which the waves pour through a natural arch of granite, with incredible violence, in a storm.

The town and lands belonged of old to the Abbey of Deer, built in the 13th century by William Comyn, earl of Buchan; but when the abbey was erected into a temporal lordship in the family of Keith the superiority of the town passed to the earl marischal, with whom it continued till the forfeiture of the earldom in 1716. The town and lands were purchased in 1720 by a fishing company in England and, on their failure, by the Merchant Maidens’ Hospital of Edinburgh for £3,000, who are still the owners. Peterhead, made a burgh of barony in 1593 by George Keith, fifth earl marischal, was the scene of the famous Battle of Grays Inn Close on Christmas Day 1715.

PETERS, or PEETER, HUGH (1595–1666), English Independent divine, son of Thomas Dykewoode, alias Peters, descended from a family which had quitted the Netherlands to escape religious persecution, and of Martha, daughter of John Treffry of Treffry in Cornwall, was baptized on the 29th of June 1598, and was educated at Trinity College, Cambridge. Having experienced conversion, he preached in Essex; returning to London he took Anglican orders and was appointed lecturer at St Sepulchre’s. He entertained, however, unorthodox opinions, and eventually left England for Holland. He visited Gustavus Adolphus in Germany about 1632, and afterwards became the minister of the English church at Rotterdam. Here his unorthodox leanings again attracted attention, and Peters made a further move to New England. He was connected with John Winthrop through his wife, and had already formed several friendships with the American colonists. He arrived at Boston in October 1635 and was given charge of the church at Salem. He took a leading part in the affairs of the colony, and interested himself in the founding of the new colony in Connecticut. In 1641 he returned to England as agent of the colony, but soon became involved in the political troubles which now began. He became chaplain to the forces of the adventurers in Ireland, and served in 1642 in Lord Forbes’s expedition, of which he wrote an account. On his return he took a violent part in the campaign against Laud, and defended the doctrines of the Independents in a preface to a tract by Richard Mather entitled “Church Government and Church Covenant discussed ...” (1643). He gained great reputation as a preacher by his discourses and exhortations at public executions, and as army chaplain. In the latter capacity he accompanied Lord Warwick’s naval expedition to Lyme in 1642 and Fairfax’s campaigns of 1645 and 1646, when his eloquence is said to have had a marvellous effect in inspiring the soldiers and winning over the people. At the conclusion of the war, Peters, though greatly disliked by the Presbyterians and the Scots, had attained great influence as leader of the Independents. In his pamphlet “Last Report of the English Wars” (1646) he urged religious toleration, an alliance with foreign Protestants, and an active propagation of the gospel. In the dispute between the army and the parliament he naturally took the side of the former, and after the seizure of the King by the army in June 1649 had interviews with Charles at Newmarket and Windsor, in which he favourably impressed the latter, and gave advice upon the best course to pursue. He performed useful services in the second Civil War, procured guns for the besiegers at Pembroke, raised troops in the midlands, and arranged the surrender of the duke of Hamilton at Uttoxeter. Though at the Restoration he denied any complicity in the king’s death, it is certain that in his sermons he justified and supported the trial and sentence. In August he accompanied Cromwell to Ireland, and was present at the fall of Wexford.
while later he assisted the campaign by superintending from England the despatch to Cromwell of supplies and reinforcements, and was himself destined by Cromwell for a regiment of foot. In 1659 he was in South Wales, endeavouring to bring over the people to the cause, and subsequently was present at the battle of Worcester. At the conclusion of the war Peters was appointed one of the preachers at Whitehall and became a person of influence. Parliament had already voted him an annuity of £200, and Laud's library or a portion of it had been handed over to him in 1644. He was one of the committee of twenty-one appointed to suggest legal reforms, and he published his ideas on this subject, which included a register of wills and land titles and the destruction afterwards of the ancient records, in his tract, "Good Work for a Good Magistrate" (1651), answered by R. Vaneon and Prune. He strongly disapproved of the war with Holland, and his interference brought upon him some sharp reprimands. In July 1658 he was sent to Dunkirk to provide apparently for the spiritual wants of the garrison. He preached the funeral sermon on Cromwell, and after the latter's death took little part in political events, though strongly disapproving of the removal of Richard. He met Monck at St Albans on the latter's march to London, but met with no favour from the new powers, being expelled from his lodgings at Whitehall in January 1660. On the 11th of May his arrest was ordered. On the 18th he succeeded in escaping from the Act of Indemnity and apprehended on the end of September at Southwark. He sent in a defence of himself to the Lords, denying any share in the king's death. He was, however, tried on the 13th of October and found guilty of high treason. His execution took place at Charing Cross on the 16th of October, when he behaved with great fortitude, and was undismayed by the mangeling of the body of John Cook, his fellow sufferer, upon which he was forced to look. Before his death he wrote "A Dying Father's Last Legacy" to his only child, Elizabeth, in which he gave a narrative of his career. His death was viewed with greater rejoicings than perhaps attended that of any of the regicides, which is the more surprising as Peters possessed many amiable qualities, and several acts of kindness performed by him on behalf of individual Royalists are recorded. But he had incurred great unpopularity by his unrestrained speech and extreme activity in the cause. He was a man, however, of a rough, coarse nature, without tact or refinement, of strong animal spirits, undeterred by difficulties which beset men of higher mental capacity, whose energies often outran his discretion, intent upon the realities of life and the practical side of religion. His conception of religious controversy, that all differences could be avoided if ministers could only pray together and live together, is highly characteristic of the pathos and at the same time the limits of his intellectual imagination. Peters married (1) Elizabeth, daughter of Thomas Cooke of Pebmarsh in Essex and widow of Edmund Read, and (2) Deliverance Sheffield, by whom he had one daughter, Elizabeth.

**PETERS, KARL (1856- ),** German traveller in Africa, one of the founders of German East Africa, was born at Neuhausen on the Elbe on the 27th of September 1856, the son of a Lutheran clergyman. He studied at Göttingen, Tübingen and Berlin, and in 1879 was awarded a gold medal by the Berlin University for his Frieden zu Venedig. After visiting London to study English principles of colonization, he returned to Berlin and promoted the German Colonization Society (Deutsche Kolonialverein). In the autumn of 1883 he proceeded with two companions to East Africa, and concluded in the name of his society treaties with the chiefs of Usengwa, Nguru, Usagara and Ukami. Returning to Europe early in 1883, he formed the German East Africa Company, which speedily obtained an imperial charter. The story of this enterprise, the first step in the formation of a German colony in East Africa, is told under **AFRICA, § 5.** In 1888 Peters undertook an expedition from the east coast of Africa, avowedly for the relief of Emin Pasha. This expedition was not sanctioned by the German government and was regarded by the British authorities as a filibustering exploit. One of its objects was to extend the sphere of German influence, and, reaching Umba early in 1890, Peters concluded a treaty with the king of that country in favour of Germany. He left Germany hastily on the approach of a representative of the British East Africa Company, and on reaching Zanzibar learned that his treaty was useless, as an agreement had been come to between Germany and Great Britain whereby Umba was left in the British sphere. On his return to Germany Peters was received with great honours, and in 1891 published an account of his expedition entitled *Die deutsche Emin Pasha Expedition,* which was translated into English. In 1891 he went out again to East Africa as imperial high commissioner for the Killimanjaro district, and under his administration he was in 1890 invested with the commission for delimiting the Anglo-German boundary in that region. In June 1892 accusations were brought against him of excesses in his treatment of the natives, and after three investigations had been held he was, in 1897, deprived of his commission for "misuse of official power." (He was regranted his title of imperial commissioner in 1906.) During 1893-1895 Peters was employed in the colonial office at Berlin. In 1896 he removed to London, where he occupied himself in schemes for exploiting parts of Rhodesia and Portuguese East Africa. In the interests of a company he formed, Peters explored the Fura district and Macombe's territory, and in 1899 he discovered ruins of ancient cities and deserted gold mines. He returned in 1901 and gave an account of his explorations in *The Eldorado of the Ancients* (1902). In 1905 he again visited the region between the Zambezi and Zambesi rivers.

Besides the books already mentioned and some smaller treatises Peters published a philosophic work entitled *Willenswelt und Welt-""(1883), and a dissertation on early gold production entitled *Das goldene Ophir Salomos* (1895), translated into English in 1898.

**PETERSBURG,** a city and port of entry of Virginia, U.S.A., on the Appomattox river, at the head of navigation, about 11 m. from its mouth, and 22 m. S. of Richmond. Pop. (1890), 22,680; (1900), 21,816; (1910), 24,127. It is served by the Atlantic Coast line, the Seaboard Air Line and the Norfolk & Western railways. The river, which is here spanned by two steel bridges and one frame bridge, is navigable to this point for vessels of 8 ft. draught at mean high water, and has been greatly improved by the Federal government, which in 1909 was engaged in deepening the whole channel to 12 ft. at mean high water and in excavating at Petersburg a new channel into which to deflect the river. In and about the city there is much of historic and scenic interest. At Blandford, a suburban hamlet, is the picturesque old Blandford church, erected about 1734. Petersburg has two public parks, and among its institutions the almshouse for aged poor (1848) and the almshouse for the insane (1886), an orphanage for girls and another for negroes, the state central hospital for the insane (negroes), the southern female college (non-sectarian, 1853), the university school for boys, the Bishop Payne divinity school (Protestant Episcopal) for negroes, and the Virginia normal and industrial institute (opened in 1883), also for negroes. There are two national cemeteries near Petersburg—Poplar Grove (about 4 m. south), containing about 6200 graves, and City Point (about 9 m. east), containing about 5100 graves; and in Blandford cemetery there are about 39,000 graves of Confederate dead. In this cemetery General William Phillips is buried, and there is a monument to Captain McRae, commander of the "Petersburg Volunteers," whose bravery in 1812-1813 prompted President Madison to call Petersburg the "Cockade City." The falls above the city furnish abundant water-power, and the city has various manufactures. The factory product was valued at $5,800,574 in 1905, 11-3% more than in 1900; in both 1900 and 1905 Petersburg ranked fourth among the cities of the state in the value of factory products. From Petersburg are shipped quantities of trunks and bags, peanuts, tobacco and cotton. In 1909 the foreign trade, wholly imports, was valued at $30,774. The city was formerly in Chesterfield, Dinwiddie and Prince George counties, but is now independent of county government.
An Indian village formerly stood on or near the site of the present city, and Fort Henry was built here by the whites in 1845. Petersburg was founded in 1733 by Colonel William Byrd (1674-1744) and Peter Jones, and was named (first Peter’s Point, and then Petersburg) in honour of the latter; in 1748 it was incorporated as a town. On the 25th of April 1781 a skirmish was fought in front of Petersburg between a British force of about 3000 under General William Phillips (1737-1781) and about one-third of that number of American militia under Baron Friedrich Wilhelm von Steuben; the Americans were defeated, and the British occupied the town. In the following month the British again entered Petersburg (General Phillips dying here on the 13th), but they were soon dislodged by Lafayette who subdued the town. General Winfield Scott was born near Petersburg, and practised law here for two years before he entered the army. Petersburg was chartered as a city in 1850.

Petersburg Campaign (1864-65). The name of Petersburg is associated with operations in the American Civil War, which formed the sequel of the Wilderness Campaign (q.v.) and the last act in the struggle between the armies of Grant and Lee for supremacy. Petersburg (see above) and Richmond, Virginia, were of great strategic importance. They were the key points on which the Confederacy depended. For forty-five miles of entrenchments, formed the salients of a vast fortress, into which reinforcements and supplies could be poured from the rear by means of the James Canal, the Virginia Central, the Lynchburg, the Danville and the Weldon railroads—the latter bringing up to Petersburg from Wilmington (225 m. distant) the cargoes of blockade runners. Petersburg became a strategic point as soon as Grant determined to carry the army of the Potomac—defeated at Cold Harbor on the Chickahominy (see WILDERNESS CAMPAIGN)—south of Richmond, and, being joined by Butler’s Army of the James (momentarily checked in the Bermuda Hundred Peninsula by a small army under Beauregard), to operate from the east, depending on the James river, as his line of supply, while the policy of the Confederate president was to employ Robert E. Lee’s army to protect his capital. Petersburg was nearer than Richmond to the navigable part of the James River—City Point is only 10 m. distant—and the capture of Petersburg would involve the fall of Richmond and the capitulation or flight of Lee’s army.

As early as the 9th of June 1864, while the main armies were still north of the James and Petersburg was garrisoned by a brigade under General Wise, a Federal expedition from the Army of the James approached the city. General Kautz of the City Point road discovered strong earthworks, and General Kautz attacking on the Jerusalem Plank road experienced a repulse; the total force of the Federals was 4500, and Wise’s brigade (2400) had been quickly reinforced from Beauregard’s central position at Bermuda Hundred. A week later a more serious attempt was made to break through the defences, while General Lee’s main army was detained north of Richmond. Grant detached the II. and XVIII. corps under Generals Smith and Hancock, who were to unite and operate along the City Point railroad and capture the outer line of works about 2 m. from Petersburg while a demonstration was made along the Norfolk railroad by cavalry under Kautz. On the 15th of June Smith attacked and captured five redans before Hancock came up, and when next day Burnside’s corps (IX.) arrived and General Meade assumed control of the three corps, he attacked again at 6 p.m. On the 17th of June Warren’s (V.) corps arrived, and Meade made a third assault with two corps (V., IX.). On the 18th of June the attack was renewed with three corps (II., V., IX.) late in the afternoon, and the results of the four days’ fighting were so far satisfactory that ground was won which could be entrenched and held against any sortie of the Petersburg garrison. Probably on the 18th of June the town of Petersburg might have been captured by Meade, for at this crisis General Lee was in temporary eclipse. Fort Hill on the James was occupied by the Federals, but Lee refused to credit any report to the effect that Grant was crossing the James: his cavalry could not ascertain that the enemy in his front at Malvern Hill (VI. corps and Wilson’s cavalry division), despite its menacing attitude towards Richmond, was only a flank guard for a movement to the south.

It was late on the 17th of June when General Beauregard, who had for three days valiantly held his main lines south of Richmond with some 14,000 infantry against three Federal corps, succeeded in convincing General Lee that the main army was again (as in 1862 on the Chickahominy) in the wrong place at the wrong time. But when at last the Confederate leader was aroused to a sense of his danger he soon filled every road with divisions marching to save Petersburg; they marched all night; they slept in the trenches on arrival, and on the 19th of June these reinforcements convinced General Meade that his main attack between the Appomattox river and the Jerusalem Plank road was delivered a day too late. At a cost of 10,000 casualties Meade had gained half a mile of ground, but the Confederates in falling back had concentrated, and now that the new plan of operations was exposed and the main bodies were again face to face the power of defensive tactics reassumed itself.

Yet June was not to close without adding some 8000 men to the Federal casualties, for in addition to daily losses by sharp-shooting along the front, over 5000 men fell or were captured in sorties, which were made against Petersburg and the railroads. Grant had resolved to deprive his enemy of these lines of supply: his plan was to prolong his line of investment westward and construct redoubts (such as Fort Davis, Fort Steadman and Fort Sedgwick) as a continual menace to the Confederate garrison and a defence against sorties, while his cavalry and portions of five corps (II., V., VI., IX. and XVIII.) engaged in enterprises which it was hoped would tempt General Lee to fight outside his works. A decisive victory in the field, a successful assault on the defences between Richmond and Petersburg, or the complete destruction of the railroads, would precipitate disaster to the South, and of these three methods the last would be the surest in its effects. But such a method was necessarily slow. General Wilson’s cavalry (3500) destroyed 30 m. of the Lynchburg or South Side railroad, and 30 m. of the Danville railroad, together with Burkesville Junction and Ream’s Station on the Weldon railroad; but Wilson was caught by the Confederate cavalry 100 m. from Petersburg and escaped only by destroying his wagons and limbers and abandoning twelve guns. Even the Virginia Central railroad could not be held by the Federals after Sheridan with the main body of the cavalry had been called back to White House on the Pamunkey to escort a great column.

By the end of June the whole of the rival forces were concentrated about the Richmond-Petersburg defences, and General A. P. Hill had already rallied out on the 21st of June to drive the II. corps from the Weldon railroad. Federal policy and Federal strategy, surrounding the crisis of Cold Harbor, were, however, at last in unison. Grant had a free hand in respect both of his dispositions and his resources in men and money, and had resolved to use unsparingly the resources placed at his disposal. Early in July Grant, however, found himself compelled to detach a corps (VI.) to strengthen the garrison at Washington, for General Early had frustrated Hunter’s attempt against Lynchburg (see SHENANDOAH VALLEY), driving Hunter into West Virginia, and then pushed down the Shenandoah and across the Potomac, had arrived within a day’s march of the Federal capital. This operation checked Grant’s enterprises about Petersburg and restricted the Federal front to the ground east of the Weldon railroad.

On the 25th of July Grant resolved to weaken the enemy on his front by a demonstration north of the James, and accordingly moved a corps (II.) and two cavalry divisions across the river to Malvern Hill under cover of Foster’s corps (X.). But Lee possessed the inner line, and the Federal detachment found two cavalry divisions in its front, and the Richmond defences had been strengthened by three divisions of infantry. The expedi- tion returned to take part in a fresh enterprise, which ended disastrously to the Federals. A Confederate redan faced Burnside’s IX. corps 100 yds. distant, and this strong work was
to be destroyed by mining operations. The mine was fired and produced a crater 150 ft. long, 60 ft. wide and 25 ft. deep, into which the Federals fell in another demonstration against Richmond was planned. But Lee again strengthened his left and the result of the fighting was a loss to the Federals of nearly 3000 men. Meanwhile another attack on the Weldon railroad by Warren's corps was met by General A. P. Hill, who, on the night of August 30th, and the possession of this railroad cost the Federals 3000 men. A further attempt on this railroad by Hancock's II. corps and Gregg's cavalry division at a point 3 m. south of Eay's Station was failed by A. P. Hill, now aided by two cavalry divisions, and the Federals here lost 2317 men and nine guns. The Confederates therefore still retained possession of the railroad to a point within one day's hauling by wagon to Petersburg. During September another Federal enterprise north of the James with two corps (X and XVIII.) resulted in the capture of Fort Harrison near Chaffin's Bluff, and when General Lee reinforced his left and counter-attacked his troops were repulsed with heavy loss. The Federals lost over 2000 men and failed in the attempts to take Fort Gilmer, Confederate gunboats below Richmond aiding in the defense. While this operation was in progress on the Confederate left under General Grant's personal supervision, General Lee was apprised of attacks on his extreme right at Peebles Farm by four divisions, which captured a Confederate redoubt covering the junction of two routes to the south-west. General A. P. Hill prevented a further advance of the enemy by a vigorous counter-attack which caused Warren and Parke's (IX) a loss of 2000 men, of whom nearly three fourths allowed themselves to be captured: for the rank, since the losses of the May battles, had been swamped by forced and substitute recruit of poor quality and almost insignificant training. The Federals had, however, by these operations pushed their entrenchments beyond the Weldon railroad westward and established new works within a mile of the Confederate right. A minor engagement north of the James on the 7th of October between the Confederates and the Army of the James was without result. At the end of the month, however, General Grant resolved to make a serious effort to bring the South Side railroad, and within lines and connected with its main line of supply. Parke's (IX), Warren's (V) and Hancock's (II) took each some 11,000 infantry with four days' rations on pack animals. Gregg's cavalry (3000) were attached for the operation, and both Grant and Meade accompanied the troops. General A. P. Hill encountered this force with three divisions (14,000) and Hampton's cavalry (5500), and he contrived to hold two corps with one division and attack Hancock's (II) with his main body. The Federals were stopped when 6 m. from the railway, and Hancock lost 1500 men at Hatcher's Run on the 27th of October.

General Lee meanwhile had been called to Chaffin's Bluff, where again Butler was demonstrating with the Army of the James (X and XVIII.) to the approaches to Richmond. But General Longstreet signaled his return to duty with the Army of Northern Virginia by driving Butler off with a loss of over 1000 men (action of Fair Oaks, Oct. 27). General Warren in December contrived to evade A. P. Hill and destroy the Weldon railroad at a point on the Meherrin river 40 m. from Petersburg.

There seemed now little to tie Lee to the lines he had so painfully constructed, for his army was without coffee, tea or sugar, and though of foreign meat they had 34 million rations and of bread 21 million rations in reserve, the troops lived chiefly on corn-bread. A. P. Hill on the right held on from Hatcher's Run to Fair Oaks, while Gordon and Anderson prolonged to the left as far as the Appomattox River, and Longstreet continued the line northwards along the Bermuda front across the James as far as White Oak Swamp (37 m. in all). The winter was very severe, and the continual trench-work and outpost duty overtaxed the patriotism of Lee's 50,000 infantry and stimulated desertions. Supplies were brought in by wagons, as the rolling stock on the railways was worn, and on the 5th of February 1865 General Gregg moved out to the Boydton Plank road to intercept the Confederate convoys. He was supported by Warren, while Humphreys's (II.) corps connected the detachment with the left of the Federal entrenchments. Gregg failed to locate the wagons, and General Lee, hearing of the expedition, sent out A. P. Hill and Gordon, who drove him back with a loss of 1500 men. Sheridan, after driving Early from the Valley in October, destroyed the railways about Staunton, Charlottesville, Gordonsville, and Lynchburg, and even rendered the James Canal useless as a line of supply.

Grant recalled Sheridan to the main army in March, and at the end of the month prepared for a turning movement westward with the object of drawing Lee out of his lines. General Lee had anticipated such an attempt, and had resolved to abandon his lines and unite with Johnston in North Carolina, but the roads were not
yet in a state for the movement of artillery and wagons, and it was to gain a time that he now ventured upon a bold offensive stroke—a night attack upon a strong point in the Federal right called Fort Steedman—by means of which might cause Grant to call in the detachments on his left and so facilitate the proposed movement of the Confederates towards Danville. General Gordon was selected to conduct this and his corps was strongly reinforced for the occasion. The opposing lines east of Petersburg were only 150 yds. and the sectors of each side 50 yds. apart. Gordon's men dashed across the intervening space at 4:30 a.m. on the 25th March, surprised the garrison and occupied Fort Steedman, but when daylight broke and the Federal guns could be brought to bear the fort was found to be untenable. Park's corps (IX) recaptured the work at a cost of 1000 men, and Gordon fell back, leaving nearly 2000 men in the hands of the Federals. The encounter would have proved a more desperate one if reinforcements on both sides had arrived in time, but Gordon had cut the telegraph which connected Fort Steedman with Grant's headquarters at City Point, and the Confederate train service broke down. Grant decided the deal from Richmond of reinforcements for Gordon. Meanwhile, 6 m. westward, Humphreys' corps (II.) attacked A. P. Hill's defences and gained some local success, seizing the Confederate picket line between the Weldon railroad and the Boydton Plank road, which was at once occupied and strengthened by the Federals. The Federals had resolved to attempt. Grant meanwhile had ordered Warren to support Sheridan in an attack on Pickett at daybreak. Sheridan advanced on the 1st of April and at 3 p.m. issued his orders for attack, explaining verbally a diagram he had prepared for the use of divisional commanders. Pickett held a front of 2 m. with a division of cavalry on either flank and Rosser's cavalry guarding the baggage behind Hatcher's Run, and when attacked at 4 p.m. he was with Rosser 15 m. in rear. Before Pickett was made aware of a battle being in progress his left was destroyed. General Lee seems to have made no arrangements to support Pickett in this direction. The right was defended by W. H. F. Lee against the attack of Custer's cavalry division. The position was finally carried by Sheridan's cavalry under Devin dismounting and storming the entrenchments frontally, taking three guns and 100 prisoners. Warren's corps claimed to have captured a battery and 3244 prisoners. Yet Sheridan was dissatisfied with Warren's conduct of the battle and deprived him of his command. Pickett's routed brigades were rallied at the South Side railroad and incorporated with General Anderson's command. But the Confederates had lost White Oak road, and unless General Lee was capable of a vigorous counterstroke on his extreme right it was evident he must also lose the South Side railroad. Grant, luring such an enterprise, at once reinforced Sheridan and ordered Humphreys' corps (II.) to attack in his front if necessary to prevent Lee moving troops westward, but Lee made no effort, and so Sheridan was free to operate farther in the direction of the enemy's right and rear, while Humphreys held the enemy in his front. Sheridan remained inactive for a few days, and Lee hoped still to gain time for the roads to be cleared of obstacles, to put wagon lines and removing his stores and ammunition by wagons towards Lynchburg.

But a crisis was approaching. Sheridan's success at Five Forks induced Grant to deliver a general assault on the 2nd of April. The Confederate lines were bombarded all night, and on the 2nd April with Wright's corps (VI.), Grant attacked the weakest part of Lee's line and broke through, losing 1100 men in fifteen minutes. A. P. Hill was killed and his corps broke and was cut off from Petersburg. At the same time Parke's corps (IX.), on the right of the VI., attacked the eastern front near Fort Steedman but was repulsed by General Gordon; then Humphreys' corps (II.) on the left attacked a Confederate division under General Cook and forced it to retreat to the South Side railroad, where at Sutherland Station a final attack dispersed it, Wright, supported by General Ord (commanding the army of the James), afterwards won the strong redoubts called Fort Griswold and Fort Gregg, and thus in a day the Confederate right had been destroyed from Five Forks to a point some two or three miles west of the Weldon railroad; 10 m. of works had been abandoned, and if Grant had been able to press his advantage at once the campaign must have ended. But Grant was now aware of the enemy's plight, and so resolved to wait until the morrow before completing his victory.

Meanwhile Lee perceived that the hour had come at last when Richmond must fall, and at 3 a.m. he issued orders for the march of the remains of his army to Lynchburg via Amelia Court-House, a march which evidently must partake of the character of a forlorn hope, hastily planned, ill prepared, and undertaken by troops whom the disasters and hardships of the past six months had weakened physically and morally. Yet if General Lee had negotiated a peace on the 2nd of April military history would have lost one of the finest examples of the strategic genius. Lee's proposed movement involved the transfer of the army and its baggage 100 m. in bad roads across the front of an enemy, and nothing but mischance could prevent the Federals intercepting Lee's columns by a shorter route and seizing the South Side railroad, on which supplies
were to be forwarded from Lynchburg to meet the retiring army at Appomattox Station, Pampkin's Station or Farmville Station. The Appomattox River must be crossed two or three times at its bends. Various creeks and swamps must be bridged, and the dilapidated crossings of the Richmond and Petersburg Railroad between the Appomattox and Goode's Bridge. Ewell from Richmond crossed the Appomattox by the Danville railroad bridge north of Goode's Bridge. Anderson commanded the flank guard which moved south of the track. Fitzhugh Lee crossed in two flanked-guard early on the 3rd of April near Nanzomzie Creek, and at nightfall the Federal advance-guard was at Deep Creek. On the 4th of April Sheridan reached the Danville railroad at Junction and on the 6th of April, when Lee had been at Amelia Court-House on the railroad to get supplies, the Federals had three corps (II. V., VI.) in support of Sheridan 8 m. nearer than Lee to Sailor's Creek, the point where he must again cross the Appomattox.

Intercession was now a fait accompli, though neither side suspected it. Lee was unaware of the enemy's proximity, and Grant believed that Lee would remain at Amelia Court-House, but Lee moved west, crossing Flat Creek about Sunday, 3d of April, to Goose Creek (Longstreet, marching all night, reached Rice's Station at sunrise on the 6th of April), while the Federals moved northwards on the same day to attack Lee at Amelia Court-House, and on discovering Lee's retreat to the north advanced on Beauregard. Lee was on the left and advanced on Deatonsville after bridging Flat Creek. Meanwhile the Federal cavalry under H. E. Davies had located a convoy on Painsville, driven near Rice's Station, and Lee had been in touch with the cavalry, which had been attacked by Fitzhugh Lee's cavalry at Amelia Springs and driven back on the main body at Flat Creek. Fitzhugh Lee had then marched to join Rice at Longstreet's Station. The rear-guard of Lee's army was Gordon's command, which was at Amelia Springs after Ewell's command had passed through at 8 a.m. on the 6th of April. Lee's army stretched out for 15 m., and when its advance-guard was at Rice's Station its rear-guard was still at Amelia Court-House 62 m. behind Lynchburg. Here Longstreet waited all day for Anderson, Ewell and Gordon to close up, and then at night he moved 8 m. to Farmville Station (68 m. south-west of Richmond), where 80,000 rations had been served at the Appomattox. The next day, 7th of April, he crossed the Appomattox, and on the 7th of April moved forward towards Lynchburg, covered by Fitzhugh Lee's cavalry. Meanwhile the remainder of Lee's army had been practically destroyed within a few miles of the point where Longstreet had halted. Sheridan's cavalry and two corps (II. V.) had caught the commands of Anderson, Ewell and Gordon, entangled with the trains of the army attempting the passage of Sailor's Creek; and General Ord would lose a third of his long-street (whom he had waited late at night) had his march been delayed.

Complete disorganization and demoralization seem to have taken hold of the Confederates. The sun set on this discomfiture, and General Lee's influence more in eclipse. The Federal cavalry headed the column, the infantry attacked it, and Ewell became the victim of tactical envelopment after Anderson had been defeated and Gordon had failed to make good the advance of the cavalry or the infantry. The alternatives, Ewell surrendered, and here in fact the career of the army of Northern Virginia ended, as Grant plainly saw; for at 5.30 p.m. he addressed a demand to Lee for his capitulation. But Lee clung to his diminished forces until the night of 9th. Longstreet in crossing at Farmville had burnt the bridges and thus delayed Ord in pursuit; but Gordon and Mahone, who had crossed at High Bridge (the railroad bridge), failed to check Humphreys' corps, which had compelled the cavalry to stop on the south side of the bridge. The infantry followed. Meanwhile Gordon with the cavalry (V.) had hastened on the South Side railroad, seizing the supplies waiting for Lee at Pamplin Station, and then moving on another 12 m. to Appomattox Station. At nightfall he found that he was astride the enemy's line of operation, where the arrival of supply of General Lee would be compelled to give battle or capitulate on the morrow.

General Lee, quitting Farmville heights on the night of the 7th of April changed the order of march during the next day, so that Gordon (50th) was on the right, demoralized and without a flank guard. Ewell's corps was now represented by 300 effectives. The cavalry still numbered some 1600 sabres. Lee's column was pursued along the Lynchburg Road by two Federal corps (II. V.), while Gordon reached the town by midnight. General Lee now moved out 3 m. of Longstreet, who had entrenched near Appomattox Court-House, facing east and covering the road on which Gordon's corps and the infantry were to follow on the left. But Gordon on the morning of the 9th of April found Sheridan's cavalry in his front, and in accordance with plans made overnight he commanded an attack, driving the Federals back until he encountered at 10 a.m. two corps of infantry (V., XXIV.) under General Ord, who had marched 29 m. in order to support Sheridan at the crisis; and when at the same moment Longstreet was threatened by Humphreys and Wright (II. V.) the situation had arisen in which General Lee considered would justify surrender, an event which had been anticipated on both sides as the result of the fighting around Farmville on the 6th and 7th of April.

But Longstreet, coming over early that morning, offered to move on the 9th of April. Three of May to the 9th of April were all in favor of the Federals, but, nevertheless, the historian counts their losses during this period as nearly 10,000 in the five corps and cavalry which constituted General Grant's field army. On the morning of April 9th, Fitzhugh Lee's and Gordon's corps exchanged formal documents by which 2824 officers and 25494 enlisted men were paroled, all that remained in the field except 32,500 Confederates. The fighting rations took on the 29th of February as the arm of Northern Virginia at Richmond was almost reduced to privation in 1865.

PETERSFIELD, a market town in the Petersfield parliamentary division of Hampshire, England, 55 m. S.W. from London by the London & South Western railway. Pop. of urban district (1901), 3265. The church of St Peter retains some ornate Norman work. The picturesque market-place contains an equestrian statue of William III.

Ecclesiastically a chapelry of Burton, Petersfield (Petersfeld) owes its origin as a borough to the charter granted by William, earl of Gloucester, in the reign of Henry II. and confirmed later by his widow, Hawise. Petersfield is not mentioned in Domesday, but it was probably then included in the manor of Mapledurham. It was a mesne borough possessing by its first charter the liberties and customs of Winchester, together with a merchant guild. The first grant was made by John de Eston in 1415 Henry V. In addition freed the burgesses from all tolls. No charter of incorporation has been found. Gradually privileges and rights other than those of a mesne borough were usurped by the mayor and burgesses, but were recovered by a suit brought against them by Thomas Hanbury, owner of the borough, in 1611. A mayor continued to be elected until 1885. Petersfield was represented in parliament in 1307. No return was then made until 1525-1553, from which date two members were regularly returned. In 1532 the number was reduced to one, and in 1885 the representation was merged in that of the county. Three-day fairs at the Feasts of St Peter and St Andrew were granted in 1255. In 1892 the summer fair then held on the 9th of July was abolished. The autumn fair now held on the 6th of October is for both business and pleasure. The market, which dates from before 1373, formerly held on Saturday, is now held on alternate Wednesdays. In the 16th century Petersfield had important cloth and leather manufactures.

PETER'S PENCE, Rome Scot, or Rom-Fegi, a tax of a penny on every hearth, formerly paid annually to the popes; now represented by a voluntary contribution made by the devout in Roman Catholic churches. Its date of origin is doubtful. The first written evidence of it is contained in a letter of Canute (1037) sent from Rome to the English clergy. At this time it appears to have been levied on all families possessed of land worth thirty pence yearly rental, out of which they paid one penny. Matthew Paris says the tax was instituted by Offa, king of Mercia (757-796) for the upkeep of the English school and hostel at Rome. Layamon, however, declares that An, king of Wessex (688-725), was the originator of the idea. At the Norman Conquest it appears to have fallen into arrears for a time, for William the Conqueror promised the pope in 1076 that it should be regularly paid. By a bull of Pope Adrian IV. the close of general honours from the 20th century, and the tax appears to have been then fixed. The threat of withholding Peter's pence proved more than once a useful weapon against recalcitrant popes in the hands of English kings. Thus in 1366 and for some years after it was refused on the ground of the pope's obstinacy in withholding his consent to the statute of praemunire. During the 10th century the custom of Peter's pence was introduced into Poland, Prussia and Scandinavia, and in the 11th century Gregory VII. attempted to exact it from France and
Spain. The tax was fairly regularly paid by the English until 1534, when it was abolished by Henry VIII.

PETERWARDEIN (Hung. Petervarad, Serv. Petrovaradin), a royal free town and fortress of Hungary in the county of Syrmia, Croatia-Slavonia; situated on a promontory formed by a loop of the Danube, 62 m. N.W. of Belgrade by rail. Pop. (1900), 5091. It is connected with Neusatz on the opposite bank by a bridge of boats, a railway bridge and a steam ferry. The fortifications consist of the upper fortress, on a lofty serpentine rock rising abruptly from the plain on three sides, and of the lower fortress at the northern base of the rock. The two fortresses can accommodate a garrison of 10,000 men. In the lower fortress is the town, with a military hospital, and an arsenal containing trophies captured from the Turks. Peterwardein, the “Gibraltar of Hungary,” is believed to represent the Roman Acclinium, and received its present name from Peter the Hermit, who here in 1056 marshalled the levies of the first crusade. It was captured by the Turks in 1536 and retained by them for 166 years. In 1716 it witnessed a signal defeat inflicted on the Turks by Prince Eugène. During the revolutionary struggles of 1848-49 the fortress was held by the insurgents for a short time.

PETHERICK, JOHN (1813-1882), Welsh traveller in East Central Africa, was born in Glamorganshire, and adopted the profession of mining engineer. In 1845 he entered the service of Mehemet Ali, and was employed in examining Upper Egypt, Nubia, the Red Sea coast and Kordofan in an unsuccessful search for coal. In 1848 Petherick left the Egyptian service and established himself at El Obeid, the capital of Kordofan, as a trader, dealing largely in gum arabic. He was at the same time made British consular agent for the Sudan. In 1853 he removed to Khartum and became an ivory trader. He travelled extensively in the Bahr-el-Ghazal region, then almost unknown, exploring the Jur, Yalo and other affluents of the Ghazal. In 1858 he penetrated to the Niam-Niam country. His additions to the knowledge of natural history were considerable, among his discoveries being the Cobus maria (Mrs Gray’s waterbuck) and the Balaeniceps rex (white-headed stork). Petherick returned to England in 1859 where he made the acquaintance of J. H. Speke, then arranging for his expedition to discover the source of the Nile. While in England Petherick married, and published an account of his travels. He returned to the Sudan in 1861, accompanied by his wife and with the rank of consul. He was entrusted with a mission by the Royal Geographical Society to communicate to Gondokoro relations of Captains Speke and Grant. Petherick got back to Gondokoro in 1863, but Speke and Grant had not arrived. Having arranged for a native force to proceed south to get in touch with the absentees, a task successfully accomplished, Mr and Mrs Petherick undertook another journey in the Bahr-el-Ghazal, making important collections of plants and fishes. They regained Gondokoro (where one of their boats with stores was already stationed) in February 1863, four days after the arrival of Speke and Grant, who had meantime accepted the hospitality of Mr (afterwards Sir) Samuel Baker. The charge that Petherick failed to meet his engagement to those travellers is unsubstantiated. A further charge that Petherick had countenanced and even taken part in slave raids was substantiated only to be dis-avowed in Petherick (in fact had endeavoured to stop the traffic), but it led Earl Russell, then secretary for foreign affairs, to abolish the British consulate at Khartum (1864). In 1865 the Pethericks returned to England, and in 1869 published Travels in Central Africa and Explorations of the Western Nile Tributaries, in which book are set out the details of the Speke controversy. Petherick died in London, on the 19th of July 1882.

PÉTILON DE VILLENEUVE, JÉRÔME (1570-1594), French writer and politician, was the son of a procureur at Chartres. He became an avocat in 1778, and at once began to try to make a name in literature. His first printed work was an essay, Sur les manières de prévenir l’infanticide, which failed to gain the prize for which it was composed, but pleased Brissot so much that he printed it in vol. vii. of his Bibliothèque philosophique des législateurs. Pétion’s next works, Les Lois civiles, and Essais sur le mariage, in which he advocated the marriage of priests, confirmed his position as a bold reformer, and when the elections to the States-General took place in 1780 he was elected a deputy to the Tiers État for Chartres. Both in the assembly of the Tiers État and in the Constituent Assembly Pétion showed himself a radical leader. He supported Mirabeau on the 23rd of June, attacked the queen on the 5th of October, and was elected president on the 4th of December 1790. On the 15th of June 1791 he was elected president of the criminal tribunal of Paris. On the 21st of July 1793 he was chosen as one of three commissioners appointed to bring back the king from Varennes, and he has left a fatuous account of the journey. After the last meeting of the assembly on the 30th of September 1791 Robespierre and Pétion were made the popular heroes and were crowned by the populace with civic crowns. Pétion received a still further proof of the affection of the Parisians for himself on the 16th of November 1791, when he was elected second mayor of Paris in succession to Bailly. In his mayorality he exhibited clearly his republican tendency and his hatred of the old monarchy, especially on the 20th of June 1792, when he allowed the mob to destroy and burn the royal palace of the Tuileries. For neglecting to protect the Tuileries he was suspended from his functions by the Directory of the department of the Seine, but the leaders of the Legislative Assembly felt that Pétion’s cause was theirs, and rescinded the suspension on the 13th of July. On the 3rd of August, at the head of the municipality of Paris, Pétion demanded the dethronement of the king. He was elected to the Convention for Eure-et-Loir and became its first president. L. P. Manuel had the folly to propose that the president of the Assembly should have the same authority as the president of the United States; his proposition was at once rejected, but Pétion got the nickname of “Roi Pétion,” which contributed to his fall. His jealousy of Robespierre allied him to the Girondin party, with which he voted for the king’s death and for the appeal to the people. He was elected in March 1793 to the first Committee of Public Safety; and he attacked Robespierre, who had accused him of having known and having kept secret Dumas’s project of treason. His popularity however had waned, and his name was among those of the twenty-two Girondin deputies proscribed on the 2nd of June. Pétion was one of those who escaped to Caen and raised the standard of provincial insurrection against the Convention; and, when the Norman rising failed, he fled with M. E. Guadet, F. A. Buzot, C. J. M. Barbaroux, J. B. Salle and Louvet de Convrail to the Girondine, where they were received with open arms by the mayor of Saint Émilion. At last, a month before Robespierre’s fall in June 1794, the escaped deputies felt themselves no longer safe, and deserted their asylum; Louvet found his way to Paris, Salle and Guadet to Bordeaux, where they were soon taken; Barbaroux committed suicide; and the bodies of Pétion and Buzot, who also killed themselves, were found in a field, half-eaten by wolves.

See Mémoires inédits de Pétion et mémoires de Buzot et de Barbau- roux, accompagnés de notes inédites de Buzot et de nombreux docu- ments inédits sur Buzot, Buzot, Brissot, &c., précédé d’une introduction par C. A. Dauban (Paris, 1866); Œuvres de Pétion (3 vols., 1792); F. A. Aulard, Les Orateurs de la Constituante (Paris, 1882).

PÉTIS DE LA CROIX, FRANÇOIS (1653-1713), French Orientalist, was born in Paris in 1653. He was son of the Arabic interpreter of the French court, and inherited this office at his father’s death in 1695, afterwards transmitting it to his own son, Alexandre Louis Marie, who also distinguished himself in Oriental studies. At an early age he was sent by Colbert to the East; during the ten years he spent in Syria, Persia and Turkey he mastered Arabic, Persian and Turkish, and also collected rich materials for future writings. He served a short time as secretary to the French ambassador in Morocco, and accompanied as interpreter the French forces sent against Algiers in 1699. In 1710 he was chosen as one of the two members of a commission sent to Algiers to agree to the satisfactory settlement of the war, which was drawn up by himself in Turkish and ratified in 1684. He conducted the negotiations with Tunis and Tripoli
in 1685, and those with Morocco in 1689; and the zeal, tact, and linguistic knowledge he manifested in these and other transactions with Eastern courts were at last rewarded in 1692 by his appointment to the Arabic chair in the Collège Royal de France, which he filled until his death in 1713. He published *Contes turcs* (Paris, 1707), and *Les Mille et un jours* (5 vols., Paris, 1710-1712); an Armenian Dictionary and an *Account of Ethiopia*. But the lasting monument of his literary fame is his excellent French version of Shafar-uddin ‘Ali Yazdi’s *Zafarnāma* or *History of Timūr* (completed 826 A.H.; A.D. 1425), which was given to the world nine years after his death (4 vols., Paris, 1722; Eng. trans., London, 1817). This work was one of the rarest specimens of a fairly critical history Persia can boast of, was compiled under the auspices of Mirzā Ibrāhīm Sultān, the son of Shāh Rukh and grandson of the great Timur. The only English translation of *Zafarnāma* is that of De la Croyère, in his otherwise very valuable work, which he erroneously ascribed the important share which Ibrāhīm Sultān had in the *Zafarnāma* to Timūr himself.

**PETIT, SIR DINSHAW MANECKJI, BART.** (1823-1901), Parsee philanthropist, was born on the 30th of June 1823. As a young man he emigrated to America, where he amassed a large fortune, which he devoted to the period of speculation in Bombay at the time of the American Civil War. In 1866 he became a member of the governor-general’s legislative council. He devoted his wealth to philanthropic objects, among the public and private charities which he endowed being the Towers of Silence and fire temples of the Parsees, a hospital for animals, a college for women, and the Petit hospital. He was knighted in 1887, created a baronet in 1890, and died in February 1901.

**PETIT DE JUVELLE, LOUIS** (1841-1900), French scholar, was born in Paris on the 18th of July 1841. Educated at the École des Chartes and the École française de Rome, where he received his doctorate in literature in 1868. After holding various posts as a teacher he became professor of French medieval literature and of the history of the French language in the university of Paris in 1886. He died on the 28th of August 1900. His most important works are: *Histoire du théâtre en France*, including *Les Mystères* (2 vols., 1880); *Les Comédies en France au moyen âge* (1883); *La Comédie et les mœurs en France au moyen âge* (1886); *Répertoire du théâtre comique en France au moyen âge* (1886); and *Le Théâtre en France, histoire de la littérature dramatique depuis le moyen âge jusqu’au XVIIIe siècle*, in two volumes. Petit de Juvelle was also the general editor of the *Histoire de la langue et de la littérature française* (8 vols., 1896-1900), to which he himself contributed some valuable chapters.

**PETITION** (Lat. for “seeking” or “praying”), a term meaning generally a prayerful request, and in its more important constitutional aspect an application for redress by a person aggrieved to an authority capable of receiving him. It may be made in the United Kingdom to the Crown or to his officers, or to either house of parliament, in certain cases to courts of justice.

**Petitions to the Crown.**—The right of petitioning the Crown was recognized indirectly as early as Magna Carta in the famous clause, *nullum vendemus, nullum negabimus aut differemus, rectum vel justitiam* (25 Edw. I. c. 29), and directly at various periods later, e.g. in the articles of the Commons assented to by Henry IV., by which the king was to assign two days in the week for petitions (Rot. Parl. 8 Hen. IV., p. 585). The case of the seven bishops in 1668 confirmed the right, and finally the Bill of Rights in 1688 established the right to the subjects to petition the king, and all committees and proceedings for suppressing or obstructing are illegal.” Petitions to the Crown appear to have been at first for the redress of private and local grievances, or for remedies which the courts of law could not grant (May, Parl. Pr., 11th ed., 522). As equity grew into a system, petitions of this kind seeking legislative remedies tended to become superseded by bills in chancery. Statutes were originally drawn up by the judges at the close of the session of parliament from the petitions of the Commons and the answers of the Crown. Under this system of drafting it was found that the tenor of the petition and answer were not always stated correctly. To obviate this inconvenience drafts were introduced in the reign of Henry VI. to be drawn up in the form of bills which the Crown could accept or reject, but could not alter (see Anson, *Law and Custom of the Constitution*, 3rd ed., vol. i. p. 241). In the same reign the words “by authority of parliament” were added to the words of enactment, and from the time of Henry VII. public legislation has been by bill and not by petition. A relic of the old form of statute founded upon petition still remains however in the preamble of Appropriation Acts and other statutes creating a charge upon the public revenue. It runs thus: “We, your majesty’s most dutiful and loyal subjects, the Commons of the United Kingdom do... do most humbly beseech your majesty that it may be enacted; and be it enacted,” &c., from this point following the enacting words common to all statutes. The Crown may refer petitions presented to it to be adjudicated upon by the relevant and appropriate courts, and may be bound, in the absence of such a declaration, to receive and answer them.

**Petitions to Parliament.**—Petitions to either house of the legislature seem to have been later in origin than petitions to the Crown. They are not referred to in the Bill of Rights, but the right of petition is a convention of the constitution. Petitions to the Lords or the whole parliament can be traced back to Henry III. No petition to the Commons has been found earlier than that of Richard II.; but from the time of Henry IV., petitions to the Commons have been freely made. The political importance of petitioning dates from about the reign of Charles I. The development of the practice of petitioning had proceeded so far in the reign of Charles II. as to lead to the passing in 1662 of an act (13 Car. II. c. 5) against “tumultuous petitioning,” which is still on the statute book. It provides that no petition or address shall be presented to the king or either house of parliament by more than ten persons; nor shall any one procure above twenty persons to consent or set their hands to any petition for alteration of matters established by law in church or state, unless with the personal concurrence of the speaker of the house of commons. 

**Petitions to the Crown.**—In 1862 the title was changed to “petitions from the people to the government.” But from the time of Henry IV., petitions to the Commons have been freely made. The political importance of petitioning dates from about the reign of Charles I. The development of the practice of petitioning had proceeded so far in the reign of Charles II. as to lead to the passing in 1662 of an act (13 Car. II. c. 5) against “tumultuous petitioning,” which is still on the statute book. It provides that no petition or address shall be presented to the king or either house of parliament by more than ten persons; nor shall any one procure above twenty persons to consent or set their hands to any petition for alteration of matters established by law in church or state, unless with the personal concurrence of the speaker of the house of commons. 

**Petitions to Courts of Justice.**—Strictly speaking, these are an indirect mode of petitioning the Crown, for in the theory of English law the Crown is the fountain of justice. But it is more convenient to treat them separately, as they now form a part of the practice of the courts. Appeals to the House of Lords and the privy council are prosecuted by petition of appeal. The
original jurisdiction of the privy council to deal with petitions is confined to proceedings under certain statutes, such as the Endowed Schools Acts, the Public Schools Acts, the Universities Acts and the Patents Acts. In most cases the petitions are referred to the judicial committee of the council. Petitions may be addressed to the lord chancellor in a few instances, e.g., for the removal of coroners or county court judges. The House of Lords at one time claimed original jurisdiction in civil and criminal matters. As to civil matters the claim is abandoned, as it is thought to be a limited to impeachment for crime by the Commons on the trial for treason or felony of persons having privilege of peerage.

The most important use of petitions in England is in the High Court of Justice. In the chancery division petitions are presented either as interlocutory proceedings in the course of an action, or as original petitions where there is no litigated dispute—a more speedy form of remedy than an action. The cases in which a petition is admissible and the procedure therein, are in the main regulated by orders 52 and 55 of the Rules of the Court. Evidence in support of petitions is usually by affidavit. Petitions in the course of an action are presented to the court in which the action is brought. Examples of original petitions are those under the Lands Clauses Acts, the Trustee Acts and the Companies Acts. For many proceedings under these acts a simpler and cheaper form of proceeding by summons has been substituted for that by petition. The matters above-mentioned are usually dealt with by the chancery division, but the action division of the courts of chancery are also in use in other courts having equitable jurisdiction, e.g., the chancery courts of the counties palatine of Lancaster and Durham and the county courts as to cases falling within § 67 of the County Courts Act 1888, and which are within the jurisdiction under the Settled Land Acts or the Guardianship of Infants Act 1886 (County Court Rules, O. 35). In a few cases petitions may be brought by way of appeal, e.g., under the Charitable Trusts Act 1862, the Commissioners for the King's Revenue Act 1887, and the Divorce Acts. A petition appears to be to initiate proceedings in bankruptcy. Leave to sue in formae pauperei used to be given on petition but is now usually dealt with summarily. In the probate, &c., division proceedings in matrimonial causes, &c., are begun by petition, but the course of the proceedings closely resembles that of an ordinary action.

Ireland.—In Scotland petitions in the Court of Session are either original or in a pending action. Original petitions are presented to one of the divisions of the inner house, unless they relate to matters mentioned in 20 & 21 Vict. c. 56, s. 4, when they are brought before the junior lord ordinary, or unless, by special statutory provision, they may be brought before any lord ordinary, as in the case of petitions under the "Conjugal Rights (Scotland) Amendment Act 1861," or the Trusts (Scotland) Act 1867. A petition and complaint is a quasi-original proceeding. In matters of summary and extraordinary jurisdiction are brought under the notice of the Court of Session. It lies against magistrates and officers of the law for breach of duty against parties guilty of irregularity, or the like. The rule in Cole v. Cowper, 1837, 65 R. 109, is to the effect that a complaint is necessary to a petition and complaint (see Mackay, Court of Session Practice, ii. 439).

IRELAND.—The law of Ireland as to petitions is in substance the same as that of England. It is difficult to compare the cases in which petitions may be made to courts of justice.

UNITED STATES.—In the United States before the Civil War questions arose as to the right of petitioning Congress, particularly with reference to petitions for the restriction of slavery within the states. It was contended to be a matter of state and not of federal concern (see Cooley, Constitutional Limitations, 6th ed., 1890, 426). The right of petitioning the United States government is now secured by the preamble to the constitution. The right of petition is found in 1789-1791, which provides that "Congress shall make no law...abridging...the right of the people peaceably to assemble and petition the government for a redress of grievances." In the view of the Supreme Court the right represented the existence of the right of the people to assemble for lawful purposes and protects it against encroachment by Congress. The right was not created by the amendment; neither was its continuance guaranteed except as against an infringement of the right of assembly, the protection of which right is guaranteed by the United States. The very idea of a government republican in form implies a right on the part of its citizens to meet peaceably for consultation in respect to public affairs and to petition for a redress of grievances (U.S. v. Cruikshank, 1875, 92 U.S. 542, 552).

A Bill of Rights is incorporated in the constitutions of many states of the Union, and is made part of the supreme law of the states (see Hough, American Constitutions, ii. 571). Petitions can be presented to the federal or state courts of justice under much the same circumstances as in England. It is a general rule in the United States that an application for redress contained in a petition is as effective as a formal complaint, provided it is true. Whether an action is made for damages, or to enforce a claim, or for an injunction, or to recover specific property, or to enjoin an act, or to obtain compensation for an act, it is a question of fact in each case. The petition should set forth in detail the facts on which the claim or defense is based. The facts should be stated in a clear and concise manner, and should be accompanied by such arguments as are necessary to sustain the claim or defense. In most cases it is advisable to have the petition drawn by a lawyer. The rules of evidence and the rules of practice of the court to which the petition is presented should be consulted when preparing the petition. The court will consider the petition on its merits, and will grant judgment accordingly.

The term Petition of Right, in English law, is used in two senses. (1) It denotes the statute of 1625 (3 Cant. I. 1.), a parliamentary declaration of the liberties of the people. (2) It also and more usually is employed to describe a mode of prosecuting a claim by a subject against the Crown, said to owe its origin to Edward I. Petition of right in this sense lies (a) to obtain restitution of real or personal property of the subject which has found its way into the hands of the Crown, or compensation if restitution cannot be made; (b) to recover damages for breach of a contract made on behalf of the Crown, whether the breach is due to the acts or the omissions of servants of the Crown. Where the Crown is in possession of property of the suppliant, and the title of the Crown appears by record, as by inquest of office, the remedy is somewhat different and is called monstrans de droit. Petition of right does not lie in respect of engagements in the naval, military or civil service of the Crown, which are as a general rule made "during pleasure," nor for breaches of contract, e.g., failure to perform treaty obligations, nor for trespass or negligence in the acts of the Crown servants. Where such acts are wrongful the remedy is by action against the official as an individual and not in his official capacity (Raleigh v. Goschen, 1838, L.R. 1 ch. 73).

The procedure on a petition of right is either at common law or by statute. At common law the petition went through its earliest stages in the chancery. It suggests such a right as controverts the right of the Crown to some part of property in the hands of the Crown, e.g., the petition Seti droit fait a partie. Thereupon a commission is issued for the return of the information. After the return to the commission, the attorney-general pleads or demurs, and the merits are then determined as in actions between subject and subject. If the right be determined against the Crown, judgment of amovans manus is given in favour of the suppliant. The Petition of Right Act 1860 (23 & 24 Vict. c. 34) extended to Ireland in 1873, 36 & 37 Vict. c. 32. In the United States the doctrine is assimilated, but where the subject-matter of the petition arises out of the exercise of belligerent rights of the United States against the Crown, or was cognizable in a prize court if the matter were in dispute between private persons, the suppliant may recover on the petition, subject to the qualifications in the statute. The lord chancellor may direct the prosecution in that division of petitions of right under the act of 1860 even when they are not so intituled (27 & 28 Vict. c. 25, s. 52).

The law as to petition of right applies to Ireland but not to Scotland, and a right to present such a petition appears to exist in colonies whose law is based upon the common law of England. But in many colonies legislation has been passed with respect to petitions of right which makes it unnecessary to resort to a petition of right.

PETITIO PRINCIPII, OR BEGGING THE QUESTION (Gr. τὸ ἐκ ἀρχῆς λαμβάνειν, τὸ ἐκ ἀρχῆς αἰτεῖθαι, in logic, the fourth of Aristotle's fallacies ἐξω τῆς λέξεως or extra dictum. Strictly this fallacy belongs to the language of disputation, when the questioner seeks (petit) to get his adversary to admit the very matter in question. Hence the word principium gives a wrong impression, for the fallacy consists not in seeking for the
admission of a principle which will confute the particular proposition—a perfectly legitimate form of refutation—but in luting the adversary into confessing the contradictory. In the ordinary use, however, "begging the question" consists in assuming in the premises the conclusion which it is desired to prove.

PETITOT, JEAN (1668–1691), French-Swiss enamel painter, was born at Geneva, a member of a Burgundian family which had fled from France on account of religious difficulties. His father, Faule, was a wood carver; his mother's name was Étiennette Royanne. Jean was the fourth son, and was apprenticed to a jeweller goldsmith named Pierre Bordier, with whom he struck up a close friendship. The two friends, dissatisfied with the progress they made in Geneva, went into France, and after working for a while with Toutin came to England with letters of introduction to Turquet de Mayerne, physician to Charles I., who presented them to the king, for whom they made a St George for the badge of the order and carried out many commissions for portraits; amongst others preparing two large ones representing Rachel de Ruvigny, countess of Southampton, now at Chatsworth, and Mary Villiers, duchess of Richmond and Lennox, dated 1643, at one time in the possession of the Crown and now in the Pierpont Morgan collection. On the execution of the king, Petitot left England for Paris with the royal household, Bordier remaining in England and carrying out certain important commissions for Cromwell and the parliament. On reaching Paris, Petitot entered into partnership with a goldsmith, Jacques Bordier, a cousin of Pierre, and it seems probable from recent research in contemporary documents that the enamel portraits attributed to Petitot were really the work of the two partners collaborating, the actual drawing being the work of Petitot, while for the enamel process Bordier was mainly responsible. The two painters were given apartments in the Louvre, received numerous commissions from Louis XIV., and painted portraits of almost every person of importance in his brilliant court. The friendship between the two lasted for thirty-five years, and was only put an end to by Bordier's death. The enamellers rendered special political services in France for the republic of Geneva, and were practically regarded as the official representatives of the republic, receiving warm thanks from the Syndics for their diplomatic work. On the revocation of the Edict of Nantes, 1685, pressure was brought to bear upon Petitot that he should change his religion. The king protected him as long as possible, and when he was arrested, with his niece, Anne Bordier, sent Bossuet, bishop of Meaux, to convince the old man of the error of his ways. Eventually, in poor health and great despair, Petitot placed his signature to an act of abjuration, and Louis XIV., unwilling to acknowledge the true reason for the imprisonment of Petitot and for his liberation, informed one of his sons, who was in Scotland, of this fact, with the reflection that he was willing to fall in for once with "the whim of an old man who desired to be buried with his ancestors." In 1687 therefore Petitot left Paris to return to Geneva, and, after a long and tedious inquiry, was absolved by the consistory of the church of Geneva from the crime of which they considered he had been guilty, and received back to the Huguenot communion in the church of St Gervais. In Geneva he received a very important commission from John Sobieski, king of Poland, who required portraits of himself and his queen. This was followed by numberless other commissions which the painter carried out. He died of paralysis on the 3rd of April 1691, while in the very act of painting on the enamel a portrait of his faithful wife.

Petitot married in 1651 Marguerite Cuper, and Jacques Bordier married in the same year her younger sister Anne Madeleine. He had seventeen children, and for their benefit wrote out a little octavo volume containing some genealogical information, two delightful portraits, one of himself and one of his wife, and many pages occupied with prayers, meditations and religious advice. He also prepared a second manuscript volume of prayers and meditations for the use of his family, and from these two books and the records of the Huguenot societies of France and England information has been obtained regarding the painter and his family.

Of the works of Petitot the most important collection is in the Jones Bequest at the Victoria and Albert Museum. There are many in the Louvre, sixteen at Chantilly, seventeen at Windsor, but the best are in the collection of Lord Beauchamp, the heir of the duke of Richmond, and in the collection in the early 1700s of Mr Stroehlin of Geneva. In Mr Pierpont Morgan's collection there are many exceedingly fine examples, and amongst these the portraits of and of his son, are the finest in existence. A second portrait of the artist belongs to the queen of Holland, and another is in the collection of the late Mr Stroehlin of Geneva. In Mr Pierpont Morgan's collection there are many exceedingly fine examples, but especially three drawings in pen, the only three which appear to have survived, and the large signed miniature of the duchess of Richmond already mentioned, the largest work Petitot ever executed save the one at Chatsworth.

PETITOT, JEAN LOUIS (1652–1730), French enamel painter, was the eldest son of Jean Petitot (q.v.), and was instructed in enamelling by his father. Some of his works so closely resemble those of the elder Petitot that it is difficult to distinguish between them, and he was really the only serious rival his father ever had. He settled for a while in London, where he remained till 1682, and painted many enamel portraits of Charles II. In 1682 he removed to Paris, but in 1695 was back again in London, where he married Rachel de Ruvigny, countess of Southampton. His portrait by Mignard is in the museum at Geneva, and another in enamel by himself in the collection of the earl of Darnley, who also owns two of his wife, Madeleine Bordier, whom he married in 1683. Another portrait believed to represent him is in the collection of Mr Pierpont Morgan.

PETITS-CHEVAUX (Fr. for "little horses"), a gambling game played with a mechanical device consisting of a board perforated with a number of concentric circular slits, in which revolve, each independently on its own axis, figures of jockeys on horseback, the horses being slotted into the slits and staked their money according to their choice on a board marked in divisions for this purpose, the horses are started revolving rapidly together by means of mechanism attached to the board, and the horse which stops nearest a marked goal wins, every player who has staked on that horse receiving so many times his stake. Figures of railway trains and other objects sometimes take the place of horses. In recent years there has been a tendency to supplant the petits chevaux at French resorts by the boule or ball game, on the same principle of gambling, in this a ball is rolled on a basin-shaped table so that it may eventually settle in one of a number of shallow cups, each marked with a figure.

PETITOT, SAMUEL MOORE, 3rd Marquess (1800–1889), English commodore, was born at Woking, Surrey, on the 4th of August 1800, and was at an early age apprenticed to his uncle, a London builder, who on his death in 1830 bequeathed the business to Petot and another nephew, Thomas Grissel. The partnership between Petot and Grissel lasted till 1846, amongst the many London buildings erected by the firm being the Reform Club, the Lyceum and St James's theatres, and the Nelson column. Petot afterwards entered into partnership with Edward Ladd Betts (1815–1872), and between 1846 and 1872 Messrs Petot & Betts carried out many large railway contracts at home and abroad, notably the more important portions of the South-Eastern and of the London Chatham & Dover lines, and in conjunction with Thomas Brassey, the Grand Trunk railway of Canada, and the London Tilbury & Southend railway. In 1854–1855 Petot and Brassey constructed a railway in the Crimea between Balaklava and the British entrenchments before Sebastopol, charging the British government, only the actual out-of-pocket expenses, and for his services in this matter Petot was in 1855 made a baronet. Petot entered parliament as a Liberal in 1847, and, with a few years' interval, continued there till 1868, when, his firm having been compelled to suspend payment in the financial crisis of 1866, he was compelled to resign his seat, though both Mr Disraeli and Mr Gladstone publicly eulogised his personal character. He died on the 13th of November 1889.
PETŐFI, ALEXANDER (1823-1849), Hungarian lyric poet, was born at Kis-Körösö, Pest county, on New Year's Day, 1823. The family received its diploma of nobility from the emperor Leopold in 1688, but the ultra-patriotic Alexander early changed the old family name, Petrovs, which pointed to a Croat origin, into the purely Magyar form of Petőfi. The lad's early days were spent at Fehérgyház and Szabadzállás, the most Hungarian parts of Hungary, where he got most of his early education including a good grounding in Latin. German he learnt subsequently at Pest, and French he taught himself. He began writing verses in his twelfth year, while a student at the Aszód gymnasium, where he also displayed a strong predilection for the stage, to the disgust of his rigorous father, who formally disinherited his son, early in 1839, for some trilling peccadillo, and whose tyrannical temper became downright furious when a series of misfortunes ruined him utterly in 1840. For the next three years Petőfi led the wretched life of a strolling player, except for a brief interval when, to escape starvation, he enlisted as a common soldier in an infantry regiment. During the greater part of 1842 we find him a student at the Calvinist College at Pápa, where he made the acquaintance of young Jókai, and wrote the poem "Borozd," which the great critic Bajácsy placed at once in the leading literary review, the Athenaenaeum (May 22, 1842).

In November of the same year the restless poet quitted Pápa to join another travelling troupe, playing on one occasion the Fool in King Lear, and after wandering all over Hungary and suffering incredible hardships, finally settled down at Pesth (1844), where for a time he supported himself by all sorts of literary hack-work. Nevertheless, in the midst of his worst privations he had read voraciously, and was at this time profoundly influenced by the dominant Romanticism of the day; while, through Tieck, he learnt to know and value the works of Shakespeare. His first volume of original poems was published in 1844 by the Society Nemzeti Kör, through the influence of the poet Vörösmarty, when every publisher had refused his MS., and the seventy-five florins which he got for it had become a matter of life or death to him. He now became a regular contributor to the leading papers of Pest, and was reconciled to his parents, whom he practically supported for the rest of their lives out of his literary earnings. His position, if not exactly brilliant, was now at least secure. The little volume published by the Nemzeti Kör was followed by the parody, A Házvágó Kolgáspás (1844); the romantic epic János Vitéz (1844); Cíprisombor Etelké Síjról, a collection of passionate elegies over his lost love, Etelké Csápi (1845); Ut Jazzik, an imitation of Heine's Reisbilder (1845); Szerelmek gyöngye (1845); Petőfi és kánya (1846); and many other volumes. The first edition of his collected poems appeared in 1847. Petőfi was not yet twenty-five, and, despite the protests of the classicists, who regarded him with cold dislike, the best heads in Hungary, poets like Vörösmarty and critics like Szemere, already paid him the homage due to the prince of Magyar lyrical poets. The great public was enthusiastic on the same side, and posterity, too, has placed him among the immortals. Petőfi is as simple and genuine a poet of nature as Wordsworth or Christian Winther, and his erotics, inspired throughout by a noble idealism, have all Byron's force and fervour, though it is perhaps in his martial songs that Petőfi's essentially passionate and defiant genius is best triumphantly revealed.

On the 8th of September 1847 Petőfi married Julia Szendrey, who bore him a son. When the revolutionary war broke out, he espoused the tenets of the extreme democratic faction with a heat and recklessness which estranged many of his friends. He took an active part in the Transylvanian campaigns of the heroic Bem; rose by sheer valour to the rank of major; was slain at the battle of Segesvár (July 31, 1849), and his body, which was never recovered, is supposed to have been buried in the common grave of the fallen heroes in the churchyard of Fehéregyház. The first complete edition of Petőfi's poems appeared in 1874. The best critical edition is that of Harsány, 1894. There are numerous indifferent German translations.

See Ferenczi, Petőfi Életrajza; Fischer, Petőfi's Leben und Werke. (R. N. B.)

PETOSKEY, a city and the county-seat of Emmet county, Michigan, U. S. A., on Little Traverse Bay, an arm of Lake Michigan, at the mouth of Bear Creek, in the north-west part of the lower peninsula. Pop. (1850), 2872; (1900), 5285, of whom 856 were foreign-born; (1904), 5180; (1910), 4778. It is served by the Pere Marquette and the Grand Rapids & Indiana railways and by steamboat lines to Chicago, Detroit, Buffalo and other lake ports. Bear Creek furnishes considerable water-power, and among the manufactures are lumber, paper, leather and foundry and machine-shop products. Petoskey was settled about 1874, was incorporated as a village in 1879, and was chartered as a city in 1895, and in 1902 replaced Harbor Springs as county-seat. It was named after an Ojibwa Indian chief.

PETRA (ἡ Πέτρα = the rock), a ruined site, 30°10' N. and 35°10' E., lying in a basin among the mountains which form the eastern flank of Wadi el-'Arabā, the great valley running from the Dead Sea to the Gulf of 'Aqāba. The descriptions of Strabo (xvi. p. 779), Pliny (N. H. vi. 32) and other writers leave no doubt as to the identity of this site with the famous capital of the Nabataeans (q.v.) and the centre of their caravan trade. Walled in by towering rocks and watered by a perennial stream, Petra was a great commercial centre with the main commercial routes which passed through it to Gaza in the west, to Bostra and Damascus in the north, to Elath and Leucis Comē on the Red Sea, and across the desert to the Persian Gulf.

From the 'Arabā travellers approach by a track which leads round Jebel Hārūn (Mt Hor) and enters the plain of Petra from the south; it is just possible to find a way in from the high plateau on the north; but the most impressive entrance is from the east, down a dark and narrow gorge, in places only 10 or 12 ft. wide, called the Sik, i.e. the shaft, a split in the huge sandstone rocks which serves as the waterway of the Wadi Mūṣā. Near the end of the defile stands the most elaborate of the ruins, el-Harame or "the Treasury of Pharaoh," not built but hewn out of the cliff; a little farther on, at the foot of the mountain called el-Nejr, comes the theatre, so placed as to bring the greatest number of tombs within view; and at the point where the valley opens out into the plain the site of the city is revealed with striking effect. Almost enclosing it on three sides are rose-coloured mountain walls, divided into groups by deep fissures, and lined with rock-cut tombs in the form of towers. The stream of Wadi Mūṣā crosses the plain and disappears among the mountains opposite; on either bank, where the ground is fairly level, the city was built, covering a space of about 13 sq. m. Among the ruins on the south bank stand the fragments of a temple called Kasr Fir'ūn of late Roman date; just beyond this rises a rocky height which is usually regarded as the acropolis.

A position of such natural strength must have been occupied early, but we have no means of telling exactly when the history of Petra began; the evidence seems to show that the city was of relatively late foundation, though a sanctuary (see below) may have existed there from very ancient times. This part of the country was assigned by tradition to the Horites, i.e. probably "cave-dwellers," the predecessors of the Edomites (Gen. xiv. 6, xxxvi. 20-22; Deut. ii. 12); the habits of the original natives may have influenced the Nabataean custom of burying the dead in rock-cut tombs; but that the Edomites created this city is certain. But that Petra itself is mentioned in the Old Testament cannot be affirmed with certainty; for though Petra is usually identified with Sella which also means "a rock," the reference in Judges i. 36; Isa. xvi. 1, xlii. 11; Obad. 3, is far from clear. 2 Kings xiv. 7 seems to be more explicit; in the parallel passage, however, Sela is understood to mean simply the "rock" (2 Chr. xvu. 12, see LXX). Hence many authorities doubt whether any town named Sela is mentioned in the Old Testament. What, then, did the Semitic
inhabitants call their city? Eusebius and Jerome (Onom. saccr. 286, 71. 145. 9; 283, 55. 287, 34), apparently on the authority of Josephus (Ant. iv. 17. 4, 7), assert that Rekem was the native name. But in the Aramaic versions Rekem is the name of Kadesh; Josephus may have confused the two places. Sometimes the Aramaic versions give the form Rekem-Geya, which recalls the name of the village El-jii, south-east of Petra; the capital, however, would hardly be defined by the name of a neighbouring village. The Semitic name of the city, if it was not Sela', must remain uncertain.\(^1\) The passage in Diodorus Siculus (xix. 94-97) which describes the expeditions which Antigonus sent against the Nabataeans in 312 B.C. is generally understood to throw some light upon the history of Petra, though it must be admitted that the country referred to as a natural fortress and place of refuge cannot be a proper name, and the description at any rate implies that the town was not yet in existence. Brünnow thinks that "the rock" in question was the sacred mountain en-Nejr (above); but Buhl suggests a conspicuous height about 16 m. north of Petra, Shobak, the Mont-royal of the Crusaders.\(^2\) More satisfactory evidence of the date at which the earliest Nabataean settlement began is to be obtained from the inscriptions within the tombs. Two types may be distinguished broadly, the Nabataean and the Graeco-Roman. The Nabataean type starts from the simple pylon-tomb, with a single room or chamber, and is characterized by the presence of a simple lintel or parapet in imitation of the front of a dwelling-house; then, after passing through various stages, the full Nabataean type is reached, retaining all its original features and at the same time exhibiting characteristics which are partly Egyptian and partly Greek. Of this type there exist close parallels in the tomb-towers at el-Hejr in north Arabia, which bear long Nabataean inscriptions,\(^3\) and so supply a date for the corresponding monuments at Petra. Then comes a series of tomb-fronts which terminate in a semicircular arch, a feature derived from north Syria, and finally the elaborate façades, from which all trace of native style has vanished, copied from the Imperial type with a certain amount of adaptation. The precise date at which this development cannot be fixed, for strangely enough few inscriptions of any length have been found at Petra,\(^4\) perhaps because they have perished with the stucco or cement which was used upon many of the buildings. We have, then, as evidence for the earliest period, the simple pylon-tombs, which belong to the Hellenistic age; how far back in this stage the Nabataean settlement goes we do not know, but not farther than the 6th century B.C. A period follows in which the dominant civilization combines Greek, Egyptian and Syrian elements, clearly pointing to the age of the Ptolemies. Towards the close of the 3rd century B.C., when the Ptolemaic and Seleucid kingdoms vied with each other for the Nabataean territory, the construction with a pylon front becomes the rule; under Aretas III. Philhellene, c. 85-60 B.C., the royal coins begin; at this time probably the theatre was excavated, and Petra must have assumed the aspect of a Hellenistic city. In the long and prosperous reign of Aretas IV. Philpatris, 9 B.C.-A.D. 40, the fine tombs of the el-Hejr type may be dated, perhaps also the great High-place. Then the city became more and more Romanized. In A.D. 106, when Cornelius Palma was governor of Syria, "Arabia belonging to Petra,"\(^5\) was absorbed into the Roman Empire, and the native dynasty came to an end. But the city continued to flourish. It was visited in A.D. 131 by Hadrian, and stood about 150 A.D. as an important place for the coasting trade; and it remained a Roman town till the Arab conquest in 639. For a short time the city enjoyed a brief but splendid prosperity, its coinage imitating that of Trajan and Hadrian.
took refuge in the Ghibelline township of Arezzo; and it was here, on the very night when his father, in company with other members of the White party, made an unsuccessful attempt to enter Florence by force, the Francesco first saw the light. He did not remain long in his birthplace. His mother, having obtained permission to return from banishment, settled at Incisa, a little village on the Arno above Florence, in February 1305. Here Petrarch spent seven years of boyhood, acquiring that pure Tuscan idiom which afterwards he used with such consummate mastery in ode and sonnet. Here, too, in 1307, his brother Gherardo was born. In 1312 Petracco set up a house for his family at Pisano; but soon afterwards, finding no hope for the exercise of his profession as jurist, he removed them all in 1313 to Avignon. This was a step of no small importance for the future poet-scholar. Avignon at that period still belonged to Provence, and owned King Robert of Naples as sovereign. But the popes had made it their residence after the insults offered to Boniface VIII. at Anagni in 1303. Avignon was therefore the centre of that varied society which the high pontiffs of Christendom have ever gathered round them. Nowhere else could the youth of genius who was destined to impress a cosmopolitan stamp on medieval culture and to begin the modern era have grown up under conditions more favourable to his task. At Avignon, Petracco had learned his mother-tongue. At Carpentras, under the direction of Convenone of Prato, he studied the humanities between the years 1315 and 1320. Avignon, at a distance from the party strife and somewhat parochial politics of the Italian commonwealths, impressed his mind with an ideal of civilisation raised far above provincial prejudices.

Petrarch’s real name according to Tuscan usage was Francesco di Petracco. But he altered this patronymic, for the sake of euphony, to Petrarca, proving by this slight change his emancipation from usages which, had he dwelt at Florence, would most probably have been imposed on him. Petracco, who was very anxious that his eldest son should become an eminent jurist, sent him at the age of fifteen to study law at Montpellier. Like Ovid and many other poets, Petrarch felt no inclination for his father’s profession. His intellect, indeed, was not incapable of understanding and admiring the majestic edifice of Roman law; but he shrank with disgust from the illiberal technicalities of practice. There is an authentic story of Petracco’s flinging the young student’s books of poetry and rhetoric upon the fire, but saving Virgil and Cicero half-burned from the flames at his son’s passionate entreaties. Notwithstanding Petrarch’s firm determination to make himself a scholar and a man of letters rather than a lawyer, he so far submitted to his father’s wishes as to enter the degree of 1273 at Padova, which, as we shall see, was headquarters of juristic learning. There he stayed with his brother Gherardo until 1326, when his father died, and he returned to Avignon. Banishment and change of place had already diminished Petracco’s fortune, which was never large; and a fraudulent administration of his estate after his death left the two heirs in almost complete destitution. The most precious remnant of Petrarch’s inheritance was a MS. of Cicero. There remained no course open for him but to take orders. This he did at once on his arrival in Provence; and we have good reason to believe that he advanced in due time to the rank of priest. A great Roman noble and ecclesiastic, Giacomo Colonna, afterwards bishop of Lombez, now befriended him, and Petrarch lived for some years in partial dependence on this patron.

On the 6th of April 1337 happened the most famous event of Petrarch’s history. He saw Laura for the first time in the church of St Clara at Avignon. Who Laura was remains uncertain still. That she was the daughter of Audibert de Noves and the wife of Hugh de Sade rests partly on tradition and partly on documents which the abbé de Sade professed to have copied from originals in the 18th century. Nothing is now extant to prove that, if this lady really existed, she was the Laura of the Canzoniere, while there are reasons for suspecting that the abbé was either the fabricator of a romance flattering to his own family, or the dupe of some previous impostor. We may, however, reject the sceptical hypothesis that Laura was a mere figment of Petrarch’s fancy; and, if we accept her personal reality, the poems of her lover demonstrate that she was a married woman with whom he enjoyed a respectful and not very intimate friendship.

Petrarch’s inner life after this date is mainly occupied with the passion which he celebrated in his Italian poems, and with the friendships which his Latin epistles dimly reveal to us. Besides the bishop of Lombez he was now on terms of intimacy with another member of the great Colonna family, the cardinal Giovanni. A German, Ludwig, whom he called Socrates, and a Roman, Lello, who received from him the classic name of Laelius, were among his best-loved associates. Avignon was the chief seat of his residence up to the year of 1333, when he was restless and undertook his first long journey. On this occasion he visited Paris, Ghent, Liège, Cologne, making the acquaintance of learned men and copying the manuscripts of classical authors. On his return to Avignon he engaged in public affairs, pleaded the cause of the Scaligers in their lawsuit with the Rossi for the lordship of Parma, and addressed two poetical epistles to Pope Benedict XII. upon the restoration of the papal see to Rome. His eloquence on behalf of the tyrants of Verona was successful. It won him the friendship of their ambassador, Azzo di Correggio—a fact which subsequently influenced his life in no small measure. Not very long after these events Petrarch made his first journey to Italy, a long drawn-out tour, during which he saw nothing of the country which he has left us of the impression he received from its ruins.

It was some time in the year 1337 that he established himself at Vaucluse and began that life of solitary study, heightened by communion with nature in her loneliest and wildest moods, which distinguished him in so remarkable a degree from the common herd of medieval scholars. Here he spent his time partly among books, meditating on Roman history, and preparing himself for the Latin epic of Africa. In his hours of recreation he climbed the hills or traced the Sorgues from its fountain under those tall limestone cliffs, while odes and sonnets to Madonna Laura were prepared in his memory to paper. We may also refer many of his most important treatises in prose, as well as a large portion of his Latin correspondence, to the leisure he enjoyed in this retreat. Some woman, unknown to us by name, made him the father of a son, Giovanni, in the year 1337; and she was probably the same who brought him a daughter, Francesca, in 1343. Both children were afterwards legitimized by papal bulls. Meanwhile his fame as a poet in the Latin and the vulgar tongues steadily increased, until, when the first draughts of the Africa began to circulate about the year 1339, it became manifest that no one had a better right to the laurel crown than Petrarch. A desire for glory was one of the most deeply-rooted passions of his heart, and the one to which he most strongly associated the humanistic scholars who succeeded him. It is not, therefore, surprising to find that he exerted his influence in several quarters with the view to obtaining the honours of a public coronation. The result of his intrigues was that on a single day in 1349, the 1st of September, he received two invitations, from the university of Paris and from King Robert of Naples respectively. He chose to accept the latter, journeyed in February 1341 to Naples, was honourably entertained by the king, and, after some formal disputations on matters touching the poet’s art, was sent with magnificent credentials to Rome. There, in the month of April, Petrarch assumed the poet’s crown upon the Capitol from the hand of the Roman senator amid the plaudits of the people and the patricians. The oration which he delivered on this occasion was composed upon these words of Virgil—

"Sed me Parnassi deserta per ardua dulcis
Raptat amor."
the foundations of his own tyranny in that city. He invited Petrar...
PETRARCH

Violante Visconti, a few years later, was wedded to the English duke of Clarence. Petrarch was now commissioned to congratulate King John upon his liberation from captivity to England. This duty performed, he returned to Milan, where in 1361 he received news of the deaths of his son Giovanni and his old friend Socrates. Both had been carried off by plague.

The remaining years of Petrarch's life, important as they were for the furtherance of humanistic studies, may be briefly condensed. On the 15th of May 1362 he settled at Padua, from the neighbourhood of which he never moved again to any great distance. The same year saw him at Venice, making a donation of his library to the republic of St Mark. Here his friend Boccaccio introduced him to the Greek teacher Leontius Pilatos. Petrarch, who possessed a MS. of Homer and a portion of Plato, never acquired the Greek language, although he attempted to gain some little knowledge of it in his later years. Homer, he said, was dumb to him, while he was deaf to Homer; and he could only approach the Iliad in Boccaccio's rude Latin version. About this period he saw his daughter Francesca happily married, and undertook the education of a young scholar from Ravenna, whose sudden disappearance from his household caused him the deepest grief. The youth had been identified, but on insufficient grounds, with that Giovanni Malpaghi of Ravenna who was destined to form a most important link between Petrarch and the humanists of the next age of culture. Gradually his oldest friends dropped off. Azzo di Coreggio died in 1362, and Laelius, Simonides, Barbato, in the following year. His own death was reported in 1365; but he survived another decade. Much of this last stage of his life was occupied at Padua in a controversy with the Averroists, whom he regarded as dangerous antagonists both to sound religion and to sound culture. A curious treatise, which grew in part out of this dispute and out of a previous duel with physicians, was the book U pon his own Ignorance and that of many others. At last, in 1366, tired with the bustle of a town so big that the best of it was hidden in the Arno, or in Euganean hills, where he continued his usual train of literary occupations, employing several secretaries, and studying unremittingly. All through these declining years his friendship with Boccaccio was maintained and strengthened. It rested on a solid basis of mutual affection and of common studies, the different temperaments of the two scholars securing them against the disagreements of rivalry or jealousy. One of Petrarch's last compositions was a Latin version of Boccaccio's story of Griselda. On the 18th of July 1374 his people found the old poet and scholar dead among his books in the library of that little house which looks across the hills and lowlands towards the Adriatic.

When we attempt to estimate Petrarch's position in the history of modern culture it is a fact which strikes us is that he was even less eminent as an Italian poet than as the founder of Humanism, the inaugurator of the Renaissance in Italy. What he achieved for the modern world was not merely to bequeath to his Italian imitators masterpieces of lyrical art unrivalled for perfection of workmanship, but also, and far more, to open out for Europe a new sphere of mental activity. Standing within the threshold of the middle ages, he surveyed the kingdom of the modern spirit, and, by his own inexhaustible industry in the field of scholarship and study, he determined what we call the revival of learning. By bringing the men of his own generation into sympathetic contact with antiquity, he gave a decisive impulse to that European movement which restored freedom, self-consciousness, and the faculty of progress to the human intellect. He was the first man to collect libraries, to accumulate coins, to advocate the preservation of MSS. For him the authors of the Greek and Latin world were living men—more real, in fact, than those with whom he corresponded; and the rhetorical epistles he addressed to Cicero, Seneca and Varro prove that he dwelt with them on terms of sympathetic intimacy. So far-reaching were the interests controlled by him in this capacity of humanist that his achievement as an Italian lyricist seems by comparison insignificant.

Petrarch's ideal of humanism was essentially a noble one. He regarded the orator and the poet as teachers, bound to complete themselves by education, and to exhibit to the world an image of perfected personality in prose and verse of studied beauty. Self-culture and self-effectuation seemed to him the highest aims of man. Everything which contributed to the formation of a free, impassioned, liberal individuality he regarded as praiseworthy. Everything which retarded the attainment of that end was contemptible in his eyes. The authors of antiquity, the Holy Scriptures and the fathers of the Church were valued by him as one common source of intellectual enlightenment. Eminently religious, and orthodox in his convictions, he did not seek to substitute a pagan for the Christian ideal. This was left for the scholars of the 15th and 16th centuries in Italy. At the same time, the Latin orators, historians and poets were venerated by him as depositories of a tradition only second in importance to revelation. For him there was no schism between Rome and Galilee, between classical genius and sacred inspiration. Though the latter took the first rank in relation to man's eternal welfare, the former was necessary for the perfection of his intellect and the civilization of his manners. With this double ideal in view, Petrarch poured scorn upon the French physicians and the Italian Averroists for their illiberal philostinism, no less than for their materialistic impiety. True to his conception of independent intellectual activity, he appealed from a legal or ecclesiastical important ecclesiastical office, and contented himself with paltry benefices which implied no spiritual or administrative duties, because he was resolved to follow the one purpose of his life—self-culture. Whatever in literature revealed the hearts of men was infinitely precious to him; and for this reason he professed almost a cult for St Augustine. It was to Augustine, as to a friend or a confessor, that he poured forth the secrets of his own soul in the book De contemptu mundi.

In this effort to realize his true self Petrarch was eminently successful. Much as he effected by restoring to the world a sound conception of learning, and by rousing that genuine love and curiosity which led to the revival, he did even more by impressing on the age his own full-formed and striking personality. In all things he was original. Whether we regard him as a priest who published poem after poem in praise of an adored mistress, as a pious man of letters who conversed on equal terms with kings and princes, as a solitary dedicated to the love of nature, as an amateur diplomatist treating affairs of state with pompous eloquence in missives sent to popes and emperors, or again as a traveller eager for change of scene, ready to climb mountains for the enjoyment of broad prospects over spreading champaigns; in all these divers manifestations of his peculiar genius we trace some contrast with the manners of the 14th century, some emphatic anticipation of the 16th. The defects of Petrarch were characteristic; he was no lover of theory, and were indeed their complement and counterpart. That vivid conception of intellectual and moral self-culture which determined his ideal took the form in actual life of all-absorbing egotism. He was not content with knowing himself to be the leader of the age. He claimed autocracy, suffered no rival near his throne, brooked no contradiction, demanded unconditional submission to his will and judgment. Petrarch was made up of contradictions. Praising solitude, playing the hermit at Vaucluse, he only loved seclusion as a contrast to the society of courts. While he penned dissertations on the futility of fame and the burden of celebrity he was trimming his sails to catch the breeze of popular applause. No one professed a more austere morality, and few medieval writers indulged in cruder satire on the female sex; yet he passed some years in the society of a concubine, and his living masterpiece of art is the apotheosis of chivalrous passion for a woman. These discords of an undecided nature displayed themselves in his political theories and in his philosophy of conduct. In one mood he was fain to ape the antique patriot; in another he affected the monastic saint. He was clamorous for the freedom of the Roman people; yet at one time he called upon the popes to re-establish themselves in the Eternal City; at another he besought the emperor to make it his headquarters; at a third he hailed in Rienzi the founder of a new republic. He did not perceive that all these plans were
incompatible. His relations to the Lombard nobles were equally at variance with his professed patriotism; and, while still a housemate of Visconti and Correggi, he kept on issuing invectives against the tyrants who divided Italy. It would not be difficult to multiply these antitheses in the character and the opinions of this singular man. But it is more to the purpose to remark that they were harmonized in a personality of potent and enduring force.

The point to notice in this complex personality is that Petrarch’s ideal remained always literary. As philosopher, politician, historian, essayist, orator, he aimed at lucid and harmonious expression—not, indeed, neglecting the importance of the material he undertook to treat, but approaching his task in the spirit of an artist rather than a thinker or a man of action. This accounts for his bewildering versatility, and for his apparent want of grasp on conditions of fact. Viewed in this light Petrarch anticipated the Italian Renaissance in its weakness—that philosophico-superficial character, that tendency to ornament rhetoric, that preoccupation with stylistic trifles, that want of profound conviction and stern sincerity, which stamp its minor literary products with the note of mediocrity. Had Petrarch been possessed with a passion for some commanding principle in politics, morality or science, instead of with the thirst for self-glory and the joy of being an object of veneration to posterity, it is not wholly impossible that Italian humanism might have assumed a manlier and more conscientious tone. But this is not a question which admits of discussion; for the conditions which made Petrarch what he was were already potent in Italian society. He did but express the spirit of the period he opened; and it may also be added that his own ideal was higher and severer than that of the illustrious humanists who followed him. As an author Petrarch must be considered from two points of view—first as a writer of Latin verse and prose, secondly as an Italian lyricist. In the former capacity he was specially outstripped by a score of more fortunate scholars. His eclogues and epistles and the epic of Africa are no more than the expression of a consummate art. If he can exhibit a comparatively limited command of Latin metre. His treatises, orations, and familiar letters, though remarkable for prose style which is eminently characteristic of the man, are not distinguished by purity of diction. Much as he admired Cicero, it is clear that he had not freed himself from current medieval Latinity. Seneca and Augustine had been too much used by him as models of composition. At the same time it will be conceded that he possessed a copious vocabulary, a fine ear for cadence, and the faculty of expressing every shade of thought or feeling. What he lacked was that insight into the best classical masterpieces, that command of the best classical diction, which is the product of successive imitations and attacks of the master that informs, and these imitations, and these attacks, as much as an Italian school of the 14th century, as it is unfair to ascribe to him the phrase of the Latin poet, "Imitation is the mother of poetry." He was not anxious to make the name of Petrarchist into contempt, we can agree with Shelley that the lyrics of the Canzoniere "are as spells which unseen the immost enchanteds of the delight which is the grief of love." Much might be written about the peculiar position held by Petrarch between the metaphysical lyrists of Tuscany and the more realistic amorists of succeeding generations. True in this respect also to his anticipation of the coming age, he was the first Italian poet of love to free himself from allegory and mysticism. Yet he was far from approaching the analysis of emotion with the directness of a Heine or De Musset. Though we believe in the reality of Laura, we derive no clear conception either of her character or of her love. She is not so much a woman as woman in the abstract; and perhaps on this very account the poems written for her by her lover have been taken to the heart by countless lovers who came after him. The method of his art is so generalizing, while his feeling is so natural, that every man can see himself reflected in the singer and his mistress shadowed forth in Laura. The same criticism might be passed on Petrarch’s descriptions of nature. That he felt the beauties of nature keenly is certain, and he frequently touches them with obvious appreciation. Yet he has written nothing so characteristic of Vaucluse as to be inapplicable to any solitude where there are woods and water. The Canzoniere is therefore one long melodious monody poured out of the poet’s soul, with the indefinite form of a beautiful woman seated in a lovely landscape, a perpetual object of delightful contemplation. This disengagement from local circumstances without the sacrifice of emotional sincerity is a merit in Petrarch, but it became a fault in his imitators. Lacking his intensity of passion and his admirable faculty for seizing the most evanescent shades of difference in feeling, they degenerated into colourless and lifeless insipidities made insupportable by the rigid repetition of tropes and conceits which we are fain to pardon in the master.

Petrarch did not distinguish himself by love-poetry alone in the Italian language. His odes to Giacomo Colonna, to Cola di Rienzo, to the Priests of the Holy Ghost, and to his own mother’s copy of the De remediis, are of far less importance. They exhibit the ornamental fervour, the pleader’s eloquence, to which the most perfect lustre, which Petrarch possessed in no less measure than subjective passion. Modern literature has nothing nobler, nothing more harmonious in the declaratory style than these three pathetic effusions. Their spirit itself is epoch-making in the history of Europe. Up to this point Italy had scarcely begun to exist. There were Florentines and Lombards, Guelfs and Gibellines; but even Dante had scarcely conceived of Italy as a nation, independent of the empire, inclusive of her several component commonwealths. To the high conception of Italian nationality, to the belief in that spiritual unity which underlay her many discords and divisions, Petrarch attained partly through his own greatness of soul and mind, partly through his large and liberal ideal of culture.

The materials for a life of Petrarch are afforded in abundance by his letters, collected and prepared for publication under his own eyes. These are divided into Familiaria Correspondence, Correspondence in Old Age, Diaries Letters and Letters without a Title; to which may be added the curious autobiographical fragment entitled Epistle to Posterity. Next in importance rank the epistles and eclogues in Latin verse, the Italian poems and the rhetorical ad- dress, the special treatises, and the historical monuments. For the comprehension of his character the treatise De contemptu mundi; addressed to St Augustine and styled his Secret, is invaluable. Without attempting a complete list of Petrarch’s works, it may be well to illustrate the extent of his erudition and his activity as a writer by a brief enumeration of the most important. In the section belonging to moral philosophy, we find De remediis utissimae fortunae, a treatise on human happiness and its conditions, a De medicina, a De vita humana medicorum, a De viris illustribus, an epitome of the biographies of Roman worthies. Three polemical works require mention: Contra cujusdam anonymini Gesta, an apologia, Contra medicum quendam instituturum, et De suis usu rebus medici, a criticism and sarcastic compositions, which grew out of Petrarch’s quarrels with the physicians of Avignon and the Averoists of Padua. In this connexion it might also be well to mention the remarkable
satisfies the papal court, included in the Epistolae sine titulo. Five public orations have been preserved, the most weighty of which is the speech delivered on the Capitol upon the occasion of his coronation. Among his Latin poems Africa, an epic on Scipio Africanus, takes the first place. Twelve Elogiums and three books of Epistles in verse close the list. In Latin he wrote, however, another poem in the form of an oration which includes odes and sonnets written for Laura during her lifetime, those written for her after her death, and a miscellaneous section containing the three patriotic odes and three famous poetical invectives against papal courtiers. The latter compositions are the semi-epic or allegorical Trionfi—Triumphs of Love, Chastity, Death, Fame, Time and Divinity, written in terza rima of smooth and elegant quality. Though these Triumphs, as a whole, are deficient in poetic inspiration, the second and the fourth of the Trionfi della morte, in which Petrarch describes a vision of his dead love Laura, is justly famous for reserved passion and pathos touchingly mingled with melancholy.

The complete bibliography of Petrarch forms a considerable volume. Such a work was attempted by Domenico Rossetti (Trieste, 1828). It will be enough here to mention the Basel edition of 1581, in folio, as the basis for all subsequent editions of his collected works. Among editions of the Canzoniere special mention may be made of those of Marsand (Padua, 1820), Leopardi in Le Monnier’s collection, Medicea (1849), and Cardini (1899). Nor must Frauscetti’s Italian version of the Letters (published in 5 vols. by Le Monnier) be neglected. De Sad’s Life of the poet (Amsterdam, 1764-1767) marks an epoch in the history of his biographies; but this is in many important points untrustworthy, and many of the dates are incorrect. Gustav Kurtin’s exhaustive volume on Petrarch’s Leben und Werke (Leipzig, 1878). Georg Voigt’s Wiederbelebung des klassischen Alterthums (Berlin, 1895) contains a critical estimate of his work in relation to the revival of learning. Mzieri’s Petrarcha (1868) is a monograph of merit. English readers may be referred to a little book on Petrarch by Henry Reeve, and to vols. ii. and iv. of Symonds’s Renaissance in Italy (1882). See also Maud F. Jerrold, Francesco Petrarcha, humanist (1900).

PETRE, SIR EDWARD (1651-1699). Jesuit manuscripts of King James II. of England, of which a part was in Paris. He was the son of Sir Francis Petre, Bart., of Cranham, head of a junior branch of the family of the Barons Petre, and his wife Elizabeth Gage, daughter of Sir John Gage, both strong Roman Catholics. In 1649 he was sent for his education to the Jesuit College at St Omer, and he entered the order under the name of Spencer in 1652, but did not receive the full orders till 1671. In 1679 he succeeded his elder brother in the title and family estates. On the accession of James II. in 1685 he was chosen as confessor by the king, who looked upon him as "a resolute and undertaking man. During the whole of the king’s reign Petre was one of his advisers who did the most to encourage him in the policy which ended by producing the revolution of 1688. The king considered him as a great friend to the archbishop, and then vacant, but the pope, Innocent XI., who was not friendly to the order, would not grant a dispensation to hold it, and even directed Petre’s superiors to rebuke him for his excessive ambition. In 1687 he was made privy councillor. When the revolution broke out Petre was compelled to flee disguised as a woman. After his flight he had no further relations with James II. After a visit to Rome, he became head of the Jesuit College at St Omer in 1683, from whence he was transferred to Walten in Flanders in 1697. He died on the 15th of May 1699. A younger brother Charles (1614-1712) was also a member of the order.

PETRE, SIR WILLIAM (c. 1595-1677). English politician, was a son of John Petre, a Devon man, and was educated at Exeter College, Oxford, afterwards becoming a fellow of All Souls’ College. He entered the public service in early life, owing his introduction therein doubtless to the fact that at Oxford he had been tutor to Anne Boleyn’s brother, George Boleyn, Viscount Rochford, and began his official career by serving the English government abroad. In 1536 he was made deputy, or proctor, for the vicar-general, Thomas Cromwell, and as such he presided over the convocation which met in June of this year. In 1543 Petre was knighted and was appointed a secretary of state; in 1545 he was sent as ambassador to the emperor Charles V., where, in the capacity of ambassador under Edward VI. and also under Mary, forsaking the protector Somerset at the right moment and winning Mary’s goodwill by favouring her marriage with Philip II. of Spain. He resigned his secretariaship in 1557, but took some part in public business under Elizabeth until his death at his residence, Ingatstone, Essex, on the 13th of January 1572.

His son John Petre (1549-1613) was created Baron Petre of Writtle in 1603. The 2nd baron was his son William (1575-1657), whose grandson was William, the 4th baron (c. 1626-1684). Denounced by Titus Oates as a papist, the last named was arrested with other Roman Catholic noblemen in 1678 and remained without trial in the Tower of London until his death. His brother John (1629-1684) was the 5th lord, and the latter’s nephew, Robert (1689-1713), was the 7th lord. It was Robert’s action in cutting a lock of hair from a lady’s head which led Pope to write his poem “The Rape of the Lock.” The Petres have been consistently attached to the Roman Catholic faith, William Joseph, the 13th baron (1838-1903), being a priest of the Roman church, and the barony is still (1911) in existence. One of the 1st baron’s grandsons was William Petre (1602-1677), who translated the Pio sanctorum of Pedro de Ribadeniera as Lives of the Saints (St Omer, 1669, London, 1736).

PETREL, the general name of a group of birds (of which more than 100 species are recognized), derived from the habit which some of them possess of apparently walking on the surface of the water as the apostle St Peter (of whose name the word is a diminutive form) is recorded (Matt. xiv. 20) to have done. The petrels, all of which are placed in the family Procellaridae, were formerly associated with the Laridae (see GULL), but they are now placed as the sole members of the suborder Tubinares (the name denoting the characteristic tubular structure of their nostrils) and of the order Procellariiformes (see BIRD). They are subdivided into four groups or subfamilies: (1) Pterodroma (or Halodromiinae), containing some three or four species known as diving-petrels, with habits very different from others of the family, and almost peculiar to high southern latitudes from Cape Horn to New Zealand; (2) Procellariinae, or petrels proper (and shearwaters); (3) Diomedeinae, or albatrosses (see MALLEMSCUCK); and (4) Oceanitinae, containing small sooty-black birds of the genera Cynodromia, Pedola, Pedagordoa, Garrudia and Oceanites, the distinctive nature of which was first recognized by Cuvier in 1824.

Petrels are archaic oceanic forms, with great powers of flight, dispersed throughout all the seas and oceans of the world, and some species are never seen excepting for the purpose of nidification, though nearly all are liable at times to be driven ashore, and often very far inland, by gales of wind. It would also seem that during the breeding-season many of them are wholly nocturnal in their habits, passing the day in holes of the ground, or in crevices of the rocks, in which they generally nestle, the hen of each pair laying a single white egg, sparsely speckled in a few species with fine reddish dots. Of those species that frequent the North Atlantic, the common Storm-petrel, Procellaria pelagica, a little bird which has to the ordinary eye rather the look of a Swift or Swallow, is the largest, and unlike Carey’s chicken "of sailors, and is widely believed to be the harbinger of bad weather: but seamen hardly discriminate between this and others nearly resembling it in appearance, such as Leach’s or the Fork-tailed Petrel, Cyanorhynchus leucorhoa, a rather larger but less common bird, and Wilson’s Petrel, Oceanites oceanicus, the type of the Family Oceanitidæ mentioned above, which is more common on the American side. But it is in the Southern Ocean that Petrels most abound, both as species and as individuals. The Cape-Pigeon or Pintado Petrel, Daption capensis, is one that has long been well known to mariners and other wayfarers on the great waters, while those who voyage to or from Australia, whatever be the route they take, are...
certain to meet with many more species, some, as Oasifraga gigantea, as large as Albatrosses, and several of them called by sailors by a variety of choice names, generally having reference to the strong smell of music emitted by the birds, among which that of "Stink-pot" is not the most opprobrious. None of the Petrels are endowed with any brilliant colouring—sooty-black, grey of various tints (one of which is often called "blue"), and white being the only hues the plumeage exhibits.

The distribution of the several species of Petrels in the Southern Ocean has been worked out by A. Milne-Edwards in his "Recherches sur les sciences naturelles pour 1882" (6th series Zoologique, vol. xliii. art. 4, pp. 1-22).

PETRIE, GEORGE (1790-1866), Irish antiquary, was the son of James Petrie, a native of Aberdeen, who had settled in Dublin as a portrait and miniature painter. He was born in Dublin in January 1790, and was educated as an artist. Besides attaining considerable reputation as a painter of Irish landscape, he devoted much time to the illustration of the antiquarian and historical section of the ordnance survey of Ireland. In 1832 he became editor of the Dublin Penny Journal, a periodical designed to disseminate information among the masses, to which he contributed numerous articles on the history of the fine arts in Ireland. Petrie may be regarded as the first scientific investigator of Irish archaeology, his contributions to which are also in themselves of much importance. His Essay on Round Towers, for which in 1830 he received the prize of the Irish Academy, still ranks as a standard work. Among his other contributions to Irish archaeology are his Essay on the Military Architecture of Ireland and his Monuments and Antiquities of Tara Hill. He died on the 17th of January 1866.

See the Life and Labours in Art and Archaeology of George Petrie, by William Stokes (1868).

PETRIE, WILLIAM MATTHEW FLINDERS (1853- ), English Egyptologist, was born at Charlton on the 3rd of June 1853, being the son of William Petrie, C.E. His mother was the daughter of Captain Matthew Flinders, the Australian explorer. He took an early interest in archaeological research, and between 1875 and 1880 was busily engaged in studying ancient British remains at Stonehenge and elsewhere; in 1880 he published his book on Stonehenge, with an account of his theories on this subject. He was also much interested in ancient weights and measures, and in 1875 published a work on Inductive Metrology. In 1881 he began a long series of important surveys and excavations in Egypt, beginning with the pyramids at Giza, and following up his work there by excavations at the great temple at Tanis (1884), and discovering and exploring the long-lost Greek city of Naukratis in the Delta (1883), and the towns of Am and Daphnae (1886), where he found important remains of the time when they were inhabited by the Pharaohs. Between 1888 and 1890 he was at work in the Fayum, opening up Hawara, Kahun and Lachish; and in 1891 he discovered the ancient temple at Medum. Much of this work was done in connexion with the Palestine Exploration Fund. By this time his reputation was established. He published in 1893 his Ten Years' Diggings in Egypt, was given the honorary degree of D.C.L. by Oxford, and was appointed Edwards Professor of Egyptology at University College, London. In 1894 he founded the Egyptian Research Account, which in 1905 was reconstituted as the British School of Archaeology in Egypt (not to be confused with the Egypt Exploration Fund, founded 1882). Perhaps the most important work which the School has accomplished has been the investigation of the site of Memphis (p.c.)

The extent as well as the chronological order of Professor Petrie's excavations may best be shown by a list of his works.

Tell el Amarna (1865); Kopou (1866); Noguda (1866); Six Temples at Thebes (1869); Desheesh (1870); Denderat (1890); Deir el Medina and the process was destroyed on first (1890); Royal Tombs of the Earliest Dynasties (1901); Hyksos and Israelite Cities (1906); Religion of Ancient Egypt (1906); Personal Religion in Egypt (1898). On particular sites, Pyramids and Temples of Gizeh (1883); Tanis I. (1885); Naqetpis I. (1886); Hawara (1888); Kahun (1890); Ililben (1894); Medum (1892);
name of "Seneca oil," and the "American Medicinal Oil" of Kentucky was largely sold after its discovery in 1829. The Pennsylvania Rock Oil Company was formed in 1854, but its operations were unsuccessful, and in 1857 certain of the members founded the Seneca Oil Company, under whose direction E. L. Drake started a well on Oil Creek, Pennsylvania. After drilling had been carried to a depth of 69 feet, on the 28th of August 1859, the tools suddenly dropped into a crevice, and the following day the well was found to have "struck oil."

This well yielded 25 barrels a day for some time, but at the end of the year the output was at the rate of 15 barrels. The production of crude petroleum in the United States was officially reported to have been 2000 barrels in 1859, 4,215,000 barrels in 1869, 19,914,146 barrels in 1879, 35,163,513 barrels in 1889, 57,084,428 barrels in 1899, and 126,493,936 barrels in 1906. From Oil Creek, development spread first over the eastern United States and then became general, subsequently embracing Canada (1862), recently discovered fields being those of Illinois, Alberta and California (44,854,757 barrels in 1908).

For about 10 years Pennsylvania was the one great oil producer of the world, but since 1870 the industry has spread all over the globe. From the time of the completion on the Baku field of the first flowing well (which was unmanageable and resulted in the loss of the greater part of the oil), Russia has ranked second in the list of producing countries, whilst Galicia and Rumania became prominent in 1878 and 1880 respectively. Sumatra, Java and Borneo, where active development began in 1883, 1886 and 1896, bid fair to rank before long among the chief sources of the oil supplies of the world. Similarly, Burma, where the Burma Oil Company have, since 1899, rapidly extended their operations, is rising to a position of importance. Oil fields are being continually opened up in other parts of the world, and whilst America still maintains her position as the largest petroleum producer, the world's supplies are now being derived from a steadily increasing number of centres.

Physical and Chemical Properties.—Although our information respecting the chemical composition of petroleum has been almost entirely gained since the middle of the 18th century, a considerable amount of empirical knowledge of the substance was possessed by chemists at an earlier date, and there was much speculation as to its origin. In his Syra zylyarn (1627), Francis Bacon states that "the original concretion of bitumen is found under the rocks and is called in the languages of that country "the substance that "attracts" the naphtha of Babylon "aer analytic." P. J. Macquer (1764), T. O. Bergman (1784) Charles Hatchett (1798) and others also expressed views with regard to the constitution and origin of bitumens. Of these early writers, Hatchett is the most explicit, the various bituminous substances being by him classified and defined. Jacob Joseph Winternitz, in 1788, appears to have been the first to examine petroleum chemically, but the earliest systematic investigation was that carried out by Professor B. Stillman, Jun., in 1855, who then reported upon the results which he had obtained with the "rock oil or petroleum of Veneango county, Pennsylvania."

This report has a very classic in the history of petroleum. The physical properties of petroleum vary greatly. The colour ranges from pale yellow through red and brown to black or greenish, while by reflected light it is, in the majority of cases, of a green hue. The specific gravity of crude petroleum appears to range from 0.771 to 1.06, and the flash point from below 0° to 370° F. Viscosity increases with density, but oils of the same density often vary greatly; the coefficient of expansion, on the other hand, varies inversely with the density, but bears no simple relation to the change of fluidity of the oil under the influence of heat, this being most marked in oils of paraffin base. The calorific power of Baku oil appears to be highest, whilst the lowest figures in solid hydrocarbons, of which the American petroleums contain moderate quantities, and the Upper Burma oils the largest amount. The boiling point, being determined by the character of the constituents of the oil, necessarily varies greatly in different oils, as do the amounts of distillate obtained from them at specified temperatures.

Even prior to the discovery of petroleum in commercial quantities, a number of chemists had made determinations of the chemical composition of various different varieties, and these investigations, supplemented by those of a later date, show that petroleum consists of about 84% by weight of carbon with 12% of hydrogen, and varying proportions of sulphur, nitrogen and oxygen. The principal elements are found in various combinations in the Pennsylvania oils being mainly paraffins (q.v.), while those of Caspian and Russian origin are for the most part the naphthenes, isomer with the olefines (q.v.).

Paraffins are found in all crude oils, and olefines in varying proportions in the majority, while acetylene has been found in Baku oil; members of the benzene group and its derivatives, notably benzene and toluene, occur in all petroleums. Naphthenes are the chief components of some oils, as already indicated, and occur in varying quantities in many others. Certain crude oils also have been found to contain camphene, napthalene and other aromatic hydrocarbons. It is found that transparent oils under the influence of light absorb oxygen, becoming deeper in colour and opalescent, while strong acidity and a penetrating odour are developed, these changes being due to the formation of various acid and phenylated compounds, which are also occasionally found in fresh oils. The residues from petroleum distillation have been shown to contain very dense solids and liquids of high specific gravity, having a large proportion of carbon and possessed of remarkable fluorescent properties.

Natural gas is found to consist mainly of the lower paraffins, with varying quantities of carbon dioxide, carbon monoxide, hydrogen, nitrogen and oxygen, in some cases also sulphurated hydrogen and possibly ammonia. This mixture dissolves in petroleum, escaping when the oil is stored, and conversely it invariably carries a certain amount of water and oil, which is deposited on compression.

Occurrence.—Bitumen is, in its various forms, one of the most widely-distributed of substances, occurring in strata of every geological age, from the lowest Archean rocks to those now in process of deposition, and in greater or less quantity throughout both the northern and southern continents. Some regions, however, such as California to Japan. The occurrence of commercially valuable petroleum is, however, comparatively limited, hitherto exploited deposits being confined to rocks younger than the Cambrian and older than the Quaternary, while the majority of developed oilfields have been discovered north of the equator.

The main requisite for a productive oil or gas field are a porous formation and an imperious cover. Thus, while the mineral may be formed in a stratum other than that in which it is found, though in many cases it is indigenous to it, for the formation of a natural reservoir of the fluid (whether liquid or gas) it is necessary that the rock and be a sufficient supply of oil trapped. The main rock is typically exemplified by a coarse-grained sandstone or conglomerate, while a limestone may be naturally porous, or, like the Trenton limestone of Ohio and Indiana, rendered so by its conversion into dolomite by contact with carbonate of lime due to shrinkage—a change occurring only in the purer limestones. Similarly it is necessary, in view of the hydrostatic relations of water and mineral oils, and the volatile character of the latter, that the porous stratum should be protected from water, and conversely be an overlying shale or other impervious deposit. Water, often saline or sulphurous, is also found in these porous rocks and replaces the oil as the latter is withdrawn.

In addition to these factors, structural conditions play an important part in determining the accumulation of oil and gas. The main supplies have been obtained from strata classified as anticlinal or synclinal and comprising a mass of anticlinal or terrace structure, however slightly marked or limited in extent, exerts a powerful influence on the creation of reservoirs of petroleum. These tectonic arches often extend for long distances, and are sometimes great ranges of anticlinal and synclinal antelimes, which themselves play a not unimportant part in the aggregation of the oil. Owing to difference of density the oil and water in the anticlines separate into two layers, the upper containing the lighter oil which is separated from the water by a "terrace" of a type of structure, a "deflation" with a deceiving action at that part being sufficient only to arrest the descent which would otherwise occur. The terraces may thus be regarded as flat and extended anticlines. They need not be horizontal, and sometimes have a dip of a few feet per mile, as in the case of the Ohio and Indiana oil fields, where the amount varies from
PETROLEUM

one to ten feet. These slight differences in level, however, are found to have a most powerful effect in the direction already mentioned.

The resident that accurate knowledge of the character and structure of the rock-formations in petroliferous territories is of the greatest importance in enabling the expert to select favourable sites for drilling operations; hence on well-conducted petroleum-prospecting expeditions the colony, or country, that makes the most of the strata perforated by the drill, so that a complete section may be prepared from the recorded data. In some cases the depths are stated with reference to sea-level, instead of being taken from the surface, and largely facilitates the utilization of the records.

Oil and gas are often met with in drilled wells under great pressure, which is highest as a rule in the deepest wells. The closed pressure in the Trenton limestone in Ohio and Indiana is about 200—300 lb. per square inch, although a higher pressure has been registered in many wells. The gas wells of Pennsylvania indicate about double the pressure of those drilled in the Trenton limestone, 600—900 lb. per square inch, but has been going down. The extremely high pressure under which oil and gas have met with in drilled wells in some parts of the Russian oil fields is a matter of common knowledge, and a fountain or spouting well resulting therefrom is one of the "sights" of the country. A famous fountain in the Groznny oil field in the northern Caucasus, which began to flow in August 1895, was estimated to have thrown up during the first three days 1,200,000 poods (over 4,500,000 gallons, or about 18,000,000 lb.) of oil. It has now been gradually diminishing quantity, for fifteen months; afterwards the flow became intermittent. In April 1897 there was still an occasional outburst of oil and gas.

Three theories have been propounded to account for this pressure:

1. That it results from the weight of the overlying strata.
2. That it is the result of pressure, as in artesian wells ("hydrostatic" or "artesian" theory).
3. That it is caused by the compressed condition of the gradually accumulating gas.

Of these the first has been proved untenable, and while in some instances (e.g. certain wells in Ohio), the second has held good, the third appears to be the most widely applicable.

The conditions of formation and accumulation of petroleum probably influence the principal of the work done by the water in the reservoirs, which will become exhausted in the course of years, as in the case of the decreasing yield of certain of the American fields. But new deposits are continually being exploited, and there may be found in the future other opinions which will ultimately determine the method that might be expressed at the present time in regard to the probable duration of the world's supply of oil and gas.

As already stated, every one of the great geological systems appears to have produced some form of bitumen, and in the following table an attempt has been made to classify on this basis the various localities in which petroleum or natural gas has been found in large or small quantities:

<table>

In the United States, petroleum was discovered in the 19th century, with major fields in Ohio, Pennsylvania, and New York. The oil boom of the 1890s and early 1900s led to the development of new fields in Texas, Oklahoma, and California.

The question of the origin of petroleum (and natural gas), though for the first half of the 19th century little more than academic interest, has engaged the attention of naturalists and others for over a hundred years. As early as 1804, Humboldt suggested that petroleum might have been produced by the decay of vegetable matter. The French geologist Reichenbach in 1834, suggested that the oil came from the action of heat on the turpentine of pine-trees, whilst Brunet in 1836, advanced a similar theory of the origin of gas on the ground of certain laboratory experiments. The theories propounded may be divided into two groups, namely, those ascribing to petroleum an inorganic origin, and those which regard it as the result of the decomposition of organic matter.

M. P. E. Berthelot in 1866, after conducting a series of experiments, that mineral oil was produced by purely chemical action, similar to that employed in the manufactory of stearine, and that the carbon and other residues of the water brought forward by various chemists, Mendeleef, and others, that the formation of petroleum to the action of water at high temperatures on iron carbide in the interior of the earth.

The increasing majority of those who have studied the natural conditions under which petroleum occurs are of opinion that it is of organic origin. The earlier supporters of the organic theory held that it was a product of the natural decomposition of coal or carbonaceous matter; but though in a few instances volcanic intrusions appear to have converted coal or allied substances into oil, it seems that terrestrial vegetation does not generally give rise to petroleum. Among those who have opposed the organic theory, it is held that the decomposition of water and vegetable organisms may be mentioned J. P. Lesley, E. Orton and S. F. Peckham, but others have held that it is of exclusively animal origin, a view supported by such occurrences as the presence of the orthocerates in the Cretaceous rocks of Turkey, and the experiments of C. Engler, who obtained a liquid like crude petroleum by the distillation of menhaden (fish) oil. Similarly there is a difference of opinion as to the conditions under which the organisms have been mineralized, some holding that the process has taken place at a high temperature and under great pressure; but the lack of practical evidence in nature in support of these views has led many to conclude that petroleum, like coal, has been formed under conditions of lower temperature and pressure, and at a shallower depth of the containing rocks. This view is supported by the fact that petroleum is found on the Sardinian and Swedish coasts as well as in the interior of the land. The deposits of petroleum are seaward, heated only by the sun, and under atmospheric pressure.

Consideration of the evidence leads us to the conclusion that, at least in commercially valuable deposits, mineral oil has generally been formed by the decomposition of marine organisms, in some cases animal, in others vegetable, in others both, under practically normal conditions of temperature and pressure.
The drilling tools are suspended by an unarrested manila rope, 2 in. in diameter, passing from the bull-wheel shaft over a grooved pulley. At the other end of the shaft is a hand-wheel of the old-fashioned type, as at the base of the Derrick. The string of drilling tools consists of two parts separated by an appliance known as the jars.

This piece of apparatus was introduced by William Morris in 1831. In addition to the jars, the drillers mentioned the tools for enlarging the bore of the well, the winged-substitute, which is fitted above the bit to prevent it from glancing off, and above the round reamer to keep it in place, a temper-screw with a box-up plate.

The action of the jars and temper-screw has been described by John F. Curll as follows: Suppose the tools to have been just brought up to the surface and let out of the well. The men now take hold of the bull-wheels and draw up the slack of the wire until the rotator rises. The 'play' of the jars allows it to come up 13 ft., without disturbing the auger-stem. When the jars come together they slack back about 4 in., and the cable is in position to be clamped in the temper-screw. If now the vertical movement of the walking-beam is 24 in., when it starts on the up-stroke the jars always set in reverse. As the cross-beam comes together with a smart blow, then the auger-stem is blocked up about 4 ft. On the down-stroke, the auger-stem falls 20 in., while the sinker-bar goes down 24 in. to telescope the jars for the next blow coming up. Thus the weight of the jars, together with the vertical pressure, is used without a blow. Whatever the length of stroke, they are only used to jar down when the tools stick on some obstruction in the well before reaching the bottom, and in fishing operations. An unskilled workman sometimes loses the jars and works for hours without accomplishing anything. The top is made to stand at the bottom while he is playing with the slack of the cable or they may be swinging all the time several feet from the bottom. As the jars works off, or grows more feeble, by reason of the downward advance of the drill, it is 'tempered' to the proper strength by letting down the temper-screw to give the jars more play. The temper-screw forms the connecting link between the walking-beam and cable, and it is 'let out' gradually to regulate the upward or downward movement of the jars.

The length of the walking-beam and the rope is made up of some 300 ft. of link-cords, or links. Without the weight of fishing tools are provided. These are so numerous and varied in form, that a description would be impossible within the scope of this article. The fishing tools are generally attached to the cable, and are used with portions of the ordinary string of tools, but some are fitted to pump-rods or tubing, and others to special rods.

The drilling of a well is commonly carried out under contract, the drilling contractor working under a lease with the owner of well, while the drilling contractor finds the tools, and is responsible for accidents or failure to complete the well. The drilling crew consists of two drillers, two oilers, and two pairs of two 'tours' (noon to midnight and midnight to noon).

The earlier wells in Pennsylvania consisted of three sections, the first formed of surface clays and gravel, the second of rock containing water, and the third of stratiified rocks, including the oil-sands, usually free from water. The conductor, which was a wooden casing of somewhat greater internal diameter than the maximum bore of the well, passed through the center and was used to prevent percolation of water into the oil-bearing portion. In later wells the conductor has been replaced with a 8-in., wrought-iron drive-pipe, terminating in a plug at the bottom. In the drilling of an oil-well, the conductor is drilled below it to the base of the lowest water-bearing stratum. The bore is then reduced to 3½-in., and a bevelled shoulder being made in the rock, a 5½-in. casing, having a collar to fit water-tight into the well, is run in and a shoulder is bored in to fit a 4½-in. bit. As the water is shut off before the portion of the well below the water-bearing strata is bored, the remainder of the drilling is conducted with only sufficient water in the well to
PETROLEUM

The drill is thus allowed to fall freely, instead of being partly upheld by the buoyancy of the water, as in earlier wells.

While Pennsylvania now range in depth from 300 ft. to 3700 ft. Four strings of iron casing are usually employed, having the following diameters: 10 in., 8½ in., 6 in. and 5 in., the lengths of tube forming the casing being screwed together. Contractors will often underbore the well to a moderate depth, and then lower the core of casing about 8 ft. into the well, but the cost of a deep well may amount to as much as $7000.

The rotary system of drilling which is in general use in the oilfields of the coastal plain of Texas is a modification of that invented by H. C. White, of the early 1840's. It is one of the most rapid and economical which can be employed in soft formations, but where hard rock is encountered the employment of a multiple of toothed organs is generally used. The drilling organ consists essentially in the use of rotating hollow drilling rods or casing, to which is attached the drilling-bit and through which a column of water, under a pressure of 40 to 100 lb. per sq. in., is forced.

The yield of petroleum wells varies within very wide limits, and the relative importance of the different producing districts is also constantly changing. I. C. White, state geologist of

Yield of Wells.

West Virginia, estimates that in fairly good producing sand a cubic foot of rock contains from 6 to 12 pints of oil. He assumes that in what is considered a good producing district of the petroleum region of that state the average thickness of a cubic foot of rock would not be more than a gallon, and that the average thickness of the oil-bearing rock would not exceed 5 ft. Taking these figures as a basis, the total yield of oil from an acre of the rich oil district of the state would be about 5000 barrels of 42 U.S. gallons.

A flow of oil may often be induced in a well which would otherwise remain dry and non-productive by the introduction of water, the oil being displaced or driven to its surface. The device employed for this purpose is known as the water-packer, and consists in its simplest form of an India-rubber ring, which is applied between the tubing and the well-casing, so that upon compression it makes a tight joint. The gas thus confined in the oil-chamber forces the oil up the tubing.

For pumping a well a valved working-barrel with valve-sucker is used, and the operation it is not until the valve is opened after the water-packer has been placed below. The sucker carries a series of three or four leather caps, which are pressed against the inner surface of the working-barrel by the weight of the column of oil. The sucker is connected by a string of sucker-rods with the walking-beam. There is usually fixed above the sucker a short iron valve-rod, with a device known as a rivet-catcher to prevent damage to the pump by the dropping of rivets from the pump-rods.

On the completion of drilling, or when the production is found to decrease, it is usual to torpedo the well to increase the flow.

Torpedoing Wells.

The explosive employed is generally nitroglycerin, and is used at different depths at original 4 to 6 quarts to 60, 80, and even 200 quarts. It is placed in tin canisters of about 3½ to 5 in. in diameter and about 10 in. in length. The canisters have conical bottoms and flared tops, and are filled with nitroglycerin, and are lowered to the bottom of the well, one after the other, by a cord wound upon a reel, until the required number have been inserted. Formerly the upper end of the highest canister was closed with a flat metal cap known as a noose, or deadhead, but this method is now generally abandoned. The lower end of the first canister is almost invariably employed. The disk is dispensed with, and the percussion cap is exploded by the impact of a leaden weight running over the top of the canister, or by the blow of the descending weight, and when exploded by the descent of the weight, fires the charge. It must be borne in mind that although the explosion may increase the production for a time, it is by no means certain that the ascending current of gas and the weight of the gas being driven upward from some wells there would be no production without the use of the torpedo.

The petroleum industry in Canada is mainly concentrated in three districts, Pennsylvania, Ontario, and the extensive field of the Oil Creek and Allegheny river.

1. The use of slender wooden boring-rods instead of a cable.
2. The employment of a simple auger instead of a spudding-bit.
3. The adoption of a different arrangement for transmitting motion.
4. The use of a lighter set of drilling tools.

Although petroleum wells in Russia have not the depth of many

of those in the United States, the disturbed character of the strata, with consequent liability to caving, and the occurrence of hard concretions, render drilling a lengthy and expensive business. In 1887 it was estimated that one day's drilling in Russia cost $700 to $800, or in American currency about $2000. The initial depth of some wells has been as much as 900 ft. or more, with the result that the well has become choked, and admits of the use of larger boilers for raising the oil.

The drilling of wells of large size requires the use of heavy tools and very strong appliances generally. The system commonly adopted is a modification of the Canadian system already described, the boring rods being, however, of iron instead of wood, but the casing or some extent has been extensively used. For the ordinary 2-in. plain-laid manila cable a wire rope has in some cases been successfully substituted.

Riveted iron casing, made of 3½-in. plate, is employed, and is connected so that it is fixed to the well casing, but not tied so tightly as to prevent caving. Within recent years, owing to the initiative of Colonel English, a method of raising oil by the agency of compressed air has been introduced into the Bakou oil-fields.

In Galicia the Canadian system is nearly exclusively adopted. In some instances under-reaming is found necessary. This consists in the use of an expanding reamer by means of which the well may be drilled to a diameter of 10 in., or 10,000 ft. Drilling operations are generally accomplished with an ordinary bit introduced through the casing. Of late years the under-reamer has been largely superseded by the eccentric bit.

The Davis calyx drill has also been employed for petroleum drilling. This apparatus may be described as a steel-pointed core-drill. The bit or cutter consists of a cylindrical iron shell, the interior of which is filled with oil, thus forming a process of gulling, into a series of sharp teeth, which are set in and out alternately. The outward set of teeth drill the hole large enough to permit the drilling apparatus to descend freely, and the teeth set inwardly pare down the core to such a diameter as will admit of the body of the cutter passing over it without seizing. The calyx is a long tube, or a series of connected tubes, situated above the core barrel, to which it is equal in diameter.

The method of drilling for petroleum with which by far the largest amount of work has been, and is being done, are the American or rope Comparison system, and the Canadian or rod system. The former of Systems. Systems has been adopted in Upper Burma, Java, Rumania and elsewhere. The latter was introduced by Canadians into Galicia and, with certain modifications, has hitherto been found to be the best for that country. A form of the rod system is used in the Russian oil-fields, but owing to the large diameter of the wells the appliances differ from those employed elsewhere.

The crude oil from wells where supplies of natural gas are obtained in the United States are drilled and cased in the same manner as the wells.

Transport and Storage.—In the early days of the petroleum industry in America the wells were usually worked by hand. Thus, in Upper Burma, it was conveyed in earthenware vessels from the wells to the river bank, where it was poured into the holds of boats. It is interesting to find that a rude pipe-line formerly existed for carrying the crude oil to the city of Calcutta; this was made of bamboo, but it is said that the loss by leakage was so great as to lead to its immediate abandonment on completion. In Russia, until 1875, the crude oil was carried in iron vessels, each of about 2000 gallons capacity, and when passed over the Kama river, was burnt by men standing on the bank, who were paid for the work by a fixed sum. These vessels were towed by two wheeled carts; the oil, from which the apparatus is obtained in the United States are drilled and cased in the same manner as the wells.

In the pipe-line system, the history of which dates from 1830. In that year S. D. Karns suggested laying a 6-in. pipe-line from the Tarr Farm wells to the refinery, which passed over a hill, the oil being moved on the syphon principle, and a year later was constructed another three miles long to the railway. These attempts were, however, unsuccessful, on account of the excessive leakage.
PETROLEUM

Crude petroleum was experimentally distilled in the United States in 1833 by Prof. Silliman (d. 1864), and the refining of petroleum in that country may be said to date from about the year 1855, when Samuel M. Kier fitted up a small refinery with a five-barrel still, and commenced the commercial refining of the oil obtained from his father's wells. At this period the supply of the raw material was insufficient to admit of any important development in the industry, and the output of the American wells for petroleum was initiated by Drake the "coal-oil" process for distillation of petroleum in considerable proportions in the United States. Two large refineries, one on Newton Creek, Long Island, and another in South Brooklyn, were in successful operation when the abundant production of petroleum, which immediately followed the completion of the Drake well, placed at the disposal of the refiner a material which could be worked more profitably than bituminous shale. In consequence refining operations were shortly begun in them for the refining of petroleum; but in the manufacture of burning oil from petroleum the small stills which had been in use in the distillation of shale-oil were at first employed.

In the earlier refineries, stills were used which varied from 25 to 80 barrels, usually consisted of a vertical cylinder, constructed of cast- or wrought-iron, with a boiler-plate bottom and a cast-iron dome, on which the "goose-neck" was bolted. The charge was distilled almost to dryness, through the operation was not carried far enough to cause the residue to "coke." The operation was, however, completely revolutionized in the United States by the introduction of the "cracking process," and the division of the distillation into two parts, one consisting in the removal of the more volatile constituents of the oil, and the other in the distillation (which is usually conducted in separate stills) of the residue from the first distillation, for the production of lubricating oils and paraffin.

Various arrangements have been proposed and patented for the continuous distillation of petroleum, in which crude oil is supplied to the stills at the rate of 20 to 30 barrels per day, largely employed in Russia, and its use has been frequently attempted in the United States, but the results have not been satisfactory, on account, it is said, of the much greater quantity of dissolved gas contained in the crude petroleum in the latter country than in that which such oil yields, and the less fluid character of the residue.

In the United States a horizontal cylindrical still is usually employed for the distillation of the "cracking process," but what is known as the "cheese-box" still has also been largely used. American stills of the former type are constructed of wrought-iron or steel, and are about 30 ft. in length by 12 ft. 6 in. in diameter, for distillation of oil, with 15 in. in diameter. The charge for such a still is about 600 barrels. The stills are formerly completely bricked in, so that the vapours should be kept fully heated until they escaped to the condenser, but since the introduction of the "cracking process," the upper part has usually been left exposed to the air. The cheese-box still has a vertical cylindrical body, which may be as much as 30 ft. in diameter, and 9 ft. in depth, connected by means of three vertical pipes with vapour lines, and carrying as many as forty, of 3-in. discharge-pipes arranged in parallel lines. The stills employed in Russia and Galicia are usually smaller than those here described.

The "cracking" process, whereby a considerable quantity of the oil which is intermediate between kerosene and lubricating oil is converted into hydrocarbons of lower specific gravity and more combustible vapor, is one of the most important scientific and technical interest. It is generally understood that the products of fractional distillation, even in the laboratory, are not identical with the hydrocarbons present in the crude oil, but are greatly reduced by the action of heat upon them. This was plainly stated by Professor Silliman in the earliest stages of development of the American petroleum industry. An important paper bearing on the subject was published in 1871, by T. E. Thorpe and C. N. H. Le Châtelier, in which they established a law, that, the higher the temperature, the more the hydrocarbons pass into the vapour state, or the lower the temperature, the more the hydrocarbons remain in the liquid state. They found that the paraffin was thus converted, with the evolution of but little light, into hydrocarbons which were liquid at ordinary temperatures. In an experiment, with a petroleum distillate of crude petroleum (melting point 45° C.) they obtained nearly 4 litres of liquid hydrocarbons, which they subjected to fractional distillation, and on analysis found that the fraction boiling in the neighborhood of 100°, they found it to consist mainly of olefins. The hydrocarbon C\textsubscript{7}H\textsubscript{12} might be resolved into C\textsubscript{6}H\textsubscript{10}+C\textsubscript{5}H\textsubscript{12} or C\textsubscript{6}H\textsubscript{10}+C\textsubscript{5}H\textsubscript{8}, &c., the general equation of the decomposition being

\[
C\textsubscript{7}H\textsubscript{14} \rightarrow C\textsubscript{6}H\textsubscript{10} + C\textsubscript{5}H\textsubscript{8} + 2H\textsubscript{2}
\]

or

\[
C\textsubscript{7}H\textsubscript{14} \rightarrow C\textsubscript{6}H\textsubscript{12} + C\textsubscript{5}H\textsubscript{8} + H\textsubscript{2}
\]

The product actually obtained is a mixture of several paraffins and olefins, however.

The cracking process practically consists in distilling the oils at a temperature higher than the normal boiling point of the constituents which it is desired to decompose. This may be brought about by a distillation under pressure, or by allowing the condensed distillate to fall into the highly heated residue in the still. The result of this treatment is that the comparatively heavy oils

at the joints of the pipes. With the adoption of carefully fitted screw-joints in 1865 the pipe line gradually came into general use, until in 1891 the lines owned by the various transit companies of Petroleum were 72 ft. in length.

The pumps employed to force the oil through the pipes were at first of the single-cylinder or "donkey" type, but these were found to cause excessive wear—at a defect remedied by the use of the double-cylinder type. The drilling of the large pipes for petroleum is done on the main 6-in. lines are of 600 to 800 h.p., while those on the small-diameter local lines range from 25 to 30 h.p.

Tanks of various types are employed in storing the oil, those at the refineries being made of well-seasoned white-oak staves bound by six or eight iron hoops. They are coated internally with glue, and painted in the well-known colours, blue staves and white heads. The tanks largely used for kerosene are made by machinery and contain 200, 300, 600, and 1000 barrel capacities. The cast-iron vessels are bored out, and their capacity is 35,000 barrels, and they are placed upon the carefully levelled ground without any foundation.

In Canada, means of transport similar to those already described are employed, but the reservoirs for storage often consist of excavations side or in the floor of the oil district, the sides of which are supported by piles.

The primitive methods originally in use in the Russian oil fields have already been described; but these were long ago superseded by a more efficient method of dealing with the crude petroleum. This consists in the introduction of the principle of supply by meter, and the adoption of a comprehensive system of reducing the initial pressure of the gas, so as to diminish loss by leakage. For the latter purpose, agencies have been set up in the different districts by which the positions of the regulators being so chosen as to equalize the pressure throughout the service. The gas is distributed to the consumer from the wells in wrought-iron pipes, ranging in diameter from 20 in. down to 2 in. Riveted wrought-iron pipes 3 ft. in diameter are also used. The initial pressure is sometimes as high as 400 lb. to the sq. in., but usually ranges from 200 to 300 lb. The actual demand of the cities is supplied by a series of pipes from 12 in. down to 2 in. in diameter, usually carrying a pressure of about 4 oz. to the sq. in. To these pipes the service-pipes leading into the houses of the consumers are connected.

Natural gas is largely used in the United States, and for some time, owing to defective methods of storage, delivery, and consumption, great waste occurred. The improvements introduced in the delivery of gas is that the pressure of the gas supplied through the distribution system was diminished by means of a meter in each house, and such a method of supply has led to a considerable economy in the consumption of gas. In 1846 applied to Prince Woronzoff for a subsidy for extending the use of petroleum-distillates in the Caucasus. In their application, which were very successful, they stated that they had taught the Don Cossacks "to burn natural gas," as a drawing, preserved in the archives of the Caucasian government, this how was achieved. They used an iron still, set in brickwork, and containing about 50 barrels of crude petroleum. They obtained a yield of sixteen buckets of "white naphtha." The top of the still had a removable head, connected with a condenser consisting of a copper worm in a barrel of water. The "white naphtha" which they obtained was used for illuminating purposes.

Some of the more viscous crude oils obtained in the United States are employed as lubricants under the name of "natural oils," either without any treatment or after clarification by subjection to a vaccum. The crude oils obtained in Kentucky and Ohio contain a large number, frequently, of a part of their more volatile constituents by spontaneous evaporation, or by distillation, in vacuo or otherwise, at the lowest possible temperature. Such are known as "reduced oils."
PETROLEUM

undergo dissociation, as shown by the experiments of Thorpe and Young, by forming higher hydrocarbons of lower boiling points, and the yield of kerosene from ordinary crude petroleum may thus be greatly increased. A large number of arrangements for carrying out the cracking process have been proposed and patented, probably the best known being that of J. L. Fahy, and that of R. W. Young, who in 1865 patented his "Improvements in treating hydrocarbon oils." In this patent, the distillation is described as being conducted in a vessel having a loaded valve or a piston to close the vessel, and the vapour is evolved under any desired pressure. Under such conditions, distillation takes place at higher temperatures than the normal boiling-points of the constituent hydrocarbons of the oil, and a portion of the water and air, carbon dioxide or other gas, under the required pressure, and the condenser being provided with a regulated outlet for condensed liquid. An objectionable feature of the system of allowing the vapour to escape from the still to the condenser through a loaded valve, viz. the irregularity of the distillation, is thus removed, and the benefits of regular vaporization and condensation under high pressure are obtained. In the American petroleum refining it is found that sufficient cracking can be produced by slow distillation in stills of which the upper part is sufficiently cool to allow of the condensation of the vapours of the less volatile hydrocarbons, and the condensed liquid thus falling back into the heated body of oil.

In the earlier stages of the development of the manufacture of mineral lubricating oils, the residues were distilled in cast-iron stills, and the vaporizing properties of the products thus obtained were injured by overheating. The modern practice is to employ horizontal cylindrical wrought-iron or steel stills, and to introduce steam into the oil. The steam is superheated and may thus be heated to a much higher temperature than the original oil, without the risk of overheating, and this considerably shortened the time which would be liable to damage the still. The steam operates by carrying the vapors away to the condenser as fast as they are generated, the injury to the products resulting from their remaining in contact with the highly-heated surface of the still being thus prevented.

In order to separate the distillate into various fractions, and to remove as much of it as possible free from the products of decomposition and asphalt, which are injurious to the products of condensation, and to the quality of the products, it is now usual to employ condensing apparatus of special form with outlets for running off the different fractions.

The process of distillation of lubricating oils under reduced atmospheric pressure is now in very general use, especially in obtaining the heavier products. The vapours from the still pass through a condenser into a receiver, which is in communication with the exhauster.

The products obtained by the distillation of petroleum are not in a marketable condition, but require chemical treatment to remove acid and other bodies which impart a dark colour as well as an unpleasant odour to the liquid, and in the case of lamp-oils, oils, and tallow, an unpleasant taste. A still further treatment of decolourization is necessary.

At the inception of the industry kerosene came into the market as a dark yellow or reddish-coloured liquid, and in the first instance, the oil was exposed to all the atmospheric heat of the sun before the tallow and clay solution. It was, however, found that after the oil so purified had been burned in a lamp, for a short time, the wick became encrusted, and the oil failed to rise properly. Eichler, of Baku, is sarsonic a source of the first motor fuel in order to the use of sulphuric acid, followed by that of soda lye, and his process is in universal use at the present time. The rationale of this separation is not fully understood, but the action appears to consist in the separation of decomposition or combination of the aromatic hydrocarbons into a base of recognized standards of quality, and testing is necessary in the interests of both refiner and consumer, as well as compulsory in connexion with the various statutory and municipal regulations.

The determination of the specific gravity is a basis of recognized standards of quality, and testing is necessary in the interests of both refiner and consumer, as well as compulsory in connexion with the various statutory and municipal regulations. In the testing of the viscosity of lubricating oils the Boventor Redwood standardized viscometer is generally employed in Great Britain. It is one of the Saragino Elsine type, and the vapour of a measured quantity of the oil through a small orifice at a given temperature is measured.

Uses.—Petroleum has long been known as a source of light and heat, while the use of crude oil for the treatment of wounds and cutaneous affections, and as a lubricant, was even more general and led to the raw material being an article of commerce at a still earlier date. For pharmaceutical purposes crude petroleum is no longer generally used by civilised races, though the product vaseline is largely employed in this way, and emulsions of petroleum have been administered internally in various pectoral complaints; while the volatile product termed rhigolene has been largely used as a local anaesthetic.

For illuminating purposes, the most extensively-used product is kerosene, but both the more and the less volatile portions of petroleum are employed in suitable lamps. Petrol lamps are largely utilized for (1) the production of "air-gas," (2) the manufacture of oil-gas, and (3) the enrichment of coal-gas. For heating purposes, the stoves employed are practically kerosene lamps of suitable construction, though gasoline is used as a domestic fuel in the United States.

The use of petroleum as liquid fuel is dealt with under FUEL, as is the employment of its products in motors, which has greatly
PETROLOGY

increased the demand for petroleum spirit. Petroleum has largely superseded other oils, and is still gaining ground, as a lubricant for machinery and railway rolling-stock, either alone or in admixture with fixed oils. The more viscous descriptions of mineral oils have also been found suitable for use in the Elmore process of ore-concentration by oil.

Legislation.—Since the inception of the petroleum industry, most civilized countries have prescribed by law a test of flash-point or inflamability in mineral oil, primarily to afford a definition of oils for lighting purposes which may be safely stored without the adoption of special precautions. In the United Kingdom the limit fixed for the purpose in question, been fixed by the legislature at 73° F., which is equivalent of the former standard of 100° F. by the "open-test." While the subject of the testing of petroleum for legislative purposes has been considered by both British and American committees of both branches of the legislature, with a view to change the law, the standard has never been raised, since such a course would tend to reduce the available supply and thus lead to increase in price or deterioration in quality. Moreover the chief object of the Petroleum Acts passed in the United Kingdom has hitherto been to regulate and control it, it has always been possible to obtain oils either of higher or lower flash-point, when such are preferred, irrespective of the legal standard, in which it may be asserted that in a properly constructed lamp used with reasonable care the ordinary oil of commerce is a safe illuminant. The more recent legislation with regard to "petroleum spirit" relates mainly to the quantity which may be handled in the open air, and to the light limits. The more important local authorities throughout the county have made regulations under the powers conferred upon them by the Petrolum Oil Act 1876 for regulating the "keeping a sale, conveyance and hawking" of petroleum products having a flash-point below 73° F., and the Port of London Authority, together with other water-way and harbour authorities in the United Kingdom, have their own by-laws relating to the navigation of vessels carrying such petroleum.

In other countries the flash-point standards differ considerably, as do the storage regulations. In France, the standard is 35° C. (Granier tester, equivalent to 90° F.), and according to their law, liquid hydrocarbons are divided into two classes (below and above 35° C.), considered differently in regard to quantities storable and other regulations. In Germany, the law prescribes a close-test flash-point of 73° F., and in Russia this is fixed at 28° C., equal to 82.4° F., by the close-test; in both these countries the weights of petroleum which may be stored in specified buildings are determined by law. In the United States, various methods of testing and various minimum standards have been decreed. In Pennsylvania, the prescribed limit is a "fire-test" of 110° F., equivalent to about 70° F., close-test, while in the State of New York it is 100° F. close-test.

PETROLOGY: the science of rocks (Gr. πέτρα), the branch of geology which is concerned with the investigation of the composition, structure, history, origin, and classification of rocks, and which make up the accessible portions of the earth's crust. Rocks have been defined as "aggregates of minerals." They are the units with which the geologist deals in investigating the structure of a district. Some varieties cover enormous areas and are among the commonest and most familiar objects of nature. Granite, sandstone, clay, limestone, slate often form whole provinces and build up lofty mountains. Such unconsolidated materials as sand, gravel, clay, soil are justly included among rocks as being mineral masses which play an important rôle in field geology. Other rock species are of rare occurrence and may be known in only one or two localities in distant parts of the earth's surface. Nearly all rocks consist of minerals, whether in a crystalline or non-crystalline state, and the impenetrable parts of the skeletons of animals and plants may constitute a considerable portion of rocks, as for example, coral limestone, lignite beds and chalk.

Treatment of the Subject.—In this paragraph the subject matter of the science of petrology is briefly surveyed; the object is to point out the headings under which particular subjects are treated (these being separate articles on the terms printed in italics). General questions as to the origin and classification of rocks, and of methods of examination are discussed in the present article; mineralogy comprises similar matter respecting the component minerals; metamorphism, metasomatism, pneumatolysis and the formation of concretions are agencies which effect rocks and modify them. Three classes of rocks are recognized: the igneous, sedimentary and metamorphic. The plutonic or, deep-seated rocks, which cooled far below the surface, and occur as batholiths, lenses, laccoliths, dikes, sills, etc., are included as the "igneous" class, and porphyries, gabbros, etc., are the "intrusive" varieties; related to the granites are the olivine, gneiss, pegmatite, schist rock and micropegmatite; to the syenites, boronite, monzonite, pegmatite, leucitophyre and dikes, lapphite, nepheline, apatite, tourmaline and tonalite; to the gabbros, pyroxenite and pyroxene, etc., are the "extrusive" or "volcanic" rocks, to porphyrites, picrite and serpentine. The hypabyssal intrusive rocks, occurring as sills, vein, dikes, etc., are represented by porphyries, hornblende, plagioclase, etc., (feldspar, a carbonate phry, diabase and lamprophyre; some pitchstones belong to this group and contain crystalsulphides and sphalerites. The volcanic rocks, found typically as lava flows, include rhyolite and obsidian (with chalcedony), porphyry, scoria, obsidian and andesite. The latter is treated under leucite, andesite and dacite, basalt (with the related dolerite, variscite and trachyte), nepheline and lephtite. Among these the commonest are the rhyolite, andesite and basalt, the latter being the most important.

Composition.—Only the commonest minerals are of importance as rock formers. Their number is small, not exceeding a hundred in all, and much less than this if we do not reckon the subdivisions into which the commoner species are broken up. The vast majority of the rocks which we see around us every day consist of quartz, felspar, mica, chlorite, kaolin, calcite, epidote, olivine, augite, hornblende, magnetite, haematite, limonite and a few other minerals. Each of these has a recognized position in the economy of nature. A main determining factor is the chemical composition of the mass, for a certain mineral can be formed only when the necessary elements are present in the rock. Calcite is commonest in limestones, as these consist essentially of carbonates; quartz in sandstones and in certain igneous rocks which contain a high percentage of silica. Other factors are of equal importance in determining the natural association or paragenesis of rock-making minerals, principally the mode of origin of the rock and the stages through which it has passed in attaining its present condition. Two rock masses may have very much the same bulk composition and yet consist of entirely different assemblages of minerals. The tendency is always for those compounds to be formed which are stable under the conditions under which the rock mass originated. A granite arises by the consolidation of a molten magma (a fused rock mass; Gr. "μελαν," from μαλακιον, to knead) at high temperatures sometimes 1000° C. and above, and its component minerals are such as are formed in such circumstances. Exposure to moisture, carbonic acid and other subaerial agents at the ordinary temperatures of the earth's surface, some of these original minerals, such as quartz and white mica are permanent and remain unaffected; others "weather" or decay and are replaced by new combinations. The felspar passes into kaolin, muscovite and quartz, and if any black mica (biotite) has been present it yields chlorite, epidote, rutile and other substances. These changes are accompanied by disintegration, and the rock falls into a loose, incoherent, earthy mass which may be regarded as a sand or soil. The materials thus formed may be washed away and deposited as a sandstone or gravel. The structure of the original rock is never replaced by a new one; the mineralogical constitution is profoundly altered; but the bulk chemical composition may be very different. The sedimentary rock may again undergo a metamorphism. If penetrated by igneous rocks it may become recrystallized or, if subjected to enormous pressures with heat and movement, such as when the building of folded mountain chains, it may be converted into a gneiss not very different in mineralogical composition though radically different in structure to the granite which was its original state.

Structure.—The two factors above enumerated, namely the chemical and mineral composition of rocks, are scarcely of greater
importance than their structure, or the relations of the parts of which they consist to one another. Regarded from this standpoint rocks may be divided into the crystalline and the fragmental. Inorganic matter, if free to take that physical state in which it is most stable, always tends to crystallize. Crystalline rock masses have consolidated from solution or from fusion. The vast majority of igneous rocks belong to this group and the degree of perfection in which they have attained the crystalline state depends primarily on the conditions under which they solidified. Such rocks as granite, which have cooled very slowly and under great pressures, have completely crystallized, but many lavas were poured out at the surface and cooled very rapidly; in this latter group a small amount of non-crystalline or glassy matter is frequent. Other crystalline rocks such as rock-salt, gypsum and anhydrite have been deposited from solution in water, mostly owing to evaporation on exposure to the air. Still another group, which includes the marbles, mica-schists and quartzites, are recrystallized, that is to say, they were at first fragmental rocks, like limestone, clay and sandstone and have never been in a molten condition nor entirely in solution. Certain agencies however, acting on them, have effaced their primitive structures, and induced crystallization. This is a kind of metamorphism.

The fragmental structure needs little explanation; wherever rocks disintegrate fragments are produced which are suitable for the formation of new rocks of this group. The original materials may be organic (shells, corals, plants) or vitreous (volcanic glasses) or crystalline (granite, marble, &c.); the pulverizing agent may be frost, rain, running water, or the steam explosions which shatter the lava within a volcanic crater and produce the fragmental rocks known as volcanic ash, tuffs and agglomerates. The materials may be loose and incoherent (sand, clay, gravel) or compacted by pressure and the deposit of cementing substances by percolating water (sandstone, shale, conglomerate). The grains of which fragmental rocks are composed may be coarse or fine, fresh or decayed, uniform or diverse in their composition; the one feature which gives unity to the class is the fact that they are all derived from pre-existing rocks or organisms. Because they are made up of broken pieces these rocks are often said to be "clastic."

Origin of Rocks.—The study of the structure of rocks evidently leads us to another method of regarding them, which is more fundamental than those enumerated above, as the structure depends on the mode of origin. Rocks are divided into three great classes, the igneous, the Sedimentary and the Metamorphic.

Igneous Rocks. The igneous (Lat. ignis, fire) rocks have all consolidated from a state of fusion. Some of them are crystalline or "massive"; others are fragmental. The fragmental igneous rocks include a few which are nearly completely vitreous, and all more which contain a small amount of amorphous matter, but the majority are completely crystallized. Among the best known examples are obsidian, pumice, basalt, trachyte, granite, diorite. The fragmental igneous rocks consist of volcanic ashes more or less firmly compacted.

Sedimentary Rocks. The sediments forms a second group; they have all been laid down as deposits on the earth's surface subject to the conditions of temperature, moisture and pressure which obtain there. They include fragmental and crystalline varieties. The former consist of the débris of pre-existing rocks, accumulated in seas, lakes or dry land and more or less indurated by pressure and cementing substances. Sand and gravel, sand and clay, conglomerate, sandstone, shale are well-known examples. Many of them are fossiliferous as they contain fragments of organisms. Some are very largely made up of remains of animals or plants, more or less altered by mineralization. These are sometimes placed into a special group as rocks of organic origin; limestone, peat and coal are typical of this class. The crystalline sediments are such as rock-salt and gypsum, deposits of saline lakes or isolated portions of the sea. They were formed under conditions unfavourable to life and hence rarely contain fossils. The metamorphic rocks are known to be almost entirely altered igneous or sedimentary masses. Metamorphism consists in the destruction of the original structures and the development of new minerals. The chemical composition of the rocks however suffers little change. The rock becomes as a rule more crystalline; but all stages in the process may be found and in a metamorphosed sediment, e.g. a sandstone, remains of the original sand grains and primary fragmental structure may be observed, although extensive recrystallization has taken place. The agencies which produce metamorphism are high temperatures, pressure, interstitial moisture and in many cases movement. The effects of high temperatures are seen best in the rocks surrounding great outcrops of intrusive granite, for they have been baked and crystallized by the heat of the igneous rock (thermo-metamorphism). In folded mountain chains where the strata have been greatly compressed and their particles have been forced to move over one another a different type of metamorphism prevails (regional or dynamic metamorphism).

Methods of Investigation.—The macroscopic (Gr. μακρός, large) characters of rocks, those visible in hand-specimens without the aid of the microscope, are very varied and difficult to describe accurately and fully. The geologist in the field depends principally on them and on a few rough chemical and physical tests; and to the practical engineer, architect and quarry-master they are all-important. Although frequently insufficient in themselves to determine the true nature of a rock, they usually serve for a preliminary classification and often give all the information which is really needed. With a small bottle of acid to test for carbonate of lime, a knife to ascertain the hardness of rocks and minerals, and a pocket lens to magnify their structure, the field geologist is rarely at a loss to what group a rock belongs. The fine grained species are often indeterminable in this way, and the minute mineral components of all rocks can usually be ascertained only by microscopic examination. But it is easy to see that a sandstone or grit consists of more or less rounded, waterworn sand-grains and if it contains dull, weathered particles of felspar, shining scales of mica or small crystals of calcite these also rarely escape observation. Shales and clay rocks generally are soft, fine grained, often laminated and not infrequently contain minute organisms or fragments of plants. Limestones are easily marked with a knife-blade, effervesce readily with weak cold acid and often contain entire or broken shells or other fossils. The crystalline nature of a granite or basalt is obvious at a glance, and while the former contains white or pink felspar, clear vitreous quartz and glancing flakes of mica, the other will show yellow-green olivine, black augite and grey striated plagioclase.

But when dealing with unfamiliar types or with rocks so fine grained that their component minerals cannot be determined with the aid of a lens, the geologist is obliged to have recourse to more delicate and searching methods of investigation. With the aid of the blowpipe (to test the fusibility of detached crystals), the goniometer, the magnet, the magnifying glass and the specific gravity balance, the earlier travellers attained surprisingly accurate results. Examples of these may be found in the works of von Buch, Scrope, Darwin and many others. About the end of the 18th century, Dolomieu examined crushed rock powders under the microscope and Cordier in 1815 crushed, levigated and investigated the finer ground-mass of igneous rocks. His researches showed for the first time that different species of rocks are distinguished not only by the minerals of which they consist but also by that they consisted essentially of such minerals as felspar, augite, iron ores and volcanic glass, and did not differ in nature from the coarser grained rocks. Nicol, whose name is associated with the discovery of the Nicol's prism, seems to have been the first to prepare thin slices of mineral substances, and his methods were applied by Witham (1831) to the study of plant petrifications. This method, of such far-reaching importance in petrology, was not at once made use of for the systematic
investigation of rocks, and it was not till 1858 that Sorby pointed out its value. Meanwhile the optical study of sections of crystals had been advanced by Sir David Brewster and other physicists and mineralogists and it only remained to apply their methods to the study of rocks. Some progress was made and the names of Zirkel, Allport, Vogelsang, Schuster, Rosenbusch, Bertrand, Fouqué and Lévy are among those of the most active pioneers in the new field of research.

To such importance have microscopical methods attained that textbooks of petrology at the present time are very largely devoted to a description of the appearances presented by the minerals of rocks as studied in transparent micro-sections.

A good rock-section should be about one-thousandth of an inch in thickness; the section of the rock should be cut off near the middle of the rock (or, better still, near the edge of the rock) for the purposes of examination. A thin splinter of the rock, about as large as a halfpenny may be taken; it should be as fresh as possible and free from obvious cracks. By grinding on a plate of planed steel or cast iron with sand paper, or emery paper, and then cleaning with alcohol, dirt may be avoided by cutting off a smooth slice with an iron disk armed with crushed diamond powder. A second application of the slitter after the first face is smoothed and cemented to the glass will in expert hands leave a rock-section so thin as to be already transparent.

In this way the preparation of a section may require only twenty minutes.

A microscope employed is usually one which is provided with a rotating stage beneath which there is a polarizer, while above the objective or the eye-piece an analyser is mounted; alternatively the stage may be fixed and the polarizing and analysing prisms interposed between the stage and the object-glass. A rotating stage is advantageous because if the slide is made of toothed wheels and a connecting-rod. If ordinary light and not polarized light is desired, both prisms may be withdrawn from the axis of the instrument; if the polarizer only is inserted the light transmitted is plane polarized; with both prisms in position the slide is viewed between "crossed nics." A microscopic rock-section in ordinary light if a suitable magnification (say 30) is employed is seen to consist of grains or crystals varying in colour, size, form and optical properties. Some minerals have a peculiar colour reaction, which, if present, may be used to identify them. The presence of iron oxides may be detected by heating the slide, when the oxide layer may be easily scraped away. The iron oxide will then be black when it is heated in reducing atmosphere and orange when it is heated in a non-reducing atmosphere. The degree of oxidation of the iron oxide is often very striking. This property, known as "pleochroism" (Gr. πλεόχρωμα, more; χρῶμα, colour), is of great value in the determination of minerals. Among minerals there are none which surround minute enclosures of other minerals, such as zircon and epidote; these are known as "pleochroic halos."

It is a power that may be added to a rock-section for the purpose of separating the minerals which compose it; it is obtained by rotating the stage till the plane parallel to the section of the rock is at right angles to the polarizing Nicol, when the mineral is rendered transparent. The only exception to this rule is provided by sections which are perpendicular to the optic axes of birefringent crystals; these remain dark or nearly dark during whole rotation, and as will be seen later, their investigation is of special importance. The doubly refracting mineral sections, however, will in all cases appear black in certain positions as the stage is rotated, and their character will be apparent in this position. The use of the polarizer enables the analyst to decide which of the minerals present are doubly refracting.

The mineral sections when not extinguished are not only bright but are coloured and the colours they show depend on several factors, the most important of which is the strength of the double refraction. When the sections are relatively thin and the mineral is well cut, the slides, the minerals with strongest double refraction yield the highest polarization colours. The order in which the colours are arranged is that known as Newton's scale, the lowest being yellow, orange, red, violet, indigo, blue, in that order, and the highest being green, blue, indigo, violet, red, orange, yellow, so on.

The difference between the refractive indices of the ordinary and extraordinary ray in quartz is -009, and in a rock-section about 009 of an inch thick this mineral gives grey and white polarisation tints; nepheline with weaker double refraction gives dark grey; augite on the other hand will give red and blue, while calcite with still stronger double refraction will appear pinkish or greenish white. All sections of the same mineral, however, will not show the same tint. Sometimes the colour derived from an optic axis will be seen to show a line parallel to it; this line is then called the extinction line. Usually the extinction line will be the production of the optic axis, which is nearly parallel to an optic axis will be nearly black, and, in general, the more nearly any section approaches this direction the lower its polarization colours. The closer the section is to the optic axis, the stronger the common to any given by any mineral, the relative value of its double refraction can be estimated; or if the thickness of the section be precisely known the difference between the two refractive indices can be ascertained. If the slides be thick the colours will be on the whole higher than in thin slides.

It is often important to find whether of the two axes of elasticity (or vibration traces) in the section is that of greater elasticity or less (the refractive index). The quartz wedge or selenite plate enables us to do this. Suppose a doubly refracting mineral section so placed that it is "extinguished"; if now it is rotated through 45° it will be brightly illuminated. If the quartz wedge be passed between the mineral section and the polarizing Nicol a quarter of a turn of the stage will cause the section to approach the extinction position; this is the position of the section proper. If it is lowered half a turn, the section is then parallel to the Nicol and the section is then in the position of "half extinction." If the mineral section is not in this position of half extinction, the section is not in its true position of extinction. The determination of the double refraction of the section is therefore of great value in the determination of the section because it is obviously equal and opposite to that of a known part of the quartz wedge.

A further refinement of microscopic methods consists of the use of a Bunsen wedge. A Bunsen wedge is a piece of optically transparent glass coating a wedge, the angle of which is obtained by a wide angled achromatic condenser above the polarizer, and a high power microscopic object case. Those sections are most useful which are perpendicular to an optic axis, and consequently when the slide is turned the part of the slide parallel to the optic axis will be the most brightly illuminated. If the slide has a section through uniaxial mineral crystals, they show a dark cross or convergent light between crossed nics,
Petrology

The bars of which remain parallel to the wires in the field of the eyepiece. Sections perpendicular to the wires show a black bar which on rotation becomes curved to a hyperbolic shape. If the section is perpendicular to a "bisectrix" (see Crystallography) a black cross is seen which on rotation opens out to form two hyperbolas, the apices of which are turned towards one another. The optic axes emerge at the apices of the hyperbolas and may be surrounded by coloured rings, owing to the thinness of minerals in rock sections through the double refraction of the resin. The distance between the axes as seen in the field of the microscope depends partly on the axial angle of the crystal and partly on the numerical aperture of the objective. If it is intended for the examination of ferromagnesian minerals the axial angle of the mineral can be found by a simple calculation. The quartz wedge, quarter-mica plate or selenite plate permit the determination of the positive or negative character of the crystal and the bisectrix of the crystal can be separated if the differences observed in the field. Those operations are precisely similar to those employed by the mineralogist in the examination of plates cut from crystals. It is sufficient to point out that the petrological microscope in its modern development is an optical instrument of great precision, enabling us to determine physical constants of crystallized substances as well as serving to produce magnified images like the ordinary microscope. A great variety of accessory apparatus has been devised to fit it for these special uses.

The separation of the ingredients of a crushed rock powder from one to another in order to obtain pure samples suitable for analysis is also extensively practised. It may be effected by means of a powerful electro-magnet. The strength of which can be regulated as desired. A weak magnetic field will attract magnetite, then haematite, and other ores of iron. Silicates containing iron will follow in definition, pyroxene and biotite, enstatite, augite, hornblende, garnet and similar ferro-magnesian minerals may be successively abstracted; at last only the colourless, non-magnetic compounds, such as muscovite, calcite, quartz and felspar, will remain. Chemical methods also are useful. A weak acid will dissolve calcite from a crushed limestone, leaving only dolomite, silicates or quartz. Hydrofluoric acid will attack felspar before quartz, and if employed with great caution will dissolve these and any glassy material in a rock powder before dissolving augite or hypersthene. Methods of separation by specific gravity have a still wider application. The simplest of these is levigation (Lat. lentgere, to make smooth, leat) or treatment by a current of water; it is extensively employed in the mechanical analysis of soils and in the treatment of ores, but is not so successful with rocks, as their components do not as a rule differ very greatly in specific gravity.

Fluids are used which do not attack the majority of the rock-making minerals and at the same time have a high specific gravity. Solutions of potassium mercuric iodide (sp. gr. 3-196), calcium benzoate (sp. gr. 1-7), methylene iodide (sp. gr. 2-80), or acrylence bromide (sp. gr. 3-00) are the principal media employed. They may be diluted (with water, benzene, &c.) to any desired extent and again concentrated by evaporation. If the rock be a granite consisting of biotite (sp. gr. 3-11), muscovite (sp. gr. 2-85), quartz (sp. gr. 2-65), oligoclase (sp. gr. 2-64) and orthoclase (sp. gr. 2-56) the crushed minerals will float in methylene iodide; on gradual dilution with benzene they will be precipitated in the order given above. Although simple in theory these methods are tedious in practice, especially as it is common for one rock-making mineral to enclose another. But expert hands can isolate rock-making minerals and the purest powders may be obtained by this means than by any other.

Although rocks are now studied principally in microscopic sections the investigation of fine crushed rock powders which was the first branch of microscopic petrology to receive attention, is by no means discontinued. Powders. The modern optical methods are perfectly applicable to transparent mineral fragments of any kind. Minerals are identified in the powdered rock as in section; but it is otherwise with rocks, as the structure or relations of the mineral components to one another, which is an element of great importance in the study of the history and classification of rocks, is almost completely destroyed by grinding them to powder.

In addition to naked-eye and microscopic investigations chemical methods of research are of the greatest practical utility to the petrographer. The crushed and separated powders, obtained by the processes described above, may be analysed and thus the chemical composition of the minerals in the rock determined qualitatively or quantitatively. The chemical testing of microscopic sections and minute grains by the help of a microscope is a valuable and valuable means of discriminating between the mineral components of fine-grained rocks. Thus the presence of apatite in rock-sections is established by covering a bare rock-section with solution of ammonium molybdate; a turbid yellow precipitate forms over the crystals of the mineral in question (indicating the presence of phosphates). Many silicates are insoluble in acids and cannot be tested in this way, but others are partly dissolved, leaving a film of gelatinous silica which can be stained with colouring matters such as the aniline dyes (nepheline, analcalite, zeolites, &c.).

Complete chemical analyses of rocks are also widely made use of and are of the formation of orthoclase, quartz and mica (the minerals of granite). Sir James Hall also made the first contribution to the experimental study of metamorphic rocks by converting chalk
The rock consists of alternate bands of brown and colourless glass which have been arranged in stripes by the fluxion movement of the viscous mass before solidification. The glass is rendered granular by very minute crystals.

In the centre are crystals of felspar, rather turbid through weathering. The matrix is partly glassy, partly felsitic, and shows the effects of streaming movements with eddies behind the felspar crystals.

This rock has a damascened pattern owing to the irregular mingling of streams of brown and of colourless glass. It is nearly quite free from minute crystals.

The clear glassy rock is traversed by a large number of cracks, some long and straight, while others are nearly circular. These are rendered more distinct by the deposit of thin films of secondary limonite in them. The cracks are due to contraction on cooling.

In the clear glassy base there are rounded yellow spots (spherulites) arranged in fluxion streams.

The round spherulites of this rock are large and sometimes composite; their radiate structure is obvious. This is a devitrified pitchstone, no longer glassy but finely crystalline, and at the centres of the spherulites there are spaces occupied by a secondary deposit of quartz.

The ground-mass is partly glassy, partly felsitic, and shows fluxion-banding. The large quartz is a double hexagonal pyramid, but its edges and corners are rounded by corrosion and large irregular areas of glass penetrate to its centre.
PETROLOGY

A large porphyritic felspar crystal is seen lying in a pale-brown, glassy base and containing many glass inclusions of irregular shape. The felspar, in one margin especially, shows corroded outlines.

In this rock there are porphyritic crystals of felspar and of dark brown biotite (nearly black in the photograph), with a few of green augite and magnetite. The ground-mass is finely crystalline.

This is a non-porphyritic, holocrystalline rock. Among its components the crystals of dark mica are conspicuous, and with them occur also a few plates of white mica, with perfect cleavage. The slightly turbid or granular substance is felspar, a little decomposed, and the large clear spaces are crystals of quartz.

This rock consists of angular patches of clear quartz scattered through a striated dull matrix of felspar. The different quartz areas have all the same optical orientation, as if they were parts of a single crystal.

In this variety of tourmaline-granite there are many blue needles of tourmaline, grouped in stellate clusters which are embedded in a matrix of clear quartz. These pointed needles diverge from the surfaces of larger grains of tourmaline.

The dark crystals are green hornblendes, and show the outlines which are characteristic of that mineral. The cloudy grey substance between them is felspar in a somewhat weathered state.

into marble by heating it in a closed paper-barrel, which prevented the escape of the carbon dioxide at high temperatures. Adams and Nicholson have carried this a stage farther by subjecting marble to great pressure in hydraulic presses and have shown how the foliated structures, frequent in natural marbles, may be produced artificially.

Rock Classification.—The three great classes of rocks above enumerated—the igneous, the sedimentary and the metamorphic—are subdivided into many groups which to a small extent resemble the genera and species under which the naturalist classifies the members of the animal kingdom. There are, however, no hard and fast boundaries between allied rocks. By increase or diminution in the proportions of their constituent minerals they pass by every gradation into one another; the distinctive attributes of one kind of rock gradually pass into those of another. Hence the definitions adopted in establishing rock nomenclature merely correspond to selected points (more or less arbitrary) in a continuously graduated series. This is frequently urged as a reason for reducing rock classification to its simplest possible terms, and using only a few generalized rock designations. But it is clear that many apparently trivial differences tend regularly to recur, and have a real significance, and so long as any variation can be shown to be of this nature it deserves recognition.

The igneous rocks (crystalline and fragmental) form a well-defined group, differentiating all other rocks by the presence of crystals. Varieties may occur in two different ways: the lavas have been poured out at the surface and have consolidated after eruption (basalt, etc.), or they have been crystallized by cooling in any part of the world; the intrusive rocks, on the other hand, have been injected from below into cracks and fissures in the strata and have cooled there (granite, etc.). The intrusive rocks (or dikes) are completely solidified in the rocks in contact with them. But as their heat could dissipate only very slowly, because of the masses which covered them, complete crystallization has taken place and no vitreous masses or clay-like masses are present. They cannot come to rest before crystallizing; they are not fluidal. Their contained gases have not been able to escape through the thick layer of strata beneath which they were injected, and may often be observed occupying cavities in the minerals. It has been shown that at times when most of the rock was still liquid and are more or less perfect; the later are less regular in shape because they were compelled to occupy the interstices left between the already formed crystals (Pl. II, figs. 9). The former are said to be idiomorphic (or automorphic), the latter are anidiomorphic (alloidomorphic, xenomorphic). There are also many other characteristics which serve to distinguish them and to separate them into various subgroups. For example, the typical felspar of granite, while its modification sanidine occurs in lavas of similar composition. The same distinction holds between elaeoclast and nepheline. Leucite is common in lavas, very rare in hypabyssal. Many of the characteristics which we have enumerated above tend to be more pronounced as the rate of cooling increases, and the differences show the influence of the physical conditions under which consolidation takes place.

There is a certain class of intrusive rocks which have risen upward towards the surface and have failed to reach it, and have solidified in fissures as dikes and intrusive sills at no great depth. To this type the name intrusive (or hypabyssal) is often given in distinction to the plutonic (or bathyal) types, which formed at greater depths. As might be expected, they show structures intermediate between those of the effusive and the plutonic rocks. They are very commonly porphyritic; that is, they contain large crystals or phenocrysts which are independent of the matrix and which may be indistinguishable petrologically from lavas of similar composition.

The attempt to form a special group of hypabyssal (intrusive or dike) rocks has met with little success, because it is clear that this group cannot rank as equally important and equally well characterized with the plutonic and the effusive. But there are many kinds of rock which are not found to occur normally in any other manner. As examples we may cite the lamprophyres, the andesites and the porphyrites. These never occur as lava flows or as great plutonic masses; if magmas of the same composition as these rocks occur in either of these ways they consolidate with distinct alteration of mineral composition in combination of the hypabyssal and the plutonic rocks. This

Subdivisions of Igneous Rocks.

Igneous Rocks

Igneous Rocks

...
The commoner rock constituents are nearly all oxides: chlorine, sulfur, and iron are present, but in small quantities, and their total amount in any rock is usually much less than 1%.

Clarke, F. W., has calculated that a little more than 47% of the earth's crust consists of oxygen. It occurs predominantly in combination with calcium, silicon, and other elements which are silica, alumina, iron oxides, lime, magnesia, potash and soda.

The silica functions principally as an acid, forming silicates, and all the commoner minerals of igneous rocks are of this nature. From this source, rocks containing 65 to 75% of silica are known as granite, which we have already met with in the crystalline rocks of the world's crust today, and the remainder of which is free from other silicates are known as dolerite. These two types of rock are characterized by the abundance of their respective minerals, namely, quartz and felspar.

The magnesium and iron oxides are abundant, and the general character of the rocks is determined by the amount and kind of these materials and their distribution. A very simple first division of rocks based on this consideration is the classification into basic, intermediate, and felspathal varieties.

In which felspathal minerals occur, and indeed there are many transitions between syenites of ordinary type and nephelite—leucite, and these latter with gabbro or dolerite or tephrite or essexite. But as many minerals develop in these "alkali" rocks which are generally known as "alkali rocks", it is convenient in a purely formal classification like that which is outlined here to treat the whole series as a distinct class.

**Nepheline and Leucite-bearing Rocks.**

This classification is based essentially on the mineralogical constitution of the igneous rocks. Any chemical distinctions between the different groups, though implied, are relegated to a subordinate position. It is admittedly artificial but it has grown up with the growth of the science and is still adopted as the basis on which more minute subdivisions are erected. The subdivisions are by no means of equal value. The syenites, for example, and the peridotites, are of less importance than the granites, diorites and gabbros. Moreover, the effusive andesites do not always correspond to the plagioclase diorites but partly also to the gabbros. As the different kinds of rock, regarded as aggregates of minerals, pass gradually into one another, it is convenient to regard them as if they were all of the same kind and to regard them as if they were all of the same kind.

The rocks which contain leucite or nepheline, either partly or wholly, are classified as nepheline-eosynites, and are essentially of intermediate or of basaltic character. They might in consequence regard them as varieties of syenite, diorite, gabbro, &c., and there is a corresponding series of basic rocks. Lastly a small sub-group rich in olivine and without felspar has been called the "ultrabasic" rocks. They have very low percentages of silica but much iron and magnesia.

Except these last practically all rocks contain felspars or felspathal minerals. The acid rocks the common felspar is orthoclase, with perthite, microcline, oligoclase, all having much silica and alkalis. In the basic rocks labradorite, anorthite and bytownite prevail, being rich in lime and poor in silica, potash and soda. As a rule the common felspathal minerals of both the basic rocks, but biotite and hornblende are on the whole more frequent in the acid.

to be unique, turn up with ideental features in widely scattered regions, ándíté, for example, occurs in Norway, Scotland, Montreal, British Columbia, and Arkansas. It may be due to local differentiation processes in the magma, such as those in Norway, Brazil, Montana, Portugal, &c. This indicates that underlying all the variations in mineralogical, structural, and chemical properties there are definite relationships which tend to repeat themselves in different localities, and our present understanding of the same conditions is present.

Although in former years the view was widely current, especially in Germany, that the various rocks belonging to different geological systems should receive different names, it is now admitted on all sides that this cannot be upheld.

In 1902 a group of American petrographers brought forward a system of classification of some petrological groups, and to substitute for them a "quantitative" classification based on chemical analysis. They showed how vague and often unscientific was much of the existing terminology and argued that as there is in crystallography of an igneous rock, a fundamental characteristic it should be elevated to prime position. Geological occurrence, structure, mineralogical constitution, the lithic accepted criteria for the discrimination of rock species were not restricted to such Devonian aggregate rock province, is first to be interpreted in terms of the rock-forming minerals which might be expected to be formed when the magma crystallizes, e.g., quartz felspars of various kinds, olivine, aegirninite, felspar, biotite, muscovite, hornblende, etc., which are found into groups strictly according to the relative proportion of these minerals to one another. There is no need here to describe the mineralogical classification of rocks as it was done very clearly in their treatise (Quantitative Classification of Igneous Rocks, Chicago, 1902), and there is no indication that even in the United States it will ever displace the older classifications.

In discussing a sequence of events within a period and a restricted area certain features which distinguish them as a whole or more or less completely from other similar assemblages. Such groups are often said to the "petrological province." Excellent examples of this are furnished by the Devonian igneous rocks of southern Norway as described by Brögger, the Tertiary rocks of the Hebrides (Hacker), the Italian lavas on the Adriatic coast of the Adriatic north of the see, etc. These are rocks which girdle the Pacific (Andes, Cordillera, Japan, &c.), and those which occur on the volcanic islands of the Atlantic, show the same phenomena. Each of these groups has been formed presumably from a single magma, and yet the magmas which formed them have operated for a period which while necessarily prolonged was not of vast duration in a geological sense.

On the other hand, each of the great suites of eruptive rocks which constitute such a petrological province embraces a great range of types. Prolonged eruptions have in a few cases a somewhat monotonous character, owing to the fact that the same source of molten material was the seat of a single eruptive period and a restricted area. Thus the Hawaiian Islands are mostly basaltic, as are those of Oregon, Washington and the Deccan, all of which form geological masses of enormous magnitude. But it is more usual to find basaltic and andesitic lavas and their associated xenoliths within a single eruptive complex. The process by which a magma splits up into a variety of partial products is known as "differentiation." Its importance from the standpoint of theoretical petrology is very great, but in practical mineralogical observation it must be recognized that the earlier lavas are of intermediate character and that basic alternate with acid during the later stages of the volcanic history. Of these lavas are those which have been in consolidation yielded a variety of petrochemical types often widely divergent. This is best shown by great plutonic bosses which may be regarded as having once been vast subterranean spaces filled with a single nearly homogeneous liquid magma. Cooling took place gradually from the outer surfaces where the igneous rock was in contact with the surrounding strata. The resultant laccolite (Gr. λακκόλητη, pit, crater, λάκτως, stone), stock or boss, may be divided into three main kinds, each of which contains a great diversity of crystalline rocks. Thus peridotite, gabbro, diorite, tonalite and granite, are often associated, usually in such a way that the more basic are the first-formed and lie nearest the lens of magma. In some cases, however, conditions are such that occasionally, the edges being highly acid while the central parts consist of more basic rocks. Sometimes the later phases penetrate into and vein the earlier; evidently there has been some movement due to temporary increase of pressure when part of the laccolite was solid and part still in a liquid state. This links these phenomena with those above described where successive emissions of different character have proceeded outwards from the focus.

According to modern views two explanations of these facts are possible. Some geologists hold that the different rock faces are due to one or more "differentiation" processes, the separation of the more basic from the more acid, etc., part of the magma by the molten magma ("assimilation"). Effects of this kind are to be expected, and have been clearly proved in many places. There is, however, a general reluctance to admit that they represent the principal formative process. Most workers hold that these phenomena do not as a rule show any relation to the sedimentary or other materials which may be supposed to have been dissolved; and that no such processes are known to have gone on the products are usually of abnorml character and easily distinguishable from the common rock types.

Hence it is generally supposed that differentiation is to be accounted for by the removal of some portion of the magma, splitting up of a magma into dissimilar portions, each of which consolidates as a distinct kind of rock. Two factors can be selected as probably most potent. One important factor is cooling and another is the possibility of the influence of the least soluble substances will tend to diffuse towards the cooling surfaces (Ludwig-Soret's principle). This is in accordance with the majority of the observed facts and is probably a vera causa of part of the magma has not necessarily to be solution of mineral rocks. When solidifies the minerals which crystallize follow one another in a more or less well-defined order, the most basic (according to Rosenbusch's law) being first to separate out. That in a general way the peripheral portions of a laccolite consist of those fractions which were early basic minerals suggests that the sequence of crystallization helps largely in determining the succession (and consequently the types) of rocks. Gravity also may play a part, for it is proved that in a solution at rest the heaviest components will be concentrated towards the base. This must, however, be of secondary importance as in laccolites the top portions are usually the most basic. The other minerals, veins, volacanic, intrusive, etc., may be due to the gradual solution of the earlier formed laves which may dissolve a portion of the others and as the temperature falls and the conditions change a range of liquids differing in composition may be supposed to arise.

All igneous magmas contain dissolved gases (steam, carbonic acid, sulphurated hydrogen, chlorine, fluorine, boracic acid, &c.). Of these water is the principal, and was formerly believed to have percolated downwards from the earth's surface to the heated rocks below, but is now generally admitted to be an integral part of the magma. Many peculiarities of the structure of the plutonic rocks as contrasted with the lavas may reasonably be accounted for by this. The gasses, which were produced in the deep-seated masses slowly cooled, while they were promptly given up by the superficial eruptions. The acid plutonic or intrusive rocks have never been reproduced by laboratory experiments, and the theoretical study of the phenomena of the rock-chains has been in those in which special provision was made for the retention of the "mineralizing" gases in the crucibles or sealed tubes employed. These gases often do not enter into the composition of the rock- formation at all. As these are often acid, &c. Hence as crystallization goes on the residual liquid must contain an ever-increasing proportion of volatile constituents. It is conceivable that in the final stages the still uncrystallized portions of the granite have no inclination to be solution of mineral matter in superheated steam than to a dry igneous fusion. Quartz, for example, is the last mineral to form in a granite. It bears much of the stamp of the quartz which we know has been deposited in the formation of granite innumerable. It is at the same time true that these infusible of all the common minerals of rocks. Its late formation shows that in this case it arose at comparatively low temperatures and points clearly to the special importance of the gases of the magma in determining the final composition of the rock.

When solidification is nearly complete the gases can no longer be retained in the rock and make their escape through fissures in the surface layer. The minerals of the rocks which they traverse, and instances of their operation are found in the kaolinitization of granites, turmenization and formation of greisens, deposit of quartz veins, stanniferous veins, and "pneumatolytic" processes. Some of these are known as propylitization. These "pneumatolytic." (Gr. πνευμα, spirit, vapour, πνευματικός, to loose, dissolve) processes are of the first importance in the genesis of many ore deposits. They are a real phenomenon and not postulated to itself and constitute the terminal phases of the volcanic sequence.

The complicated succession from basic (or ultrabasic) to acid types exemplified in the history of many magmas is reflected with

1 The term "propylit" (Gr. πνευματικός) was found by Richtofen to a volcanic rock which is supposed to have marked a new epoch in volcanic geology (see ANDEREY).
astonishing completeness in the history of individual products. In each class of rock crystallization follows a definite course. The first crystals to separate belong to a group known as the basic minerals; the next in order includes zircon, sphene, iron oxides; then follow in order olivine, augite, hornblende, biotite, plagioclase, felspar (beginning with the varieties most rich in lime and ending with those which contain mainly potash felspar and feldspathoids). Many exceptions to this rule are known; the same mineral may crystallize at two different periods; two or more minerals may crystallize simultaneously or the stages in which they form may overlap. Sometimes there may be stages in the history of the rocks, of cases. Expressed in this way: the more basic minerals precede the less basic; it is not as known by Rosenbusch's law.

Petrology is sometimes supposed to be这话以一种更为复杂的语言来表达。
the processes involved in the formation of igneous rocks cannot be successfully handled. But every day sees an increase in the amount of data available, and encourages us to believe that sooner or later some of the simpler igneous rocks at any rate will be completely explained by physical principles.

Post-volcanic Changes.

Rock masses of igneous origin have no sooner consolidated than they begin to change. The gases with which the magma is charged are slowly dissipated, lava-flows often remain hot and the cooling of the soil, but of more recent years. These gases attack the components of the rock and deposit new minerals in cavities and fissures. The beautiful zeolites, so well known to collectors of minerals, are largely of this origin. Even before these 'post-volcanic' changes have ceased atmosphere-dissolved gas position begins. Rain, frost, carbonic acid, oxygen and other agents operate continuously, and do not cease till the whole mass has crumbled down and most of its ingredients have been resolved into their ore elements. The products of these chemical changes are generally considered unessential; rocks are classified and described as if they were ideally fresh, though this is rarely the case in nature.

Evaporitic change (secondary processes) may be arranged under a number of headings, each of which is typical of a group of rocks or rock-forming minerals, though usually more of one than another of these alterations will be found in progress in the same rock. Silicification, the replacement of the minerals by crystalline or crypto-crystalline silica, is most common in acid rocks, such as rhyolite, but is also found in serpentine, &c. Kaolinization of the mica of the country rock, and the conversion of minerals of igneous rocks, into kaolin (along with quartz, muscovite, &c.); it is best shown by granites and syenites. Serpentinitization is the alteration of olivine to serpentine (with magnetite); it is typical of certain lavas, is occasioned by the presence in it of ferro-magnesian minerals, and the alteration secondary hornblende replaces augite; this occurs very generally in diabases; chloritization is the alteration of augite (biotite or hornblende) to chlorite, and is seen in many diabases, dolomites, and gneiss. Epidotization occurs also in rocks of this group, and consists in the development of epidote from biotite, hornblende, augite or pleioclace felspar.

The sedimentary rocks, which constitute the second great group, have many points in common that distinguish them from the igneous and the metamorphic. They have all originated on the surface of the earth, and at the period of their formation were exposed only to the temperature of the air and to atmospheric pressure (or the pressures which exist at the bottoms of seas and lakes); the materials in most cases are liable to change when exposed to moist air or sea, and many of them are hydrated (chlorite, micas, &c.), or oxidized (iron ores), or contain carbonic acid (calcite, dolomite). The extent, however, to which this is the case depends largely on the rapidity with which they have accumulated; coarse rocks quickly piled up often consist of materials only partly weathered. When crystalline, the sedimentary rocks are usually soluble at low temperatures. The members of this group occur in beds or strata, hence they are often known as the stratified rocks; the upper beds are always of later formation than those which underlie them, except (as may happen when great disturbance has taken place) the whole series is inverted or overturned. Many of them, to form their skeletons, have been fished from this moving water (rivers, currents, &c.) and are grouped together as "aqueous" rocks; others have been deposited by the wind in deserts, on sandy beaches, &c. (these are "aeolian" rocks.). The remains of animals or of plants, modified by the action of time, pressure and percolating water. Lastly, we find beds of crystalline nature, such as rock-salt and gypsum, which have been formed by the desiccation of saline waters; other crystalline stratified rocks, such as dolomite and many beaded iron-stones, are replacement products due to the introduction of the original mineral matter in solution, which replaced the original rock mass partially or wholly.

When the rocks exposed at the earth's surface give way before the attack of the agencies of denudation, they crumble down and are removed by water, or percolating water. Once (sand, clay and angular débris) insoluble in carbonated waters; the other part is dissolved and washed away. The undissolved residues, when they finally come to rest, form clastic sedimentary rocks (sandstones, conglomerates, shale, &c.). The dissolved portions are partly transferred to the sea, where they help to increase its store of salts, and may again be precipitated as clastic sedimentary rocks; but they are also made use of by plants and by animals to form their skeletons or with other tissues. From this latter portion the rocks of organic origin are built up. These may also contain certain ingredients derived from the atmosphere (nitrogen, carbon in coals, &c.).
carbonaceous, siliceous, ferruginous, and so on. The calcareous organisms, including pelecypods, crinoids, corals, brachiopoda, mollusca, polyclad, &c. Most of them, however, contain a mixture of organisms. By crystallization and metamorphic changes they often lose their organic structures; metamorphism of this kind has the same effect on the original carbonaceous object as on essentially plant deposits; they include peat, lignite and coal. The siliceous organic rocks include radiolarian and diatom oozes; in the older formations they occur as radiolarian clints. Flint nodules are common; they consist of large masses of radiolarian silt which have been dissolved and redeposited by concretionary action. Some kinds of siliceous silt may be produced by organisms inhabiting hot silicified waters. Calcareous ooliths in the same way may be produced by the lime-secreting minute planktonic and benthonic forms, which also may be of organic rather than merely chemical origin. The phosphatic rocks so extensively sought after as sources of fertilizer against agricultural deficiencies contain the remains of most past ages. In the Permian formation, since they owe their substance to the remains of certain varieties of animals which secrete a phosphatic skeleton; but most of them no longer show organic structures but have been converted into a siliceous substance.

All sediments are at first in an incoherent condition (e.g. sands, clays and gravels, beds of shells, &c.), and in this state they may remain for an indefinite period. Millions of years have elapsed since some of the ocean floor, yet they are quite friable (e.g. the London Clay) and differ little from many recent accumulations. There are few exceptions, however, to the rule that with increasing age rocks become less friable, and the older they are the more likely is it that they will have the firm consistency generally implied in the term "rock." The process of cementation on which it is based is at times a very slow one, and may take many millions of years. More generally it is a very rapid process, being accelerated by the increased pressure produced by superincumbent masses, and to some extent also by the rise of temperature which inevitably takes place in rocks buried to some depth beneath the surface. The rise of temperature, however, is not always great; we know more than one instance of sedimentary deposits which have been buried beneath four or five miles of similar strata (e.g. parts of the Old Red Sandstone), yet no perceptible difference in texture and cementation has come to light. We can only take note at the top of the series and near its base. The redeposited cementing material is most commonly calcareous or siliceous. Lime-silicate-hornfels, the tuffaceous or argillaceous accumulation of shells, corals, &c., become compacted into firm rock in this manner; and the process often takes place with surprising ease, as for example in the deeper parts of coral reefs, or even in wind-blown masses of shelly sand exposed merely to the action of rain. The condensed substance may be regularly deposited in crystalline continuity on the original grains, where these were crystalline; even and sandstones (such as Kentish Rag) a crystalline matrix of calcite often occurs, as if the sand itself were crystalline. The change is often so complete that calcite to dolomite, by forming new crystalline masses in the interior of the rock, usually also accelerates consolidation. Silica is less easily soluble in ordinary waters, but even this ingredient of sandstone is not uncommonly redeposited. Sandstones are held together by an infinitesimal amount of colloidal or cryptocrystalline silica; when freshly dug from the quarry they are soft and easily trimmed, but after exposure to the air for some time they become much harder, as their siliceous cement sets and passes into a rigid condition. Others contain fine scales of kaolin or mica. Argillaceous materials may be compacted by mere pressure like graphite and other scaly minerals. Oxides and carbonates of iron play a large part in many sedimentary rocks and are especially important as colouring matters. The red sands and limestones, for example, which are so abundant, contain admixtures of ferric oxide. "Ferriferous" is a synonym of "reddish". Finely divided states gives a red hue of all rocks in which it is present. Limonite, on the other hand, makes rocks yellow or brown; oxides of manganese, asphalt and other carbonaceous substances are the cause of the black colour of many sandstones. Bluish tints result sometimes from the presence of phosphates or fluor spar; while green is most frequently seen in rocks which contain glauconite or chlorite.

Metamorphic Rocks.—The metamorphic rocks, which form the third great subdivision, are even more diverse than the igneous and sedimentary. They include representatives of nearly all kinds of original formations, and characteristic being that they have all undergone considerable alterations of structure or in mineral composition. The agencies of metamorphism (q.v.) are of two kinds—thermal and regional. In the former case contact with intrusive igneous masses, such as granite, laccolites or dikes, have indurated and recrystallized the original rock. In the second case the actions are more complex and less clearly understood; it is evident that pressure and interstitial movement have had a powerful influence, possibly assisted by rise of temperature. In thermal or contact alteration the rocks are baked, indurated, and often in large measure recrystallized. In regional metamorphism recrystallization also goes on, but the final products are usually schists and gneisses. It is often very difficult to distinguish the two classes of metamorphic rocks, a glance, and they may conveniently be considered separately.

When a rock is contact altered by an igneous intrusion it very frequently becomes harder, more crystalline and more lustreous, owing to the development of many small crystals in its mass. Many altered rocks of this type were formerly called "hornfelses" (horn for the horn that is) but the term Hornfels is now largely used by geologists to signify those fine grained, compact, crystalline products of thermal metamorphism. A shale becomes a dark argillaceous hornfels, full of tiny green hornblende, a mafit or impure limestones change to a grey, yellow or greenish lime-silicate-hornfels, tough and splintery, with abundance of augite, garnet, wollastonite and other minerals in which lime is an important component. A diabase or andesite becomes a diabase hornfels or hornblende hornfels and a partial recrystallization of the original felspath. A chert or flint becomes a finely grained quartzite, a slate becomes a mica quartzite, their original structure and texture are retained, although they may have their shapes preserved, though entirely recrystallized. If the many contact altered lavas the steam cavities are still visible, though their contents have usually entered into new combinations to form minerals different from the original. The minute structure is, however, disappear, often completely, if the thermal alteration is very profound; thus small grains of quartz in a shale are lost or blend with the surrounding particles of clay, and the fine ground-mass of latter is entirely composed of quartz.

By recrystallization in this manner peculiar rocks of very distinct types are often produced. Thus shales may pass into cordierite rock, they may show beautiful crystals of analastone (and chalastite, Pl. IV., fig. 9), staurolite, garnet, or hornblende, and a small amount of mica (both muscovite and biotite) is simultaneously formed, and the resulting product has a close resemblance to many kinds of mica schist. Basalt and some other rocks may be converted into coarse crystalline marbles (Pl. IV., fig. 4); but if there was an admixture of clay or sand in the original rock such minerals as garnet, epidote, idocrase, wollastonite, will be present. Sandstones when greatly heated may change into coarse quartzites composed of large clear grains of quartz. These more intense stages of alteration, not so commonly seen in igneous rocks, possibly because their minerals, being formed at high temperatures, are not so easily transformed or recrystallized.

In a few cases rocks are fused and in the dark glassy product minute crystals of spinel, sillimanite and cordierite may separate out. Shales are occasionally thus altered by basalt dikes, and felspatites and cordierite are formed. Very frequently, however, the felspathic minerals may be induced in shales by the burning of coal seams or even by an ordinary furnace.

There is also a tendency for interfusion of the igneous with the sedimentary rock. Granites may absorb fragments of shale pieces of basalt. In that case hybrid rocks arise which have not the characters of normal igneous or sedimentary rocks. Such effects are scarce and are usually easily recognized. Sometimes an invading granite magma permeates the rocks around, filling its joints and planes of bedding, &c., with threads of quartz and felspathic minerals are formed, and the so-called granite gneisses and "hornblende gneisses" may be thus produced. Such rocks are known as "granitic gneisses". This type of metamorphism is known as regional metamorphism and is common in many parts of the world. It involves the recrystallization of rocks under high pressure and temperature conditions, leading to the formation of new minerals and structures.

Regional Metamorphism.

These rocks are often called "metamorphic" or "metasedimentary" rocks, and they are characterized by the presence of minerals such as garnet, staurolite, andalusite, and their textures may range from fine-grained schists to coarser gneisses. The processes of regional metamorphism include the recrystallization of pre-existing minerals, the formation of new minerals, and the alteration of original mineral assemblages. The effects of regional metamorphism are often visible in the form of foliation, mineral banding, and the development of new mineral assemblages that are characteristic of the specific geological setting and temperature conditions.
FIG. 1.—PHONOLITE, TEPLITZER SCHLOSSBERG, BOHEMIA \((x \times 12)\).

The large white crystal is felspar, the smaller ones are nepheline having six-sided and four-sided sections. The dark mineral in the ground-mass is aegirine.

FIG. 2.—LEUCITOPHYRE, RIEDEN, EIFFEL, GERMANY \((x \times 15)\).

A porphyritic clear crystal of leucite lies near the centre of the field; towards the margins are nosean crystals with clear centres and broad black edges. The black spots are aegirine and aegirine-augite, and in the ground-mass small prisms of white nepheline may be seen.

FIG. 3.—LEUCITE-BASANITE, VESUVIUS \((x 8)\).

The rounded central crystal is leucite, showing zones of inclusions and well-marked cracks; below it is a dark-brown augite, and olivine occurs near the bottom of the field. There are numerous rectangular white sections of plagioclase felspar. The dark ground-mass is partly vitreous.

FIG. 4.—HYPERSTHENE-ANDESITE, ALWYN, CHEVIOTS, ENGLAND \((x \times 10)\).

A porphyritic rock with phenocrysts of white plagioclase felspar and of pale-brown augite and hypersthene in a fine ground-mass, partly glassy.

FIG. 5.—OLIVINE-BASALT, CRAIG-LOCKHART, EDINBURGH, SCOTLAND \((x \times 10)\).

Two large crystals of augite above and below, and of olivine (right and left) lie in a crystalline ground-mass of plagioclase felspar, augite, and magnetite. The olivine has been altered to fibrous green serpentine, and the pseudomorphs show traces of the original cleavage cracks.

FIG. 6.—OPHIC OLIVINE-DOLERITE, DUN FION, ARRAN, SCOTLAND.

The white mineral is plagioclase felspar, which penetrates a large dark crystal of augite in ophitic manner. At the bottom of the field there are a few grains of olivine, colourless, but with strongly marked cracks.

FIG. 7.—OLIVINE-GABBRO, VOLPERSDORF, SILESIA \((x \times 10)\).

Felspar occurs towards the edges of the field and surrounds a cluster of diachlase (with strong, dark, parallel lamination) and of olivine (covered with a black network of secondary magnetite).

FIG. 8.—PERIDOTITE, ELBA \((x \times 10)\).

The rounded crystals are olivine, weathering as usual to magnetite and serpentine along its cracks and borders. The dark interstitial substance is enstatite weathered to bastite.

FIG. 9.—SERPENTINE, COLMONELL, AYRSHIRE, SCOTLAND \((x \times 12)\).

In this rock the process of serpentinization, seen in the previous figure, is complete. No olivine remains, but a meshwork of magnetite indicates the position of the cracks in the original crystals. The cloudy, dark streak above the centre is bastite replacing primary enstatite.
Fig. 1.—Pebby Grit, Banff, Scotland (x 12).

The white pebbles are quartz with irregular cracks and streaks of fluid inclusions. The matrix is a dark, semi-opaque mixture of clay and small sand-grains.

Fig. 2.—Volcanic Tuff, Arthur's Seat, Edinburgh (x 8).

A fragmental volcanic rock with small lapilli of basalt; these are vesicular and contain little felspar crystals. Broken felspars also lie scattered through the rock.

Fig. 3.—Crinoidal Limestone (Carboniferous), Clifton, near Bath, England (x 10).

The oolitic grains are round or oval, with concentric zoning; in their interior there is sometimes a shell fragment or other nucleus. The interstitial matrix is clear, granular, crystalline calcite. The rock contains fragments of echinoderms, brachiopods, and other fossils.

Fig. 4.—Marble, Carrara, Italy (x 8).

A section of well-known statuary marble which consists entirely of calcite in small irregular crystals closely fitted together.

Fig. 5.—Oolitic Chert (Cambrian), Sutherlandshire, Scotland (x 15).

This has been once an oolitic limestone, but the calcite has been entirely replaced by silica with perfect preservation of the oolitic structure.

Fig. 6.—Mylonite Durness, Sutherlandshire (x 8).

This well-banded rock was once a crystalline gneiss which has been greatly crushed by earth-movements, and has been ground down into a fine aggregate of quartz, felspar, and mica. The banding is due to internal flow under great pressure.

Fig. 7.—Slate, Wadebridge, Cornwall (x 20).

A fine-grained clay rock with small clear spots of quartz and minute scales of mica, chlorite, &c. The parallel arrangement of the latter is the cause of cleavage. Obscure dark lines cut across the rock and indicate the development of a secondary cross-cleavage or slip-cleavage.

Fig. 8.—Mica-Schist, Blair-Atholl, Perthshire, Scotland (x 32).

A clay rock like the preceding one, but more metamorphic and coarsely crystalline. The clear spots are quartz and the bladed mineral between them is brown and white mica (biotite and muscovite).

Fig. 9.—Chastolite-Slate, Skiddaw, Cumberland (x 17).

A clay rock affected by contact metamorphism attended by the production of needles of chastolite, which have in transverse section a diamond-shape with dark enclosures at their centres and a dark cross radiating to their corners.
PETRONEIL—PETRONIUS

will be visible. In gneisses these alternating folia are thicker and less regular than in schists; they are often lenticular, dying out rapidly. Gneisses also, as a rule, contain more felspar than schists do, and they are tougher and less fissile. Contortion or crumpling (Biegung des Gesteins) is not uncommon in gneisses. This is the splitting faces are undulose or puckered. The origin of schistosity or foliation is not perfectly understood, but it is clear that in many cases it is due to pressure, acting in a direction perpendicular to the layers; in others, to a more or less parallel flow arranging the mineral particles while they are crystalizing.

Rocks which were originally sedimentary and rocks which were undoubtedly igneous are converted into schists and gneisses, and if one of these rocks is altered in such a way that it cannot be distinguished from another if the metamorphism has been great. A quartz-porphyry, for example, and a fine felspathic sandstone, may be changed to a gray-pink mica-schist. Usually, however, we may distinguish between a metamorphic formation and a gneissic rock on the basis of their color, texture, and mineralogy. Often the metamorphism is progressive, and if the whole district occupied by these rocks is searched traces of beugung of the metamorphic minerals are often found. The evidence may be obtained showing that we are dealing with a group of altered sediments. In other cases intrusive junctions, chilled edges, contact alteration or porphyritic structure may prove that in its original condition the rock was a volcanic or intrusive rock. The appeal is often to the chemist, for there are certain rock types which occur only as sediments, while others are found only among igneous masses, and, however advanced the metamorphism may be, it rarely more than converts the igneous rock into a coarser grained variety. For example, granite quartz porphyry, for example, as limestones, calc-schists, dolomites, quartzites and aluminous shales have very definite chemical characters which distinguish them even when completely recrystallized.

Rocks which are characterized as a gneissic rock by the minerals they consist of, and this depends principally on their chemical composition. We have, for example, a group of metamorphic limestone rocks, such as hornblende-biotite schists, gneiss, and dolomites; many of these contain silicates such as mica, tremolite, diopside, scapolite, quartz and felspar. They are derived from calcareous sediments of different degrees of purity. Another group is rich in quartz (quartzites, quartz schists and quartz gneisses), with variable amounts of white and black mica, garnet, felspar, zoisite and hornblende. These are well sandstones and arenaceous rocks. The gneisses may readily be identified to represent several groups, and other rocks, especially the gneisses, are also schistose ironstones (haematite-schists), but metamorphic beds of salt or gypsum are exceedingly uncommon. Among schists of igneous origin we may mention the silicic calc-schists, the foliated sepia (argillaceous slates), and alkali gneisses, which are found as mica-schists, porphyroids and banded halleflintas, which have been derived from rhyolites, quartz-porphyrites and acid tuffs. The majority of gneiss, however, are altered clays and pass into the normal sedimentary rocks through various types of phyllite and mica-slates. They are among the most common metamorphic rocks; some of them are gneiss and others are calcareous. They are composite and coarsely crystalline greywackes, and form a well-defined group not difficult to recognize, from the abundance of black and white micas in their thin, greenish, schistose character. As a special subgroup we have the andalusite-, staurolite- and greenschist facies of the same type. The gneisses, which usually make their appearance in the vicinity of gneissic rocks, and have presumably been affected by contact alteration. The more coarsely foliated gneisses are almost as frequent as the gneisses, and present a great variety of types differing in composition and in appearance. They contain quartz, one or more varieties of felspar, and usually mica hornblende or augite, often garnet, iron oxides, &c. Hence in composition they resemble granites, differing principally in the arrangement of the feldspars. Many of them have "augen" or large elongated crystals, mostly felspar but sometimes quartz, which are the crushed remains of porphyritic minerals; the foliation of the matrix winds around these augen, or "augenrocks," as they arc called. The more quartziferous metamorphic rocks, but sometimes a conglomerate bed simulates a gneiss of this kind rather closely. There are other gneisses, which are derived from sandstones and arkoses, arkoses, the majority of which; they mostly contain biotite and muscovite, but the hornblende and pyroxene gneisses are usually igneous rocks allied to the hornblende-granites and quartz-diorites. These three morphic forms of dolerite, basalt and the basic igneous rocks generally have a distinctive facies as their pyroxene and olivine are replaced by dark green hornblende, with often epidote, garnet and biotite. These rocks have a well developed foliation, as the pyroxene and olivine are separated by an interlocking arrangement. The majority of amphiboles, hornblende-schists, foliated epidiorites and green schists belong to this group. Where they are least altered they pass through chloritic schists into sheared diabases, finally becoming the schists in which sections in the metamorphic belts of igneous minerals and structures occur in greater or less profusion.

PETRONIUS, a 16th or 17th century fire-arm, defined by R. Barret (Theorie and Practique of Modern Wores, 1538) as a "horsman's peece." It was the fire-arm which developed on the one hand into the pistol and on the other into the carbine. The name (Fr. petrinel for poitrinal) was given to the weapon either because it was fired with the butt resting against the chest (poitrine, Lat.pectus) or because it was carried slung from a belt across the chest.

PETRONIUS (G. (?); Petronius Arbiter), Roman writer of the Neronian age. His own work, the Satires, tells us nothing directly of his fortunes, position, or even century. Some lines of Sidonius Apollinaris refer to him and are often taken to imply that he lived and wrote at Marseilles. If, however, we accept the identification of this author with the Petronius of Tacitus, Nero's courtier, we must suppose either that Marseilles was his birthplace or, as is more likely, that Sidonius refers to the novel itself and that its scene was partly laid at Marseilles. The chief personages of the story are evidently strangers in the towns of southern Italy where we find them. Their Greek-speaking names (Encolpius, Aseylos, Gicon, &c.) and literary training suggest that the characters of the novel are of the 1st or 2nd century A.C. The high position among Latin writers ascribed by Sidonius to Petronius, and the mention of him beside Menander by Macrobius, when compared with the absolute silence of Quintilian, Juvenal and Martial, seem to agree the opinion that the Satires was a work of the age of Nero. But Quintilian was concerned with writers who could be turned to use in the

1 The MSS. of the Satires give no praenomen. Tacitus's Petronius is Gaius, though the elder Pliny and Plutarch call him Titus. The name Arbiter, given him by later writers, is not an ordinary cognomen. He may have been bestowed on him by contemporaries from the fact that his judgment was regarded as the criterion of good taste.
PETRONIUS

education of an orator. The silence of Juvenal and Martial may be accidental or it is possible that a work so abnormal in form and substance was more highly prized by later generations than by the author's contemporaries.

The more important book gives us an impression of the character and genius of its author with the elaborate picture of the courtier in Tacitus certainly suggests the identity of the two. Tacitus, it is true, mentions no important work as the composition of his C. Petronius; such a work as the Satyræ he may have regarded as beneath that dignity of which he so proudly realized. The care he gives to Petronius's portrait perhaps shows that the man enjoyed greater notoriety than was due merely to the part he played in history. "He spent his days in sleep, his nights in attending to his official duties or in amusement, by his dissolute life he had become as famous as other men by a life of energy, and he was regarded as an ordinary proletarian but as an accomplished voluptuary. His reckless freedom of speech, being regarded as frankness, procured him popularity. Yet during his provincial governorship, and later when he held the office of consul, he had shown vigour and capacity for affairs. Afterwards returning to his life of vicious indulgence, he became one of the chosen circle of Nero's intimates, and was looked upon as an absolute authority on questions of taste (arbiter elegantiae) in connexion with the science of luxurious living." 1 Tacitus goes on to say that this excited the jealousy of Tigellinus, an accusation followed, and Petronius committed suicide in a way that was in keeping with his life and character. He selected the slow process of openning a vein and letting the blood flow into the sea, bound up again, whilst he conversed on light and trifling topics with his friends. He then dined luxuriously, slept for some time, and, so far from adopting the common practice of flattering Nero or Tigrillus in his will, wrote and sent under seal to Nero a document which professed to give, with the names of his partners, a detailed account of the abominations which that emperor had practised.

A fact confirmatory of the general truth of this graphic portrait is added by the elder Pliny, who mentions that just before his death he destroyed a valuable murrhine vase to prevent its falling into the imperial hands. Do the traits of this picture agree with that impression of himself which the author of the Satyræ has left upon his work? That we possess therein part of the document sent to Nero is an impossible theory. Our fragments profess to be extracts from the fifteenth and sixteenth books of the Satyræ: Petronius could not have composed one-tenth even of what we have in the time in which he is said to have composed his memoir to Nero. We may be sure too that the latter was very frank in its language, and treated Nero with far greater severity than the Banquet treats Trimalchio. On the other hand, it is clear that the creator of Trimalchio, Encolpius and Giton had the experience, the inclinations and the literary gifts which would enable him to describe with forcible mockery the debaucheries of Nero. And the impression of his personality does in another respect correspond closely with the Petronius of the Amours—in the union of immoral sensuality with a rich vein of cynical humour and admirable taste.

The style of the work, where it does not purposely reproduce the solecisms and colloquialisms of the vulgar rich, is of the purest Latin of the Silver age. 2 Nor would there be any point in the verses on the capture of Troy and the Civil War at any of the other era than that in which Nero's Troica and Lucan's Pharsalia were fashionable poems. The reciting poet indeed is a feature of a later age also, as we learn from Martial and Juvenal. But we know that Tacitus of the Cato and his many conspicuous in Trimalchio's Banquet fell out of fashion after Nero (Ann. vi. 15).

Of the work itself there have been preserved 141 sections of a narrative, in the main consecutive, although interrupted by frequent gaps. The name Satyræ, given in the best MSS., implies that it belongs to the type to which Varro, imitating the Greek Menippus, had given the character of a medley of prose and verse composition. But the string of fictitious narrativeness which by the medley is held together is something quite new in Roman literature. This careless prodigal was so happily inspired in his devices for amusing himself as to introduce to Rome and thereby transmit to modern times the novel based on the ordinary prejudices of contemporary life and the premises of such novels as Gil Blas and My Burial Random. There is no evidence of the existence of a regular plot in the fragments, but we find one central figure, Encolpius, who professes to narrate his adventures and describe all that he saw and heard, whilst allowing various other personages to exhibit their peculiarities and express their opinions dramatically.

The fragment opens with the appearance of the hero, Encolpius, who seems to be an itinerant lecturer travelling with a companion named Ascylos and a boy Giton, in a portico of a Greek town, and, after leaving the lecture on a work of Cicero, resulting from the prevailing system of education, is replied to by a rival declaimer, Agamenon, who shifts the blame from the teachers to the parents. The central personnages of the story next go through various lives and experiences, at one time entertaining with ostentation and grotesque extravagance a number of men of his own rank but less profligate, and sometimes by the ordinary talk of the guests about their neighbours, about the weather, about the hard times, about the public games, about the entertainments of their guests, and their own recognitions, as well as the same kind of vulgarity and pretension which the satirist of all times delights to expose in the lillitrate and ostentatious millionaires of the age. Next day Encolpius separates from his companions to gloat on a rusty, and, after a night in the town on his revenge, enters a picture gallery, where he meets with an old poet, who, after talking sensibly on the decay of art and the inferiority of the painters of the age to the old masters, proceeds to illustrate a picture of the capture of Troy by some verses on that theme. This ends in those who are walking in the adjoining colonnade driving him out with stones. The scene is next on board ship, where Encolpius finds he has fallen into the hands of some old enemies. He escapes them, and arrives at Athens, where he goes to shore in the neighbourhood of Crotona, where, as the inhabitants are notorious fortune-hunters, the adventurers set up as men of fortune. The fragment ends with a new set of questionable adventures, in which we may discern an element of plot, the main one consisting in the marriage of Encolpius in Athens to a woman named Circe, a priestess of Priapus, and a certain matron who leaves them her heirs, but attaches a condition to the inheritance which even Encolpius might have shrunk from fulfilling. If we suppose the author of this work to have been animated by another motive than the desire to amuse himself, it might be that of convincing himself that the world in general was as bad as he was himself. Juvenal and Swift are justly regarded as among the very greatest of satirists, and their estimate of human nature is perhaps nearly as unfavourable as that of Petronius; but their attitude towards human degradation is not one of complacent amusement; their reactions to the realization of their hopes, like that of Petronius, the absence of sympathy. Martial does not goat over the vices of which he writes with cynical frankness. He is perfectly aware that they are vices, and that the reproach of them is the worst that can be cast on any one. And, further, Martial, with all his faults, is, in his affections, his tastes, his relations to others, essentially human, friendly, generous, true. There is perhaps not a single sentence in Petronius which implies any knowledge of or sympathy with the wide range of affectations of vanity or science or honour, or even the most elementary goodness of heart.

1 For the whole question of possible predecessors and Petronius's relation to the extant Greek romances see W. Schmidt, "Der griechische Roman" in Jahrbücher für das klass. Altertum, &c. (1904). One would certainly have expected the realistic tendency which was so strong in the New Comedy of Plautus and the Satyræ, to have borne this fruit before the first century of our era.—(W. C. Su.)

2 Such a sentence in Petronius which implies any knowledge of or sympathy with the wide range of affectations of vanity or science or honour, or even the most elementary goodness of heart.
The work has reached us so fragmentary and mutilated a shape that we may of course altogether have missed the key to it; it may have been written in a vein of reserved and powerful irony, of the type realized in our modern Jonathan Wild or Barry Lyndon. Otherwise we must admit that, in the entire divorce of intellectual power and insight from any element of religious feeling, the work is an exceptional phenomenon in literature. For, as a work of original power, of humorous representation, of literary invention and art, the fragment deserves all the admiration which it has received. We recognize the arbiter elegantiarum. It seems as if the remarks scattered through it on education, on art, and on poetry and eloquence. There is a true feeling of nature in the description of a grove of plane-trees, cypresses and pines:

"Has inter ludebat aquis errantium annuis
Spumus et querculo vexabat rope lapillus."

And some of the shorter pieces anticipate the terseness and elegance of Martial. The long fragment on the Civil War does not stand out so much as do the others, perhaps as of entering into rivalry with the poem of Lucan. In the epigram extemporized by Trimalchio late on in the banquet:

"Quod non expectes, ex transverso fit—
Et supra nos Fortuna negotia curat,
Quare da nobis vina Falerna, puer,"

we have probably a more deliberate parody of the style of verses produced by the illiterate aspirants to be in the fashion of the day. We might conjecture that the chief gift to which Petronius owed his success was, not his literary but his humorous power. In Trimalchio and his various guests, in the old poet, in the cultivated, depraved and moody Encolpius, in the Chrysia, Quartinia, Pulaenias, &c., we recognize in living examples the play of those various appetites and instincts which satisfy the different demands of a vulgar and a more enlightened public. Another gift he possesses in a high degree, which must have availed him in society as well as in literature—the gift of story-telling; and some of the stories which first appear in the Saturae in Plautina have come to us with as much credit as with as abstract qualities. Another style he possesses in a high degree, which has made him popular, is his power of criticism, of the remarks scattered through in later times. His style, too, is that of an excellent talker, who could have discussed questions of taste and literature with the most cultivated of men of any time, as amusingly and with as much sense as any writer, with as much spirit, with as much wit, with as much good-humour. One phrase of his is often quoted by many who have never come upon it in its original context, "Horatii curiosa felicitas."

And it does not seem unlikely that the fragments of the Banquet of Trimalchio, with the other fragments of the work, was known. The best MS. of this type is a Leiden MS., a copy by Scaliger of one which seems to have belonged to Cujacius. Marinus Statilus (see, however, Ellis, Journal of Philology, 12, p. 266), discovered at Trau in Dalmatia a MS. containing the whole Banquet, which was first published at Padua in 1664.

The important editions are (1) with critical and explanatory notes: Burman (Amsterdam, 1743, with Heinsius's notes), and, of the Cena only, Friedländer (Leipzig, 2nd ed., 1896) and Lowe (Cambridge, 1904); (2) with critical notes: Böcher (Berlin, 1862, 4th ed., 1904). Translations into German in Friedländer's edition (complete, 1873), into French by D. Garnerie (complete, 1863), and into English in Lowe's edition (Cena only) and Bohm's series (complete). Lexicon to Petronius by Segballe and Lommatzsch (Leipzig, 1898). Critics in 1886 in Harvard Studies, i.; Collignon, Étude sur Pline (Paris, 1892); Emile Thomas, L'Entres de la societé romaine d'àpres Pline (Paris, 1892); Hrzel, Der Dialoge. ii. (Leipzig, 1895); Tyrrell, Latin Poetry (London, 1895); Norden, Anthe Kunststofa i. (Leipzig, 1898); Henderson, Life and Prince of the Emperor Nero (London, 1903); Dill, Roman Society from Nero to Marcus Aurelius (London, 1905); and the various histories of Roman literature (especially Schanz, §§ 395 sqq.).

PETROPAVLOVSK, a town of West Siberia, in the government of Akmolensk, on the right bank of the Ishim river, and on the great Siberian highway, 170 m. by rail W. of Omsk. The population, 7850 in 1855, was 21,790 in 1900, of whom one-third were Mahomedan Kirghiz. The town carries on an active trade in cattle, furs, tea, wool, skins, cottons, woolen stuffs, corn, metal, metallic wares and spirits. The small fort of Petrovsk was founded in 1752, and was the military centre of the Ishim line of fortifications.

Petrovsk is also the name of a Russian seaport in Kamchatka, on the eastern shore of the Bay of Avacha, in 53° N. and 168° 44' E. The harbor is about a fathom deep, and for the best of the trade, this deal with the town consists merely of a few huts with some 400 inhabitants. Its naval institutions were transferred to Nikolaevsk after the attack of the Anglo-French fleet in 1855.

PETROZAVODSK, a town and an episcopal see of Russia, capital of the government of Olonets, on the west shore of Lake Onega, 190 m. N.E. of St Petersburg. Pop. (1865), 11,027; (1897), 12,521. Two cathedrals, built towards the end of the 18th century, a mining school, an ecclesiastical seminary and a government cannon-foundry are the chief public buildings and institutions. Peter the Great founded ironworks here in 1723, but they continued in operation only twenty-four years. The cannon-foundry was instituted in 1774. Petrozavodsk became the capital of the government of Olonets in 1802.

PETRUCI, Pandolfo (d. 1532), tyrant of Siena, spent the greater part of his youth in exile, on account of the civil strife by which his native town of Siena was torn; but on the triumph of the party of the Noveschi (those who supported the Council of Nine) in 1497 he was able to return home. On the death of his brother Giacopo, one of the most powerful men in the city, Pandolfo succeeded to all the latter's offices and emoluments (1497), thus becoming in fact if not in name master of Siena. By his marriage with Aurelia, daughter of Nicola Borghese, another very influential citizen, he still further strengthened his authority. But he soon began to abuse his power by selling public offices to
PETRUS AUREOLUS—PETTY

the highest hitters, or concentrating them on his followers. A plot was made to murder him, but he discovered the conspiracy in time, and his own father-in-law, who had been leader of the movement, was put to death. In 1498 he prevented the outbreak of war with Florence over the possession of Montepulciano, which had been a bone of contention between the two cities for over a hundred years. His attitude towards Cesare Borgia was exceedingly astute; at first he assisted him, and obtained from him with the favour of the French king the cession of Fiambino, but having subsequently aroused the suspicions of Borgia, the latter attempted to suppress Petrucci by inviting him to the latter meeting of Senigallia. The Siennese tyrant, however, did not fall into the trap, and although Borgia in 1502 obliged him to quit Siena, he returned two months later, more powerful than before. Petrucci supported Pisa in the war against Florence, but eventually, through the intervention of the pope and of the king of Spain, he made peace with the latter city, to which he gave back Montepulciano in 1512. As a reward for this action Pope Julius II. created his nephew cardinal. During his last days Petrucci abdicated his authority in favour of his son Borghese. He died at San Quirico di Osenna on the 21st of May 1572.

See Pecci, Memorie storico-critiche di Siena (Siena, 1755); U. G. Monfardino, P. Petrucci signore di Siena (Siena, 1899).

PETRUS AUREOLUS (Ortol), scholastic philosopher and monk of the Franciscan order, lived in the latter half of the 13th century, and died in Paris in 1321 just after his appointment as archbishop of Aix. He was one of the first to attack the realist doctrines of Duns Scotus, and is interesting mainly as the precursor of William of Occam in his revival of Nominalism. His earned him for the titles of Doctor Facundus and Doctor Abundans.

PETTENKOFEN, AUGUST VON (1821-1889), Austrian painter, was born in Vienna, was brought up on his father's estate in Galicia. Having decided to give up the military career on which he had started, he devoted himself to painting, taking for his subjects the simple scenes of the life on the dreary Puszta. His paintings are treasured for their fine qualities of colour, and for the sincerity with which the artist presents before us the uneventful melancholy life of Hungarian peasants and gipsies—without any theatrical pathos or forced humour. He was the inventor of the Petttenkofen box, an appliance for dissolving and redistributing cracked or discoloured varnish without friction or the dangerous use of chemicals. He died in Vienna in 1889.

PETTENKOFER, MAX JOSEPH VON (1818-1901), Bavarian chemist and hygienist, was born on the 2nd of December 1818 at Lichtenheim, near Neuburg. He was the nephew of Franz Xaver Pettenkofen (1783-1850), who from 1833 was surgeon and assistant to the Bavarian court and was the author of some chemical investigations on the vegetable alkaloids. He studied pharmacy and medicine at Munich, where he graduated M.D. in 1843, and after working under Liebig at Giessen was appointed chemist to the Munich mint in 1845. Two years later he was chosen extraordinary professor of chemistry in the medical faculty, in 1853 he received the ordinary professorship, and in 1865 he became also professor of hygiene. In 1894 he retired from active work, and on the 10th of February 1901 he shot himself in a fit of depression at his home on the Starnberger See, near Munich. In his earlier years he devoted himself to chemistry, both theoretical and applied, publishing papers on the preparation of gold and platinum, numerical relations between the atomic weights of analogous elements, the formation of aventure glass, the manufacture of illuminating gas from wood, the preservation of oil-paintings, &c. The reaction known by his name for the detection of bile acids was published in 1844. In his widely used method for the quantitative determination of carbonic acid, the gaseous mixture is shaken up with baryta or lime water of known strength and the change in alkalinity ascertained by means of oxalic acid. But his name is most familiar in connexion with his work in practical hygiene, as an apostle of good water, fresh air and proper sewage disposal. His attention was drawn to this subject about 1850 by the unhealthy condition of Munich.

Pettetkofer gave very vigorous expression to his views on hygiene and disease in numerous books and papers; he was an editor of the Zeitschrift für Biologie from 1863 to 1882, and of the Archive für Hygiene from 1883 to 1902.

PETTICOAT, an underskirt, as part of a woman's dress. The petticoat, i.e. "petticoat" or small coat, was originally a short garment for the upper part of the body worn under an outer dress; in the Promotriorium parvulorum the Latin equivalent is tunicula. It was both a man's and a woman's garment, and was in the first case worn as a small coat under the doublet, and by women apparently as a kind of chemise. It was, however, early applied to the skirt worn by women hanging from the waist, whether as the principal lower garment or as an underskirt. In the middle of the 17th century the wide breeches with heel and gusset were known as "petticoat breeches," a term also applied to the loose canvas or oilskin overalls worn by fishermen.

PETTIE, JOHN (1839-1893), Scottish painter, was born in Edinburgh on the 17th of March 1839, the son of Alexander and Alison Pettie. In 1852 the family removed to East Linton, Haddingtonshire, and a portrait by the lad of the village carrier and his donkey overcame his father's objections to art as a career for his son. When sixteen he entered the Trustees' Academy in Edinburgh, working under Robert Scott Lauder with W. Q. Orchardson, J. MacWhirter, W. M'tTaggart, Peter Graham, Tom Graham and G. P. Chalmers. His first portrait of the Royal Academy was "A Scene from the Fortunes of Nigel"—one of the many subjects for which he sought inspiration in the novels of Sir Walter Scott—and two portraits in 1858, followed in 1859 by "The Prison Pet." To the Royal Academy in 1860 he sent "The Armourers" and the success of this work and of "What d'ye Lack, Madam?" in the following year, encouraged him to settle in London (1862), where he joined Orchardson. In 1866 he was elected an Associate of the Royal Academy, and in 1874 received full academical honours in succession to Sir Edwin Landseer. His diploma picture was "Jacobites, 1745." Pettie was a hard and rapid worker, and, in his best days, a colourist of a high order and a brilliant executant. In his early days he produced a certain amount of book illustration. His connexion with Good Words began in 1861, and was continued till 1864. With J. MacWhirter he illustrated The Postman's Bag (Strahan, 1862), and Wordsworth's Poetry for the Young (Strahan, 1863). His principal paintings, in addition to those already mentioned, are "Cromwell's Saints" (1862); "The Tric" (1863); "George Fox refusing to take the Oath" (1864); "A Drumhead Court-martial" (1865); "The Arrest for Witchcraft" (1866); "Treason" (1867, now in the Mappin Art Gallery, Sheffield); "Tussle with a Highlander Smuggler" (1868); "The Daily Bottle" (1870); and "The Besiegers of Guernsey," "The Truce" (1873); "Hol! Ho! Old Noll" and "A State Secret" (1874); "A Sword and Dagger Fight" (1872); "The Death Warrant" (1879); "Monmouth and James II." (1882); "The Vigil" (1884, in the Chantrey Collection, National Gallery of British Art); "Challenged" (1885); "The Chieftain's Candlesticks" (1886); "Two Strings to Her Bow" (1887); "The Traitor" and "Sir Charles Wyndham as David Garrick" (1888); and "The Ultimatum" and "Bonnie Prince Charlie" (1892). Pettie died at Hastings on the 21st of February 1893. In 1894 a selection of his work was included in the Winter Exhibition of the Royal Academy. His portrait by himself is in the Tate Gallery.

PETTY, SIR WILLIAM (1623-1687), English statistician and political economist, was born on the 26th of May 1623, was the son of a clothier at Romsey in Hampshire, and received his early education at the grammar school there. About the age of fifteen he went to Caen (Normandy), taking with him a little stock of merchandise, on which he traded, and so maintained his first living. He learnt French, improving himself in Latin and Greek, and studying mathematics and other sciences. On his return to England he seems to have had for a short time a place
in the royal navy. He went abroad again in 1643, and remained for three years in France and the Netherlands, pursuing his studies. In Paris he read Vesalius with Hobbes, who was then preparing his \textit{Tractatus opitius}, and it is said that Petty drew the diagrams for him. In 1647 Petty obtained a patent for the invention of double writing, i.e. a copying machine. In politics he espoused the side of the parliament. His first publication was a letter to Samuel Hartlib in 1648, entitled \textit{Advice for the Advancement of some Particular Parts of Learning}, the object of which was to recommend such a change in education as would give it a more practical character. In the same year he took up his residence at Oxford, where he was made deputy professor of anatomy, and where he gave instruction in that science and in chemistry. In 1649 he obtained the degree of doctor of physic, and was soon after elected a fellow of Brasenose College. He gained some notoriety in 1650 by restoring to life a woman who had been hanged for infanticide. In 1651 he was made professor of anatomy at Oxford, and also became professor of music at Gresham College. In 1652 he went to Ireland, having been appointed physician to the army in that country. In 1654, observing that the admeasurement and division of the lands forfeited in 1641 and granted to the soldiers had been "most inefficiently and absurdly managed," he entered into a contract to execute a fresh survey, which he completed in thirteen months.\footnote{By this he gained £2000, and part of the money he invested profitably in the purchase of soldiers' debentures. He thus became possessed of so large a domain in the county of Kerry that, according to John Aubrey, he could behold from Mt Nacrosh the acres of his own land. He set up iron-works in that neighbourhood, opened lead-mines, and quarries, established a pilchard fishery, and commenced a trade in timber. Besides the office of commissioner of distribution of the lands he had surveyed, he held that of secretary to the lord-lieutenant, Henry Cromwell, and was also during two years clerk of the council. In January 1658 he was elected to Richard Cromwell's parliament as member for West Looe in Cornwall. After the Restoration he returned to England and was favourably received and knighted by Charles II., who "was much pleased with his ingenious discourses," and who, it is said, intended to create him earl of Kilmore. He obtained from the king a new patent constituting him surveyor-general of Ireland. In 1660 he attracted much notice by the success of his invention of a double-bottomed ship, which twice made the passage between Dublin and Holyhead, but was afterwards lost in a violent storm. He was one of the first members of the Royal Society, and sat on its council. He died in London on the 16th of December 1687, and was buried in the church of his native place. His will, a curious and characteristic document, is printed in Chalmers' \textit{Biographical Dictionary}.}

His \textit{Treatise of Taxes and Contributions} contains a clear statement of the doctrine that price depends on the labour necessary for production. Petty is much concerned to discover a fixed unit of value, and he thinks he has found it in the necessary sustenance of a man for a day. He understands the cheapening of goods through the introduction of new industries, and he correctly establishes the notion of "natural and true" rent as the remainder of the produce of land after payment of the cost of production; but he seems to have no idea of the "law of diminishing returns." He has much that is just on the subject of money: he sees that there may be an excess of it as well as a deficiency, and regards the prohibition of its exportation as contrary to sound policy. But he errs in attributing the fall of the rate of interest which takes place in the progress of industry to the increase in the quantity of money. He protested against the fitters imposed on the trade of Ireland, and advocated a union of that country with Great Britain. Whilst the general tendency in his day was to represent England as in a state of progressive decline—an opinion put forward particularly in the tract entitled \textit{Britannia langueo}—Petty declared her resources and prospects to be not inferior to those of France.

A complete list of his works is given in the \textit{Athenae oxfordenses}. The most important are: the \textit{Treatise of Taxes and Contributions} (1662, 1667 and 1668); \textit{Political Arithmetic}, presented in MS. to Charles II., and published at a later date; but, because it was dedicated to France, kept unpublished till 1691, when it was edited by Petty's son Charles; \textit{Quantulumcunque}, or a Tract concerning Money (1682); \textit{A Short Account of the Dublin Bills of Mortality in Sir and the State of that City} (1683); \textit{Essay concerning the Multiplication of Mankind} (1686); \textit{Political Anatomy of Ireland} (1691). Several papers appeared in the \textit{Philosophical Transactions}. See \textit{Economic Writings of Sir William Petty}, ed. C. M. Hill 2 vols (1890).

\textbf{PETTY-OFFICER}, the title in the name of a large number of minor (Fr. petit, small) officers, of less than commissioned or warrant rank—such as the master-at-arms, sailmaker, caulker, armourer, cook, &c. They were originally named, and removable, by the captain.

\textbf{PETUNIA}, in botany, a genus of plants belonging to the natural order Solanacea and containing about 16 species, chiefly South American (southern Brazil and Argentina). The garden forms are derived from the white-flowered \textit{P. noctiflora} and the violet- or purple-flowered \textit{P. violacea}. The varieties of petunia, especially the double forms, make admirable specimens for pot culture.

Named or specially fine varieties are propagated by cuttings taken from the stock plant, which is raised in a frame or a cold frame, and were used in the greenhouse for the same purpose. The shoots were placed in a box of sandy soil in a frame, and when rooted were potted singly and carefully covered. The plants need to be pricked out or potted off as soon as large enough to handle. Good strains of seeds supply plants suitable for bedding; but, as they do not reproduce themselves exactly, any sorts particularly required must be propagated, like the double ones, from cuttings.

\textbf{PETWORTH}, a market town in the Horsham parliamentary division of Sussex, England, 55 m. S.S.W. from London by the London, Brighton & South Coast railway. Pop. (1901), 2503. The church of St Mary is Perpendicular, and contains numerous memorials of members of the Percy family and others. Petworth House, situated in a beautiful park, dates from the 18th century, and contains a magnificent collection of pictures. At Bignor in the neighbourhood are remains of an important and splendidly adorned Roman villa.

The first mention of Petworth (Peartingawyrth, Petorde, Puettorde, Pedewurde, Putevorth, Pytteworth, Petworth) occurs in an act by Earl Wulf, king of Northumbria, to St Peter's Church, about 971. In the time of Edward the Confessor Petworth was an alodial manor held by his queen Edith, and in 1086 Robert Fitz-Tetbald held it of Roger Montgomery, earl of Shrewsbury. It then included a church and a mill, and was rated at nine hides. Through Queen Adela, Petworth came first into the hands of
her steward, Reginald de Wyndsr, and was afterwards given to her brother Josceline, who held it of the honour of Arundel. Josceline married Agnes de Percy and assumed the surname of Percy. The honour and manor of Petworth followed the descent of this family until 1708. In 1377 Henry Percy was created earl of Northumberland. The only daughter of the last earl married Charles, duke of Somerset, in 1682, and Petworth descended through their daughter Catherine to the ears of Egremont. The adopted son of the third earl was created Baron Leconfield in 1382.

PEUTINGER KONRAD (1465-1542), German humanist and antiquarian, was born at Augsburg. In 1497 he was town clerk of his native place, and was on intimate terms with the emperor Maximilian. He was one of the first to publish Roman inscriptions, and his name remains associated with the famous Tabula peutingeriana (see MAP), a map of the military roads of the western Roman Empire, which was discovered by Konrad Celtes, who handed it over to Peutinger for publication. Peutinger also edited the Historia Gothorum of Jordanes, and the Historia gentis Langobardorum of Paulus Diaconus.

The Tabula peutingeriana was first published as a whole by F. de Scheyb (1753); later editions by E. Desjardins (1869-1874) and C. Miller (1888); see also E. Paulus, Erklärung der Peutinger Tafel (1867); and Teuffel-Schwabe, Hist. of Roman Literature (trans., 1897).

PEVENSEY, a village in the Eastbourne parliamentary division of Sussex, England, 65 m. S.S.E. from London by the London, Brighton & South Coast railway. Pop. (1901) 468. The village is a member of the Cinque Ports, but the sea has receded a mile from it in historic times. The outer wall, with solid towers, of the celebrated castle, is of Roman construction, and originally enclosed a complete oval; it is generally considered to have enclosed the strong town of Andreda. Within the fine ruins, principally of the 13th century, but in part Norman, of the castle proper, with a keep and four massive round towers. The church of St Nicholas, close to the castle, shows beautiful Early English work. It has been supposed that Pevensey was the scene of the landing of Caesar in 55 B.C., but the question is disputed.

The name of Pevensey (Faevensel, Pevensel, Pevenes, Pesme) first occurs in a grant of land there by the south Saxon Duke Berthwald to the abbey of St Denis in 795. In later Saxon times, at least by the reign of Edward the Confessor, it was a royal borough and had a harbour and a market. Its early importance was due to its felicible port. It was the landing place of William the Norman on his way to conquer, and was the caput of the rape of Pevensey, which was granted by William to the earl of Mortain and subsequently became the Honour of the Eagle. Some time before the reign of Edward I. the town of Pevensey was made a member of Hastings and shared the liberties of the Cinque Ports, but apart from them it possesses no charter. It was governed by a bailiff and twelve jurors, elected annually, until by an act of 1883 it ceased to exist as a borough. Its seal dates apparently from the reign of Henry III. The gradual decline of Pevensey was complete in the 15th century and was caused by the recession of the sea and consequent loss of the harbour.

PEW (Mfd. Eng. pwce, through O. Fr. pwce, pwé, mod. puy, in the sense of hill, cf. a puyder, to lean against; from Lat. podium, a high place, balcony; Gr. πόδαιος, pedestal, πόδος, foot), a term, in its most usual meaning, for a fixed seat in a church, usually enclosed, slightly raised from the floors, and composed of wood framing, mostly with ornamented ends. Some bench ends are certainly of Decorated character, and some have been considered to be of the Early English period. They are sometimes of plain oak board, $\frac{3}{4}$ to 3 in. thick, chamfered, and with a necking and finial generally called a poppy head; others are plainly panelled with bold cappings; in others the panels are ornamented with tracery or with the linen pattern, and sometimes with roundels or medallions. The pew is enclosed by the enclosures, curtains, &c., known familiarly as "horse-boxes," and common in English parish churches during the 18th and early part of the 19th century, have nearly all been cleared away. The parish church of Whitby, in Yorkshire, is perhaps the best surviving example of an unaltered interior.

The Latin word podium was particularly applied to a balcony or parapet next to the arena in the Roman theatre where the emperor and other distinguished persons sat. According to the PEUTINGER (Glossarium, s.v. podium), it is found in medieval Latin for a bench (subcellium) for the minor canons at a church in Lyons (1433), and also for a kneeling stool in a monastic church. The word "pew" in English was often used for a stall for the minister, for a reading desk, or for a pulpit. The floor space of the nave and transepts of medieval churches was usually open, mats being sometimes provided for kneeling, and if any fixed seats were provided these would be for the patrons of the church or for distinguished people. Some enclosed seats, however, seem to have been reserved for women, as is seen in Piers Plowman, ch. vii. 144. "Among wyves and wodewes..." One enclosed pew, or kneeling stall, is usually attributed to the Premonstratensians, and was the source of the word "pewter." It did not come into general use till the middle of the 15th or beginning of the 16th century (see Gasquet, Parish Life in Medieval England, 1906, pp. 62 and 133). Over the few seats thus allotted dispute arose and attempts were made to appropriate them. Thus the constitutions for the synod of Exeter, drawn up by Bishop Peter Quivell in 1287, forbid any one "to claim any sitting in the church as his own... Whoever first comes to pray, let him take what place he wishes in which to pray."

At common law all seats in a parish church are for the common use of all the parishioners, and every parishioner has a right to a seat without paying for it. The disposition of the seats is in the discretion of the churchwardens acting for the ordinary for the purpose of orderly arrangement (as to the exercise of this discretion see Reynolds v. Monchurch, 1841, 2 M. & R. 354), and this can be exercised in cases where all the seats are free (Ather v. Celerafi, 1887, 18 Q.B.D. 607). The right to a seat does not belong to a non-parishioner. As against the assignment and disposition of seats by the ordinary, acting through the churchwardens, two kinds of appropriation can be set up (a) by the grant of a seat at the instance of the ordinary, and (b) by prescription, based on the presumption of a lost faculty. Such faculties are rarely granted now; they were formerly common; the grant was to a man and his family "so long as they remain inhabitants of a certain house in the parish"; the words "of a certain house" are now usually omitted. The claim to a pew by prescription must be in respect of a house in the parish; the right is subject to the burden of repairing the pew; it is not an easement, nor does the Prescription Act 1832 apply to it (see for the whole subject of a claim by prescription Phillips v. Halliday, 1867, A.C. 238). The letting of pews in parish churches became common in the 16th century, but there are some earlier instances of the use, for example, of the pew of Sir John Wrottesley, in 1345. Ewens, Sir J. Maclean, Trans. Bristol and Gloucester Archaeol. Assoc., vol. xv. 1800-1901. The taking of pew rents in parish churches is illegal (Lord Stowell, in Walter v. Gunner, 1798, 3 H. & C. 817), but under various the Church Building Acts seats may be let and rents charged to pay the salary of the minister, &c.

See A. Heales, History and Law of Church Seats and Pews (1872); Philimore, Eccles. Law (1896), ii. 1424 seq.

PEWTER, a general name used to denote a number of alloys of various metals in diverse proportions, the sole common feature of which lies in the fact that tin is always the chief constituent. The etymology of the word is doubtful, but it is probably an abbreviation of spelcher, which was adopted with more or less local alteration by the continental European nations, who at an early period were eager purchasers of the ware, becoming peuzier in Dutch, pezeur, peuzarte or piuzarte in French, pelvo in Italian and pelvre in Spanish. Roman pewter, the oldest known, which has been disinterred at various places in England and elsewhere, was composed of tin and lead alone, for the occasional traces of iron are believed to be accidental, in proportions which, though varying considerably, group themselves around two definite formulae, one containing 51-5 parts of tin to 27-8 of lead, the other 78-2 of tin to 21-7 of lead, or one libra of tin to 43 and 3 unciae of lead respectively. On the European continent in the middle ages, some ten centuries later than the supposed date of the Roman pewter found in Britain, when we first get definite records of the composition of pewter, lead remained the chief, if not the only secondary ingredient. In 1437 the pewterers of Montpelier added 4 parts of lead to 66 of tin,
when making dishes and porringer 10 parts of lead to 90 of tin for salt-cellars and ewers; those of Limoges used 4 parts of lead to 100 of tin; at Nuremberg in 1576 it was ordained that not more than 1 lb of lead should be mixed with every 10 lb of tin; in France during the 18th century a limit of 15% of lead was imposed, while at the present time 16-5% with a margin of 1-5 for errors was regarded as safe for the storage of wine and consequently legal.

In England the earliest known ordinances for the regulation of the craft were drawn up in 1348 and received the approval of the mayor and aldermen. From them we learn that for rounded vessels lead might be mixed with the tin in the proportion of 26 lb to each hundredweight, though this quantity appears to have been found excessive, since in 1557 a pewterer was punished because his alloy contained more than 16 lb to the hundredweight, unless this be a clerical error in the contemporary records of the Pewterers' Company. Articles made of this material were to be known as "vessels of tin for ever" but the alloy soon came to be known as "ley." Another formula, however, authorized in the same document, would appear to have been at that time an exclusively English secret, to which was presumably due the universal recognition of the superiority of the island wares which is so notable a fact in the history of pewter. It was known as "fyne peater" and used for dishes, saucers, platters, chargers, and for all "things that they make square," such as cruets, chisarmatories, &c., which owing either to the rough usage they would be submitted to, or to the sharpness of their angles, called for greater toughness in the material. The recipe for this alloy as originally propounded was as much brass to the tin "as it wol receve of his nature," but the lack of precision in this perhaps rendered it difficult to distinguish accidental variations from deliberate adulteration, and in 1424-1425 it was resolved that 26 lb of brass must be mixed with every hundredweight of tin. The penalties for infringement of the rules were severe and frequently enforced, but in spite of them alterations and improvements crept in. The chief and perhaps the earliest of these was the addition of a certain proportion of bismuth, or as it was then called "tin glass." When this was first used is not recorded, but by 1561 it was accepted as a matter of course; in 1630 a maker "was found in fault for not sufficiently tempering his metal with tin glass"; and in 1653 it was ordered that 3 lb weight of tin glass at least must be mixed with every 1000 lb of tin. Antimony was subsequently introduced—though there is no mention of it in the records of the Pewters' Company—sometimes alone (1589) and sometimes in conjunction with copper (1602, 1625, 1626, 1633), or to 83 of tin, sometimes with other metals as in hard metal (96 parts of tin, 8 of antimony and 2 of copper), a mixture very closely resembling that still used under the name of "Britannia metal," and in plate pewter (100 parts of tin, 8 of antimony, 4 of copper and 4 of bismuth). The wares were originally fashioned in two ways, by hammering or by casting, and the workers in each were strictly differentiated, the former, who worked in fine pewter, being known as Sadware men, the latter who used "ley" as Hollow-ware men. A third class, known as Trillers, from the alloy they were limited to, probably at first only manufactured such small articles of domestic use or ornament as did not definitely fall under either of the other headings, and authorized lists of wares, drawn up by a committee of Trillers in 1612, it is clear that the barrier between them and the Hollow-ware men had been largely broken down. Another method of working pewter which seems to have been introduced later, and never followed to any great extent, was spinning, by which the vessel was shaped in a mould on a wheel by the mere pressure of a blunt tool, the softness of the metal allowing of its flowing sufficiently for this purpose.

Pewter first appears in history in 1074, when a synod at Rouen permitted its use as a substitute for gold or silver in church vessels, a concession accepted also at Winchester two years later, again withdrawn in 1175, but once more tacitly adopted some twenty years after. The records of its domestic use commence with the caldrons employed for boiling the meat at the coronation of Edward I. in 1274, though we gather that the trade was even then flourishing in Paris and Bruges, whence during the following century it extended to Augsburg, Nuremberg, Poitiers, Mons and other continental centres. Confined at first to the more wealthy classes, we can trace as time goes on its extension lower and lower in the social scale, until at the end of the 17th century its use was almost universal. Thenceforward its vogue steadily declined. The growing cheapness of glass and chinaware and the invention of more showy metals brought upon it by degrees the fatality of its own beauty until with very few exceptions its manufacture entirely ceased.

Artistically, pewter was at its best when its makers were least conscious of the art revealed in it, thinking more of the durability and appropriateness to purpose of their wares than of their decorative qualities. Though intentionally ornamental vessels may be found earlier, it was not until the 18th century that the pewterers set themselves to slavishly copying the designs and methods of the silversmiths, whether suitable to their material or not, and thereby undoubtedly hastened their own downfall.

Of recent years pewter has taken its place among the articles sought after by collectors, and its cost has so materiality and rapidly increased that the manufacture of vessels, guaranteed of course genuinely antique, bids fair to become once more a paying industry. Unfortunately the various enactments compelling each maker to stamp his ware with a definite touchmark seem at all times to have been very generally evaded or ignored, and experience alone is therefore the only safe guide to distinguishing new from old.

PÉZENAS—PFAFF

PÉZENAS, a town of southern France, in the department of Hérault 33 m. W.S.W. of Montpellier on the southern railway. Pop. (1906), 6432. The commerce in cognac, spirits and wines is so important that the prices current for these at the weekly sales are registered throughout the wine marts of France and Europe. There is a handsome monument to Molière, who lived at Pézenas several years and produced his first plays there in 1655 and 1656. It was his gateway to Berlin (15th century) and old mansion of the 15th and 16th centuries are of interest.

Pézenas (Piscenae) was founded by the Gauls. In the 10th century it became the capital of a countship subsequently held by important families including those of Montmorency, Condé and Conti. In the 17th century the town was on several occasions the meeting place of the estates of Languedoc.

PFAFF, JOHANN FRIEDRICH (1765-1825), German mathematician, was born on the 22nd of December 1765 at Stuttgart. He received his early education at the Carlsruhe, where he met F. Schiller, his lifelong friend. His mathematical capacity was early noticed; he pursued his studies at Göttingen under Abraham Bottger (1719-1799), and in 1787 he went to Berlin and studied practical astronomy under J. E. Bode. In 1788 Pfaff became professor of mathematics in Helmstedt, and so continued until that university was abolished in 1810. From that time till his death on the 21st of April 1825 he held the chair of mathematics at Halle. Pfaff's researches bore chiefly on the theory of series, to which he applied the methods of the so-called combinatorial school of German mathematicians, and on the solution of differential equations. His two principal works are Disquisitiones analyticae maxime ad calculus integrationem et doctrinam serierum pertinentes (4to., vol. i, Helmstedt, 1797) and "Methodus generalis, aequationes differentiarum particularum, nee aequationes differentiales vulgares, ut aequationes integranda, in quattuorque variables, complete integrandae" in Abh. d. Berl. Acad. (1814-1815). The former work contains Pfaff's discussion
of a certain differential equation which generally bears his name, but which had originally been treated in a less complete manner by L. Euler (see Differential Equations). The latter work contains an important addition to the theory of partial differential equations as it had been left by J. L. Lagrange.

His brother, Johann Wilhelm Andreas PfaFF (1776–1853), was professor of pure and applied mathematics successively at Dorpat, Nuremberg, Würzburg and Erlangen. Another brother, Christian Heinrich PfaFF (1773–1852), graduated in medicine at Stuttgart in 1793, and from 1801 till his death was professor of medicine, physics and chemistry at the university of Kiel.

Pfalz, a town of Germany, in the imperial province of Alsace–Lorraine, lies high on the Rhine river, between the Vosges, 25 m. N.W. of Strassburg by rail. Pop. (1905), 37,16. It contains an Evangelical and a Roman Catholic church, a synagogue and a teachers’ seminary. Its industries include the manufacture of gloves, straw hats and liqueurs, and also quarrying.

The principality of Pfalz, of which this town was the capital, originally a part of Luxembourg, afterwards belonged in turn to the bishop of Metz, the bishop of Strassburg and the duke of Lorraine, and passed into the possession of France in 1661. The town was of importance as commanding the passes of the Vosges, and was strongly fortified by Vauban in 1680. The town and the two states of Alsace and Lorraine, the Germans for four months in 1870, but they were taken on the 12th of December of that year. They have since been razed.

Pfeiffer, Franz (1815–1868), German scholar, was born at Bettlach near Solure on the 27th of February 1815. After studying at the university of Munich he went to Stuttgart, where in 1846 he became librarian to the royal library. In 1856 Pfeiffer founded the Germania, a quarterly periodical devoted to German antiquarian research. In 1857, having established his name as one of the foremost authorities on German medieval literature and philology, he was appointed professor of these subjects at the university of Vienna; and in 1860 he was made a member of the Imperial Academy of Sciences. He died at Vienna on the 29th of May 1868.

Pfeiffer, Ida Lauba (1792–1858), Austrian traveller, daughter of a merchant named Reyer, was born at Vienna on the 14th of October 1797. In 1820 she married Dr. Pfeiffer, a lawyer of Lemberg, who subsequently incurred official persecution and was reduced to poverty. In her later life Mme. Pfeiffer devoted her limited means to travel. In 1842 she visited Palestine and Egypt, and published an account of her journey in Reise einer Wienerin in das Heilige Land (Vienna, 1843). In 1845 she set out to Scandinavia and Iceland, describing her tour in two volumes, Reise nach dem skandinavischen Norden und der Island (Paris, 1846). In 1848 she started on a journey round the world, visiting Brazil, Chile and other countries of South America, Tahiti, China, India, Persia, Asia Minor and Greece, and reaching home in 1848. The results were published in Eine Frauenfahrt um die Welt (Vienna, 1850). In 1851 she went to England and thence to South Africa, intending to penetrate into the interior; this proved impracticable, but she proceeded to the Malay Archipelago, spending eighteen months in the Sunda Islands and the Moluccas. After a visit to Australia, Madame Pfeiffer proceeded to California, Oregon, Peru, Ecuador, New Granada, the Missions Territory, and north again to the Great Lakes, reaching home in 1854. Her narrative, Meine zweite Weltreise, was published at Vienna in 1856. In May of the same year she set out to explore Madagascar, where at first she was cordially received by the queen. But she unwittingly allowed herself to be involved in a plot to overthrow the government, and was expelled the country. She died at Vienna on the 27th of October 1858.

The Reise nach Madagascar was issued in 1861 (Vienna), with a biography by her son.

Pfleiderer, Otto (1839–1908), German Protestant theologian, was born at Stetten near Cannstatt in Württemberg on the 1st of September 1839. From 1857 to 1861 he studied at Tübingen under F. C. Baur; and afterwards in England and Scotland. He then entered the ministry, became rector at Tübingen, and for short time held a pastorate at Heilbronn (1860). In 1870 he became chief pastor and superintendent at Jena and soon afterwards professor ordinarius of theology, but in 1875 he was called to the chair of systematic theology at Berlin, having made his name by a series of articles on New Testament criticism and Johannine and Pauline theology, which appeared in Adolf Hilgenfeld’s Zeitschrift für wissenschaftliche Theologie, and by his Der Paulinismus, published in 1873 (2nd ed., 1890; Eng. trans., Paulinism: a Contribution to the History of Primitive Christian Theology, 2 vols., 1873, &c.). Das Urchristentum, seine Schriften und Lehren, in geschichtlichem Zusammenhang beschrieben was published in 1878 and considerably enlarged for a second edition in 1906 (Eng. trans., 1906). In 1890 appeared The Development of Theology since Kant, and Its Progress in Great Britain since 1825, which was written for publication in England. A more elaborate work was his Religionsphilosophie auf geschichtlichem Grundlage (1878; 2nd ed., enlarged, 1883–1884; Eng. trans., from 2nd German ed., The Philosophy of Religion on the Basis of its History, 4 vols., 1886–1888). "The Influence of the Apostle Paul on the Development of Christianity" was the title of a course of Hibbert Lectures given in London in 1885. In 1894 he delivered the Gifford Lectures at Edinburgh, the subject being "The Philosophy and Development of Religion." His later publications included: The Early Christian Conception of Christ (1903), Die Entstehung des Christentums (1905; Eng. trans., 1906), Religion und Religionen (1906; Eng. trans., 1907), and Die Entwickelung des Christentums (1907). He died on the 18th of July 1908, at Gross Lichterfelde, near Berlin. In New Testament criticism Pfleiderer belonged to the critical school which grew out of the impulse given by F. C. Baur. But, like other modern German theologians, he showed a greater disposition to compromise. All his work shows a judicial tone of mind, and is remarkable for the charm of its style.

Pfleiderer’s younger brother Edmund (1842–1902) distinguished himself both in philosophy and theology. He too entered the ministry (1864) and during the Franco-German War served as army chaplain, an experience described in his Erlebnisse eines Feldgeistlichen (1890). He was afterwards appointed professor ordinarius of philosophy at Kiel (1873), and in 1878 he was elected to the philosophical chair at Tübingen. He published works on Leibnitz, empiricism and scepticism in Hume’s philosophy, modern pessimism, Kantic criticism, English philosophy, Herachists of Ephesus and many other subjects.

Pforta, or Schulpforta, formerly a Cistercian monastery dating from 1149, and now a celebrated German public school. It is in the Prussian province of Saxony, on the Saale, 2 m. S.W. of Naumburg. The remains of the monastery include the 13th century Gothic church, recently restored, the Romanesque chapel (12th century) and other buildings now used as dormitories, lecture rooms, &c. There is also the Fürstenhaus, built in 1573. Schulpforta was one of the three Fürstenschulen founded in 1543 by Maurice duke, and later elector, of Saxony, the two others being at Grimma and at Meissen. The property of the dissolved monastery provided a good revenue for the new educational foundation, which now amounts to about £15,000 a year. Free education is provided for 140 boys, the total number of pupils being 185. After being in the possession of Saxony, Pfirta passed to Prussia in 1815, and since this date the school has been entirely reorganized.
PFORZHEIM—PHAEDRUS

PFORZHEIM, a town of Germany, in the grand duchy of Baden, at the confluence of the Nagold and the Enz, on the northern margin of the Black Forest, 19 m. S.E. of Karlsruhe by rail, and at the junction of lines to Wildbad and Ettingen. Pop. (1893), 33,345; (1905), 59,395, most of whom are Protestants. Its most interesting buildings are the old palace of the margraves of Baden, and the Schlosskirche, the latter an edifice of the 12th–13th centuries, containing the tombs and monuments of the margraves. Pforsheim is the chief centre in Germany for the manufacture of gold and silver ornaments and jewelry, an industry which gives employment to about 22,000 hands, besides which there are iron and copper works, and manufactures of chemicals, paper, leather, machinery, &c. A brisk trade is maintained in timber, cattle and agricultural produce. Pforsheim (Porchia Hercyniae) is of Roman origin. From about 1300 to 1565 it was the seat of the margraves of Baden. It was taken by the troops of the Catholic League in 1624, and was destroyed by the French in 1689. The story of the 400 citizens of Pforsheim who sacrificed themselves for their prince after the battle of Wimpfen in May 1622 has been relegated by modern historical research to the domain of legend.

DIE 400 Pforzheimer (1879); Brombacher, Der Tod der 400 Pforzheimer (Pforzheim, 1886); Stolz, Geschichte der Stadt Pforzheim (Pforzheim, 1901).

PHAEDO, Greek philosopher, founder of the Elian school, was a native of Elis, born in the last years of the 5th century B.C. In the war of 401–400 between Sparta and Elis he was taken prisoner and became a slave in Athens, where his beauty brought him notoriety. He became a pupil of Socrates, who conceived a warm affection for him. It appears that he was intimate with Cebes and Plato, and he gave his name to one of Plato's dialogues. Athenaeus relates, however, that he resolutely declined responsibility for any of the views with which Plato credits him, and that the relations between him and Plato were then reversed of friendly. According to Cicero, he also wrote a dialogue called Phaedo. Shortly after the death of Socrates Phaedo returned to Elis, where his disciples included Archiphius, Moschus and Pleistianus, who succeeded him. Subsequently Menedemus and Asclepiades transferred the school to Eretria, where it was known as the Eretrian school and is frequently identified (e.g. by Cicero) with the Megarians. The doctrines of Phaedo are not known, nor is it possible to infer them from the Platonic dialogue. His writings, none of which are preserved, were in the form of dialogues. As to their authenticity nothing is known, in spite of an attempt at selection by Panetius (Diog. Laërt. ii. 64), who maintains that the Zephyrus and the Simon are genuine. Seneca has preserved one of his dialogues (Ep. 90, 42), namely that one method of acquiring virtue is to frequent the society of good men.

See Wilamowitz, Hermes, xiv. 189 seq.

PHAEDRA, in Greek legend, daughter of Minos and Pasiphaé. With her sister Ariadne she was carried off by Theseus to Athens, and became his wife. On the way to Eleusis she met Hippolytus, son of Theseus by a former wife (Hippolyte, queen of the Amazons, or her sister Antiope), and fell in love with him. Finding her advances rejected, she hung herself, leaving behind a letter in which she accused Hippolytus of having made dishonourable proposals to her. The same story, in the main, is told of Bellerophon and Antea. It formed the subject of tragedies by Sophocles, Euripides (two, one of which is extant), Seneca and Racine.

PHAEDRUS, Roman fabulist, was by birth a Macedonian and lived in the reigns of Augustus, Tiburius, Gaius and Claudius. According to his own statement (prologue to book iii.), not perhaps to be taken too literally, he was born on the Pirican Mountain, but he seems to have been brought at an early age to Italy, for he mentions that he read a verse of Ennius as a boy at school. According to the heading of the chief MS. he was a slave and was freed by Augustus. He incurred the hatred of Sejanus, the powerful minister of Tiberius, by some supposed libel on Bellerophon. He was brought to trial and punished. We learn this from the prologue to the third book, which is dedicated to Eutychus, who has been identified with the famous charioteer and favourite of Gaius. The fourth book is dedicated to Particulo, who seems to have dabbled in literature. The dates of their publication are unknown, but Seneca, writing between A.D. 41 and 43 (Consol. ad Polyb. 27), knows nothing of Phaedrus, and it is probable that he had published nothing then. His work shows little or no originality; he simply versified in iambic trimeters the fables current in his day under the name of "Aesop," interspersing them with anecdotes drawn from daily life, history and legend. The chief sources of his material were the fabulae of Hares and the fabulae of Bellerophon. Phaedrus is a cunning imitator of old-fashioned storytelling literature, with a businesslike directness and simplicity; his language is terse and clear, but thoroughly prosaic, though it occasionally attains a dignity bordering on eloquence. His Latin is correct, and, except for an excessive and peculiar use of abstract words, shows hardly anything that might not have been written in the Augustan age. From a literary point of view Phaedrus is inferior to Battrus, and to his own imitator, La Fontaine; he lacks the quiet picturesque and pathos of the former, and the exuberant vivacity and humour of the latter. Though he frequently refers to the envy and destruction which pursued him, Phaedrus seems to have attracted little attention in antiquity. He is mentioned by Martial (vi. 19, 5), who imitated from his verses, and by Avianus. Prudentius must have read him, for he imitates one of his lines (Prud. Cath. vii. 115; cf. Phaedrus, iv. 6, 10).

The first edition of the five books of Phaedrus was published in 1596 from a manuscript now in the possession of the Bibliothèque nationale at Paris. The first edition of the five books, with the prologue to book i., was published in 1641 by Jannell (1641). Both editions were superseded by the discovery of a much better preserved MS. of Perott at the Vatican, published by Angelo Mai in 1851. For some time the authenticity of these new fables was disputed, but they are now generally accepted, and with justice, as genuine fables of Phaedrus. They do not form a sixth book, for we know from Avianus that Phaedrus wrote five books only, but it is impossible to assign them to their original place. The first five books have been translated into English by Lock (1660), by Selden (1707) and by W. Dods (1823). In the middle ages Phaedrus exercised a considerable influence through the prose versions of his fables which were current, though his own works and even his name were forgotten. Of these prose versions the oldest existing seems to be that known as the "Anonymous Nilanti," so called because first edited by Nilant at Leiden in 1709 from a MS. of the 13th century. It approaches the text of Phaedus so closely that it may be called a prototypical seventy-four fables, of which it contains thirty are derived from lost fables of Phaedrus. But the largest and most influential of the prose versions of Phaedrus is that which bears the name of Romanus. It contains thirty-four fables, is as old as the third century, and seems to have been based on a still earlier prose version, which, under the name of "Aesop," and addressed to one Rufus, may have been written in the Carolingian period or even earlier. Another version of Romanus in the English version was published in the Weissenburg (now Wolfenbüttel) MS. is based on the same version as Romanus. These three prose versions contain in all one hundred distinct fables, of which fifty-six are derived from the existing and the remaining forty-four presumably from lost fables of Phaedrus. Some scholars, as Burmann, Dressler and L. Müller, have tried to restore these lost fables by versifying the prose versions.

The collection bearing the name of Romanus became the source from which the fables of the La Fontaine were drawn, during the 17th century. All the collections of Latin fables in prose and verse were wholly or partially drawn. A 12th-century version of the first three books of Romanus in elegiac verse enjoyed a wide popularity, even into the 17th century, and was translated by Marie de France. About 1200 a collection of fables in Latin prose, based partly on Romanus, was made by the Cistercian monk Odo of Sherrington; they have a strong medieval and clerical tinge. In 1570 Gerard of Minden wrote a poetical version of Romanus in the German.
medieval versions of Phaedrus and their derivatives see L. Roth, in *Philologus*, i. 523 seq.; E. Grosse, in *Jahrh. f. class. Philol.*, cv. (1872); and especially the learned work of Hervieux, *Les Fabulistes latins depuis le solde d'Auguste jusqu'a la fin du moyen âge* (Paris, 1884), who gives the Latin texts of all the medieval imitators (direct and indirect) of Phaedrus, some of them being published for the first time.

**PHAER—PHAGOCYTOSIS**

Avic: *Phaer* (or *Phayer*), **Thomas** (1507-1560), English translator of Virgil, was educated at Oxford and at Lincoln's Inn. He published in 1535 *Natura brevium*, and in 1543 *Newe Bokes of Presidents*. He says on the title-page of his version of the *Aeneid* that he was "solicitor to the king and queen's majesties, attending their honourable council in the marches of Wales." He settled at Kilgarran in Pembrokeshire, and combined his studies with the practice of medicine. He wrote several medical works, and was admitted M.D. of Oxford in 1559. Phaer's translation, which was in rhyme fourteen-syllabled lines, was greatly admired by his contemporaries, and he 1584. Phaer's translation, which was in rhyme fourteen-syllabled lines, was greatly admired by his contemporaries, and he was even credited as the first to attempt a complete version, the earlier renderings of Surrey and Gawden Douglas being fragmentary although of greater poetic value.

**PHAETHON** (Gr. *φαέθων*, shining, radiant), in Greek mythology, the son of Helios the sun-god, and the nymph Clymene. He persuaded his father to let him drive the chariot of the sun across the sky, but he lost control of the horses, and driving too near the earth scorched it. To save the world from utter destruction Zeus killed Phaethon with a thunderbolt. He fell to earth at the mouth of the Eridanus, a river of northern Europe (identified in later times with the Po), on the banks of which his weeping sisters, the Heliadès, were transformed into poplars and their tears into amber. This part of the legend points to the mouth of the Oder or Vistula, where amber abounds. Phaethon was the subject of a drama of the same name by Euripides, of which some fragments remain, and of a lost tragedy of Aeschylus (*Hexitades*); the story is most fully told in the *Metamorphoses of Ovid* (i. 720-ii. 366 and Nonnus, *Dionysiosica*, xxxviii). Phaethon has been identified with the sun himself and with the morning star (Phosphorus). In the former case the legend is supposed to represent the sun sinking in the west in a blaze of light. His identification with the morning star is supported by Hyginus (Astron. ii. 42), where it is stated that the morning (and evening) star was the son of Cybele and the sun god. His father also appears in a passage of the *Theog. to Hesiod* (984-986). The fall of Phaethon is a favourite subject, especially on sarcophagus reliefs, as indicating the transitoriness of human life.

**PHAGOCYTOSIS** (Gr. *φαγεται*, to eat, devour, and κορόν, cell). Many cells of the body possess the property of engulfing particles, a character to be associated with their power of performing amoeboid movement. This property is termed phagocytosis. Primarily this phagocytic power was simply the means by which the cell took within its cell body food particles which were ultimately digested and assimilated. In the higher organisms, however, this property has been developed for different purposes, and in pathology at the present day a meaning wider than that above given is often included in the term. The particle having been taken into the cell, one of three things may happen. (1) The particle may consist of digestible material, in which case the cell secretes a digestive fluid, a food vacuole is formed, the particle is gradually dissolved by the secretion and the products absorbed into the cell substance. (2) The particle may be indigestible, in which case it is retained within the cell body for a time and ultimately discharged. The particle engulfed may comprise almost any material, but if it is to serve as a food it must be of animal or vegetable origin. At the time of ingestion it may be dead or living. In the case in which it is living the organism is first killed and then digested, or (3) the organism may prove resistant, in which case it may multiply and finally destroy the cell, when a number of organisms are set free. This is one of the means by which, in the higher organisms, a local infection may become distributed through the organism. The digestion effected within a cell is fermentative in character. Thus a proteolytic ferment has been prepared from the bodies of amoebae, the ferment possessing fairly active properties both in acid, neutral or alkaline media, but especially in the latter.

In studying the process of phagocytosis generally much information may be gained as to its general characters by the study of the processes of intracellular digestion in the simpler Invertebrates, a study largely extended by Metchnikoff and his co-workers in the elaboration of Metchnikoff's view of the nature of immunity. Thus, to take an instance from the sponges. Food substances, in the form of minute organisms, which have penetrated the pores of the sponge are seized by the ciliated or amoeboid cells lining those spaces, and are then killed and digested. In this case also the process of digestion is proved to be fermentative. It is readily understandable that we should find such cells on the external surface of an organism or on the surface lining the alimentary tract, particularly in the latter position. But in addition there are many cells within the body in which phagocytic power is retained and markedly developed. Such cells may be fixed or wandering cells. They are employed for removing foreign material or debris which may occur within a tissue. For instance, as the result of an injury, inflammatory process, &c., cells and other structures of a tissue may be destroyed. One of the processes of repair consists in the removal of the resulting debris, which is effected by phagocytes. A similar process is seen with red blood corpuscles which may have escaped into a tissue through rupture of capillaries. Foreign particles accidentally gaining admission to a tissue are in many cases removed in a similar manner, e.g., soot particles which have passed through the respiratory surface are then largely removed by phagocytes and carried to the bronchial lymphatic glands. Very commonly living organisms effect an entrance through wound surfaces, the alimentary surface, &c., and one of the processes employed for their destruction and removal is that of phagocytosis.

As an illustration of the removal of foreign red blood corpuscles we may take the experiments of Metchnikoff in which a small drop of defibrinated blood of the goose was injected under the skin of a snail. The corpuscles quickly spread through the haemolymph of the snail, but whether they were digested or not the snail did not show any apparent effects in them. At the end of several hours examination shows that the leucocytes of the snail have engulfed a large number of the red corpuscles. The following day intact corpuscles can still be found in the haemolymph, but the major number have already been devoured by the leucocytes. When taken up by a phagocyte the red corpuscle becomes round and its wall permeable. A vacuole is formed around the corpuscle, in which dissolved haemoglobin can be seen; a part of this haemoglobin also passes into the nucleus of the red corpuscle, proving that it too has been profoundly altered. Many of the nuclei are discharged. After some time the only parts of the corpuscle remaining are pieces of the nucleus and the peripheral layer of the corpuscle. Frequently the phagocytes, after having devoured one or several red corpuscles, themselves become a prey to their fellows. Analogous changes are observed in the tissues of a mammal when blood which has been extravasated is being removed, e.g. after a bruise. The first effect of the haemorrhage is an exudative inflammation, during which leucocytes arrive in large numbers and engulf the corpuscles. In the process of digestion which follows the haemoglobin is altered and new pigments formed from it. In mammals this pigment is dark red or brownish, in the pigeon it is green. Finally the corpuscles are completely digested. Analogous phenomena may be observed.
in connexion with the removal of cell débris resulting from any injury. Numbers of phagocytes may be found at work in this direction, for instance in the pus formed within an aseptic abscess. Hence we may regard the phagocytes as acting as the scavengers of the tissues.

In the instances we have been dealing with the phagocytes are chiefly of the class of wandering cells and are brought to the seat of their activity by the blood. In examining any tissue where the process is going on it is seen that the phagocytes have accumulated there in large numbers. They have been attracted to the damaged area. The mechanism which effects this attraction is a chemical one—chemotaxis. At the seat of the change chemical substances are produced which act upon the phagocytes, causing them to migrate towards the source—positive chemotaxis. Apparently the material dissolving from cell débris can act in this manner. Thus if a capillary tube filled with a tissue extract be inserted under the skin of an animal, within a short time it will be found to be surrounded with numbers of leucocytes, which may also have encroached into the tube itself. As in other instances of chemotaxis the same chemical stimulus in a higher concentration may repel the cells—negative chemotaxis. Instances of this are especially frequent in relation to micro-organisms and phagocytes, to which we may now turn.

That phagocytes can paralyse, kill and digest many micro-organisms is the main fact in Metchnikoff's theory of the nature of immunity. The reaction may be readily studied by injecting a small quantity of a fluid culture of some mildly pathogenic organism into the peritoneal cavity of an animal, and in the course of an hour or so examining a smear from the surface of the omentum, when an abundance of phagocytes enclosing the organism in different stages of digestion will be found. Or we may adopt Leishman's method, in which a few drops of human blood are diluted with saline solution and centrifuged. The layer of white corpuscles is pipetted off, suspended in serum, and a minute drop of a suspension of a pathogenic organism is added. The preparation is then incubated at 37° C. for a quarter of an hour. Upon examining a drop of this mixture a number of bacteria are found within the phagocytes. Thus this attack and destruction of bacteria by phagocytes may take place within the body or by cells removed from the body. Whether or no a phagocyte can engulf bacteria is dependent upon a number of factors—partly specific properties of the phagocyte, partly factors varying with the constitution of the body serum. Thus Wright and Douglas, employing Leishman's method, have proved that leucocytes do not take up bacteria freely unless the serum in which they are suspended contain opsonins. They found, for example, that leucocytes taken from a patient suffering from a pyococci infection if suspended in normal human serum take up the cocci abundantly, whereas if the same leucocytes are suspended under similar conditions in the patient's own serum the reaction may be almost absent. Further, leucocytes taken from a normal individual and suspended in the patient's serum are practically inactive, while the same phagocytes in normal serum are very active. Exactly how the substance in the serum acts is undecided, but it has been proved that there are in serum substances which become fixed to bacteria and which render them an easier prey to the phagocytes. This specific opsonin is used up when the bacteria are added to the serum, so that if the bacteria are subsequently removed the serum is no longer active. There is evidence too that there is a multiplicity of opsonins. As to the origin of the opsonins we have no certain evidence. It is suggested that they are a secretion from the leucocytes themselves and that it is an evidence of another and preliminary mode of attack possessed by the leucocyte, viz, the discharge of a secretion from the cell which is to damage or paralyse the bacterium and thus enable the phagocyte to engulf it.

The mechanism of destruction of a bacterium once it has been taken up by a phagocyte is probably, just as in the instance of dead cellular material, one of intracellular digestion. The bacterium before being engulfed is probably inert in most instances, though it may yet prove too strong for the phagocyte. The next stage we can trace is the formation of a vacuole around the organism, or, if the latter be large, around a part of the organism, and the part thus surrounded quickly shows signs of destruction. For instance, its staining reactions become weaker. When a part only of the organism is surrounded by a vacuole the part thus surrounded soon ceases to stain, while the remaining part stains normally, and we thus have a marked contrast evidencing the two stages.

In the next place we must ask which are the cells possessing phagocytic powers? Leaving apart the cells lining the alimentary tract (because we know practically nothing of their power in this respect) a number of free cells possess amoeboid properties as well as also a number of fixed cells. These latter are attached to certain spots of a tissue, but are capable of throwing out processes which can seize upon particles of foreign matter or even upon certain elements of the same organism. Of this category Metchnikoff distinguishes the nerve cells, the large cells of the spleen pulp and of lymph glands, certain endothelial cells, the neurogli cells, and perhaps certain cells of connective tissues. All these elements can under certain conditions act as phagocytes, and with the exception of the nerve cells all are of mesoblastic origin. Those of greater importance on account of their greater activity in this respect are the large splenic and lymph cells, the neurogli cells and certain endothelial cells. With regard to the wandering cells Metchnikoff considers that some are certainly non-phagocytic, for instance the lymphocytes. According to Metchnikoff it is only when these cells become older and have developed a nucleus rich in chromatin and an abundant cell body that these cells develop phagocytic properties. This is the large hyaline leucocyte. The polymorphonuclear and the eosinophil leucocyte are both phagocytes. Metchnikoff therefore divides the phagocytes into two classes—the microphages, comprising the polymorphonuclear and the eosinophil cell, and the macrophages, containing the large hyaline cell, the cell of the splenic pulp, the endothelial cell and the neurogli cell. From further observation of these cells he concludes that the microphages are chiefly concerned in opposing the micro-organisms of acute infections, whereas the macrophages are chiefly concerned in combating chronic infections. It is the macrophage also which is concerned in removing cell débris, e.g. red corpuscles from a haemorrhage or the red corpuscles of another animal which may have been introduced experimentally.

Metchnikoff and his co-workers have shown that the two principal groups of leucocytes are generally spread throughout the vertebrates. Thus instances of each kind are found even in the lamprey, though here their staining properties are feebler; also among amphibia. They show that small differences from the usual cells of mammals are found in the alligator. (T. G. Bw.)

PHALANGER, a book-name applied to the more typical representatives of the group of diprotodont marsupial mammals, including the cuscuses of the Moluccas and Celebes, and the so-called opossums of Australia, and thus collectively the whole family Phalangeridae. (See Marsupialia.)

Phalangers generally are small or medium-sized woolly-coated marsupials, with long, powerful, and often prehensile tails, large claws, and opposable nailless first hind toes. They seem in the day to be dull and sleepy, but are alert at night. They live mostly upon fruits, leaves and blossoms, although a few feed habitually upon insects, and all relish, in confinement, an occasional bird or other small animal. Several possess flying-membranes stretched between their fore and hind limbs, by the help of which they can make long and sustained leaps through the air, like flying-squirrels; but the possession of these flying-membranes does not seem to be any indication of special affinity, the characters of the skull and teeth sharply dividing the flying forms and uniting them with other species of the non-flying groups. The skull (see fig. 1) is, as a rule, broad and flattened, with the posterior part swollen out laterally owing to the numerous air-cells situated in the substance of the squamosal bones. The dental formula is very variable, especially as regards the premolars, of which some at least in each genus are reduced to functionless rudiments, and may even vary in number on the two sides of the jaw of the same individual. The incisors are
always \( \frac{1}{3} \), the lower one very large and inclined forwards, and the canins normally \( \frac{1}{4} \), of which the inferior is always minute, and in one genus generally absent. The molars number either \( \frac{1}{3} \) or \( \frac{3}{2} \). All the species here discussed are included in the sub-family Phalangerinae, of which the distinctive features, as well as those of the family Phalangeridae, are referred to under Marsupialia.

The most generalized representatives of the group appear to be the ring-tailed phalangers, constituting the genus Pseudechurus, which is common to Australia, Tasmania and New Guinea, and includes at least half a score of species. The dentition is generally \( i. \frac{1}{3} \), \( c. 2 \), \( \frac{2}{m} \), or \( \frac{3}{4} \), but one upper incisor and the canine may be wanting. The crowns of the molars show a crescentic structure, but they are said to retain the three primitive cusps, which are fused in the other genera. The prehensile tail has its tip naked for a short distance, and the whole of the terminal third and the under surface of the remainder short-haired, the tip being generally white. The hair is thick and woolly, and generally yellowish-olive in colour. These phalangers are the ring-tailed opposums of the Australians. From this genus is apparently derived the taguan flying-squirrel, or flying-phalanger (Petauroides volans), which ranges from Queensland to Victoria, and is the largest of the flying groupings. Its dentition is essentially similar to that of Pseudechurus, although there is one pair less of cheek-teeth, and the bushy tail is naked and prehensile at the tip. Reverting to the non-flying species, we have Gymnobelidae leuebteii, a small animal from Victoria representing a genus by itself, with the same dental formula as Pseudechurus, but cheek-teeth of a different type, the ears naked (instead of hairy) behind, glands on the chest and between the ears, and the tail long and evenly bushy to the tip. From this are evidently derived the flying-phalangers—flying-squirrels—of the genus Petaurus, which differ merely in the possession of a parahute, and are represented by several species, ranging from Australia (a species of Vombatus) to the Aru Islands, New Guinea, and New Ireland. Of the yellow-bellied species, P. australis, the habits are described by J. Gould as follows: "This animal is common in all the trees of New South Wales, particularly those which stand on the coast from Port Phillip to Moront Bay. In these vast forests trees of one kind or another are perpetually flowering, and thus offer a never-failing supply of blossoms upon which it feeds; the flowers of the various kinds of gums, some of which are of great magnitude, are the principal favourites. Like the rest of the genus, it is nocturnal in its habits, dwelling in holes and in the spouts of the larger branches during the day, and displaying the greatest activity at night while running over the small leafy branches, frequently even to their very extremities, in search of insects and the honey of the newly opened blossoms. Its structure being ill adapted for terrestrial habits, it seldom descends to the ground except for the purpose of passing to a tree too distant to be attained by springing from the one it wishes to leave. The tops of the trees are traversed by this animal with as much ease as the most level ground is by such as are destined for terra firma. If charged on foot to flight it ascends to the highest branch and performs the most enormous leaps, sweeping from tree to tree with wonderful address; a slight elevation gives its body an impetus which with the expansion of its membrane enables it to pass to a considerable distance, and even at the extremity of the leap; by this ascent the animal is prevented from receiving the shock which it would otherwise sustain."

A second species, P. sciuereus, in some ways one of the most beautiful of all mammalia, is shown in Fig. 2.

![Fig. 1.—Skull of Grey Cuscus (Phalanger orientalis).](image1)

![Fig. 2.—Squirrel Flying-Phalanger (Petaurus sciuereus).](image2)

hairy ears. There are six pairs of cheek-teeth, of which the last three are small and rounded, with blunt cusps, while the anterior teeth are sharp and of insectivorous type. The pigmy flying-phalanger feeds on honey from flowers and insects.

Like form, large, thin, and nearly naked ears, without tufts inside or at the base, sharp and rudimentary front claws and long sharp hind ones, and mouse-like tail, which is furry at the base, then scaly, and naked and prehensile at the tip. There may be either six or seven pairs of cheek-teeth, of which the hinder carry four small smooth cusps, and the first upper incisor is much longer than the other two. The striped phalangers (Dactylopsila) are larger animals, of the approximate size of a squirrel, easily recognized by the longitudinal yellow and black stripes of the fur, and the slender and elongated fourth front toe. The typical D. trirrigata is common to north Australia and New Guinea, but D. palpator, which has the fourth toe still more elongated, is exclusively Papuan. They have seven pairs of cheek-teeth, of which the four last are oblong and four-cusped; and the first lower incisor is longer than in any other phalanger. They apparently feed on both leaves and grubs, probably extracting the latter from cymns with the elongated toe. The tail is more or less bare on the under side of the tip.

The last group of the sub-family is represented firstly by the cuscuses, or cuscus (Phalanger), which are arboreal animals of the approximate size of cats, and range from the Solomon Islands through New Guinea and the Moluccas to Celebes, being, in fact, the only Old World marsupials found westwards of New Guinea. Externally they are characterized by their thick woolly fur, short or medium ears, which are hairy outside, and sometimes inside as well, by the naked and striated soles of the feet, and the long and markedly prehensile tail, of which the basal half is furred like the body, and the terminal half entirely naked. The number of cheek-teeth varies, owing to the frequent absence of some of the front ones, but there are generally seven pairs, of which the last four carry crescents internally and cusps externally. About ten species are known, of which the grey cuscus (P. orientalis) of Ambonya and Timor was discovered about 300 years ago, and was thus the first known Old World marsupial. In the spotted cuscus (P. maculatus) the males are marked with orange and white, while the females are uniformly greyish. Cuscuses are sleepy animals, feeding mainly on leaves, but also devouring birds and small mammals.

Nearly allied to the cuscuses are the typical Australian phalangers, or opossums, forming the genus Trichosurus. They differ from the cuscuses, among other features, by the thick and non-tapering tail being covered with bushy hair up to the extreme tip, which is naked, as is a narrow line along the middle of the terminal third
PHALANX—PHALTAN

(or rather more) of the lower surface, by the presence of a gland on the chest, and by the soles of the hind feet being hairy. In the skull the upper canine is separated from the outermost incisor, instead of close to it as in the cucuses (fig. 1). The best-known species is the brush-phalanger (E. vulpecula) of Australia, an animal of the size of a small fox, represented in Tasmania by the brown phalanger (E. vulpecula fuliginosus). The short-tailed phalanger (E. canina) represents the group ascribed to W. in the type of the genus Phalangis. The definite formula in both is $t, c, r, p, m, s$.

These animals are wholly arboreal and mainly nocturnal in their habits; and it is these which form the chief game in "oppossum-shooting" among the gum-trees by the moonlight.

The long-snouted phalanger is referred to under MARSUPIALIA.

(R. L.)*

PHALANX (Gr. φάλανξ, of unknown origin), the name, in Greek history of the arrangement of heavy-armed infantry in a single close mass of spearman (see AWX: History). In anatomy, the Latin plural phalanges is the term applied to the bones of the finger and toe, and in botany to a group of united stamen clusters. The term "phalanx" was adopted by F. C. M. Fourier (q.v.) as the name of the socialist community living in a "phalanstery.

PHALARIS, tyrant of Acragas (Agrigentum) in Sicily, c. 570–554 B.C. He was entrusted with the building of the temple of Zeus Atabyris in the citadel, and took advantage of his position to make himself despot (Aristotle, Politics, v. 10). Under his rule Agrigentum seems to have attained considerable prosperity. He supplied the city with water, adorned it with fine buildings, and strengthened it with walls. On the northern coast of the island the people of Himera elected him general with absolute power, in spite of the warnings of the prophet Steeper. As his name is not recorded, it seems possible that he succeeded in making himself master of the whole of the island.

He was at last overthrown in a general rising headed by Telemachus, the ancestor of Theron (tyrant 4th c. 488–472), and burned in his brazen bull.

After ages have held up Phalaris to infamy for his excessive cruelty. In his brazen bull, invented, it is said, by Perillus of Athens, the tyrant's victims were shut up and, a fire being kindled beneath, were roasted alive, while their shrivelled bodies were burnt to the bellowing of the bull. Perillus himself is said to have been the first victim. There is hardly room to doubt that we have here a tradition of human sacrifice in connexion with the worship of the Phoenician Baal (Zeus Atabyris) such as prevailed at Rhodes; when misfortune threatened Rhodes the brazen bulls in his temple bellowed. The Rhodians brought this worship to Gela, which they founded and colonised, and it is recorded by Herodotus (v. 98) that human sacrifices to Baal were common, and, though in Phoenicia proper there is no proof that the victims were burned alive, the Carthaginians had a brazen image of Baal, from whose down-turning eyes his children slid into the fire, and the image was preserved. Phalaris had a brazen man who pressed people to his glowing breast points to similar rites in Crete, where the child-devouring Minotaur must certainly be connected with Baal and the favourite sacrifice to the god of children.

The story of the bull cannot be dismissed as pure invention. Pindar (Pythia, i. 156), who lived less than a century afterwards, expressly associates this instrument of torture with the name of the tyrant. There was certainly a brazen bull at Agrigentum, which was carried off by the Carthaginians to Carthage, whence it was again taken by Scipio and restored to Agrigentum. In later times it is known that Phalaris Boile published his Dictionnaire de l'Académie des Sciences (1751) as "Dictionnaire de l'Académie des Sciences". The dictionnaire was a humane man and a patron of philosophy and literature. He is so described in the declarations ascribed to Lucian, and in the letters which bear his own name. Plutarch, too, though he takes the bull in a malicious light, says that Phalaris Boile is described as Phalaris the name of justice and a hatred of crime. Phalaris may thus have been one of those men who combine justice and even humanity with religious fanaticism (Suidas, s.n.: Did. Sic. ix. 20, 25; Polyb. vi. 71, 35; Green, Officis, ii. 7, iii. 6).

The letters bearing the name of Phalaris (148 in number) are now chiefly remembered for the crushingly exposure they received at the hands of a ferocious attacking critic, Richard Bentley in his "Dictionary of Coins," and his biographer, Charles Boyce, who had published an edition of them in 1695. The first edition of Bentley's Dissertation on Phalaris appeared in 1697, and the second edition, replying to the attacks which Boyce had made in the first, in 1700. From the mention in the letters of the towns (Phatia, Alosa and Tauronemum) which did not exist in the time of Phalaris, from the imitations of authors (Herodotus, Demosthenes, Epicles, Callimachus) who wrote long after he was dead, from the reference to tragedies, though tragedy was not yet invented in the lifetime of Phalaris, from the dialect, which is not Dorian but Attic, Nay, New or Late Attic, as well as from absurdities in the matter, and the entire absence of any reference to them by any writer before Stobaeus (c. A.D. 500), Bentley sufficiently proved that the letters were written by a sophist or rhetorician (possibly an Old Oligarch) who flourished in the 1st century B.c. After this, the letters, which he thought genuine, and in modern times, before their exposure by Bentley, they were thought highly of by some (e.g. Sir William Temple in his Essay on the Progress of Mankind, and William Walford, his Philological Dictionary, 1767). In both editions of the Epistles is by R. Hercher, in Epistolographi graeci (1793), and of Bentley's Dissertation by W. Wagner (with introduction and notes, 1893); see especially R. C. Jebb, Life of Bentley (1882).

PHALLICISM, or PHALLISM (from Gr. φαλλος), an anthropological term applied to that form of nature worship in which adoration is paid to the generative function symbolized by the phallus, the male organ. It is common among primitive peoples, and to the Phallic cult, a form of polytheism which had been prominent also among more advanced peoples, e.g. the Phoenicians and the Greeks. In its most elementary form it is associated with frankly orgiastic rites. This aspect remains in more advanced forms, but gradually it tends to give place to the joyous recognition of the principle of natural reproduction. In Greece for example, where phallicism was the essence of the Dionysiac worship and a phallic revel was the origin of comedy (see also HERMES), the purely material and the symbolical aspects no doubt existed side by side; the Orphic mysteries had to the intellectual Greeks a significance wholly different from that which they had to the common people. Phallic worship is specially prominent among the Celts, especially after the Caledonians came to Scotland. As a forerunner of the fertilizing effect of sun and rain, the savage sought to promote the growth of vegetation in the spring by means of symbolic sexual indulgence. Such were the rites which shocked Jewish writers in connexion with the worship of Baal and Astaroth (see BAAL, and cf. ATARGATES, Ishhtar). The same principle is at the root of the widespread nature worship of Asia Minor, whose chief deity, the Great Mother of the Gods (q.v.), is the personification of the earth's fertility; similarly in India worship is paid to divine mothers. Generally it should be observed that phallic worship is not specially or perhaps primarily paid to male deities, though commonly the more important deity is accompanied by a companion of the other sex, or is itself androgynous, the two symbols being found together.

In the Dionysiac rites the emblem was carried at the head of the processions and was immediately followed by a body of men dressed as women (the ἵθυβαλλι). In Rome the phalx was the most common amulet worn by children to avert the evil eye: the Latin word was fascinus (cf. Pliny, Nat. Hist. xix. 50, satyrica signa; Varro, Ling. Lat. vii. 97, ed. Müller). Pollux says that such emblems were placed by smiths before their forges. Before the temple of Aphrodite at Hierapolis (q.v.) were two huge phalli (180 ft. high), and other similar objects existed in all parts of the ancient world both in statuary and in paintings. Among the Hindus (see Hraswita) the phallus is called linga or lingam, with the female counterpart called yoni: the linga symbolizes the generative power of Siva, and is a charm against sterility. The rites classed together as Sakti puja represent the adoration of the female principle. In Mexico, Central America, Peru and other parts of America phallic emblems are found. The tendency, however, to identify all obelisk-like stones and tree-trunks, together with rites like circumcision, as remains of phallic worship, has met with much criticism (e.g. Robertson Smith, Religion of the Semites, 2nd ed., pp. 436 sqq.)

For authorities see works quoted under RELIGION: §§ A and B

PHALTAN, a native state of India, in the central division of Bombay, ranking as one of the Satara jagirs. Area, 307 sq. m.; pop. (1901), 45,739, showing a decrease of 31% in the decade. The estimated revenue is £13,000, and the tribute £630. The chief, whose title is nimbalkar, is a Mahrrata, tracing his descent to a grantee from a Delhi emperor in the 14th century. The town of Phaltan is 37 m. north-east of Satara; pop. (1901), 95,12.
PHANARIIOTES, a name derived from Phanar, the chief Greek quarter at Stamboul, where the eccenmical patriarchate is situated, and applied to those members of families resident in the Phanar quarter who between the years 1771 and 1821 were appointed hospodars of the Danubian principalities; that period of Moldo-Wallachian history is also usually termed the Phanariote epoch. It is not to be understood as marking the introduction into the principalities of the Greek element, which had already established itself firmly in both provinces, to both of which Greek princes had been appointed before the 18th century. But whereas the Greek families of earlier introduction gradually became merged in their country of adoption, the latter immigrants retained their separate nationality and grew to be powerful agents for furthering the spread of Graecism in the principalities.

The person raised to the princely dignity was usually the chief dragoman of the Sublime Porte, and was consequently well versed in contemporary politics and the statecraft of the Ottoman government. The new prince, who was compelled to purchase his elevation with a heavy bribe, proceeded to the country which he was selected to govern, and of the language of which he was in nearly every case totally ignorant, accompanied by a horde of needy hangers-on; and he and his acolytes counted on recouping themselves in as short a time as possible for their initial outlay by a sufficiency to live on after the termination of the prince's brief authority. It was the interest of the Porte to change the princes as often as possible, as the accession donation thus became due more frequently. When, owing to the numerous cases of treachery among the princes, the choice became limited to a few families the plan was hit upon of frequently shifting the prince from one province to the other: the prince of Wallachia, the richer of the two principalities, was always ready to pay a handsome douceur to avert his transfer to Yassay; the prince of Moldavia was equally ready to bribe his supporters at Constantinople to secure his appointment to Wallachia. To raise funds to satisfy the capricies of the Porte the princes became past masters in the art of spoliation, and the inhabitants, liable to every species of tax which the ingenuity of their Greek rulers could devise, were reduced to the last stage of destitution. The active part taken by the Greek princes in the revolt of 1820-21 induced the Porte to revert to the appointment of native princes.

PHANIAS, of Eresus in Lesbos, Greek philosopher, important as an immediate follower of and commentator on Aristotle, came to Athens about 332 B.C., and joined his compatriot, Theophrastus, in the Peripatetic school. He wrote works entitled Analytica, Categoricae and De interpretatione, which were either papyrus or critical commentaries, and seem to have added little to Aristotle's own writings. Alexander of Aphrodisias refers to a work πρὸς Διδωρόν, and Athenaeus quotes from another treatise, Against the Sophists. Outside philosophy, he and Theophrastus carried on the physical investigations of Aristotle; Athenaeus frequently quotes from a work on botany which manifests great care in definitions and accuracy of observation. From Plutarch (Life of Themistocles) we learn that he was regarded as an historian of importance. The chief of his historical works is the Pryaneis Eresii, which was either a history of his native place or a general history of Greece arranged according to the period of the Eresian magistracy. He wrote also works on the Tyrants of Sicily and on tyranny in general. The value of these books is attested by the frequency with which they are quoted on questions of chronology (e.g. by Plutarch, Suidas, Athenaeus). To the history of Greek literature he contributed works on the poets and on the Socratics, both of which are quoted.

He must be distinguished from another Phanias, a Stoic philosopher, disciple of Posidonius. Diogenes Laertius mentions a work of his which he compares Posidonius with, not arguing from physical principles.

PHANOCLES, Greek elegiac poet, probably flourished about the time of Alexander the Great. His extant fragments show resemblances in style and language to Philetas, Callimachus and Hermesianax. He was the author of a poem on paederasty. A lengthy fragment in Stoaebas (Florilegium, 64) describes the love of Orpheus for the youthful Calais, son of Boreas, and his subsequent death at the hands of the Thracian women. It is one of the best extant specimens of Greek elegiac poetry.

See N. Bach, Philetæae, Hermesianacis, et Phanociæ reliquiae (1829); L. Preller, Ausgewählte Aufsätze aus dem Gebiete der klassischen Alterthumswissenschaft (1864).

PHANTASMAGORIA, a name invented by a certain Philipilip in 1802 (from Gr, φαντασμα, phantasm, apparition; and ἀγών, assembly) for a show or exhibition of optical illusions produced by means of the projecting lantern (q.v.). The word has since been applied to any rapidly or strikingly changing scene, and especially to a disordered or fantastic scene or picture of the imagination.

PHARAOH (Par'oh), the Hebraized title of the king of Egypt (q.v.), in Egyptian Per-'o; Pharon in Herodotus represents the same. Its combination with the name of the king, as in Pharaoh-Necho, Pharaoh-Hophra, is in accordance with contemporary native usage: the name of the earlier Pharaoh Shishak (Sheshonk) is rightly given without the title. In hieroglyphic a king bears several names preceded by distinctive titles. In the IVth Dynasty there might be four of the latter: (1) identifying him with the royal god Horus; the name is commonly written in a frame representing the façade of a building, perhaps a palace or tomb, on which the falcon stands. (2) connecting him with the vulture and uraeus goddesses, Nekhabi and Buto of the south and north. (3) a hawk on the symbol of gold, signifying the victorious Horus. (4) the old titles of the rulers of the separate kingdoms of Upper and Lower Egypt, to be read stn, "butcher?" and byti, "beekeeper?" The personal name of the king followed (4), and was enclosed in a cartouche apparently symbolizing the circuit of the sun which alone bounded the king's rule. Before the IVth Dynasty the cartouche is seldom found: the usual title is (1), and (3) does not occur. In the IVth Dynasty the custom began of giving the king at his accession a special name connecting him with the sun: this was placed in the cartouche after (4), and a fifth title was added: (5) Si-rê, "son of the Sun-god," to precede a cartouche containing the personal name. The king was briefly spoken of by his title stn (see 4), or hmn-f, "his service," or Itsy, "liege-lord." These titles were preserved in the sacred writing down to the latest age. An old term for the royal palace establishment and estate was Per-o, "the Great House," and this gradually became the personal designation of Pharaoh (cf. the Grand Porte), displacing all others in the popular language.

PHARI, a town of Tibet. It is supposed to be the highest and coldest town in the world, being 15,000 ft. above the sea. As it commands the road between the Chumbi Valley and Lhasa and also one of the chief passes into Bhutan, Phari is of considerable military importance, and is defended by a large fort or Jong, which was occupied by the British expedition of 1904. Phari Jong is supposed to have been built about 1500 A.D., and was enlarged or rebuilt in 1792, under Chinese advice, as a defence against the British. It has the appearance of a medieval castle, and seems to have been built in imitation of the European style.

PHARISEES, a sect of the Jews first mentioned by Josephus, in his account (Ant. xiii. 5, 9) of the reign of Jonathan, the brother and successor of Judas Maccabaeus. The name, which may be translated "Separatists," indicates their devotion to the ideal, enforced by Ezra and Nehemiah upon the reluctant Jews, of a nation separate from all other nations in virtue of its
PHARMACOLOGY

systematic writers on the subject differ considerably in the exact meaning which they attach to the term pharmacology (φαρμακωτης, a drug; λόγος, a discourse), some making it much more comprehensive than others. Binz, for instance, defines it as treating of the origin, nature, chemical and physical qualities, physiological actions, and therapeutic uses of drugs; in France and in Italy it is restricted to the mere description of medicines and their preparations, the action and uses of which are usually included in the term therapeutics. In German-speaking countries, and by the majority of German writers, the meaning is now restricted to the study of the action of chemical substances (as apart from foods) on all kinds of animals, from bacteria up to man; it is, in fact, a comparative study of the action of chemical bodies on invertebrate and vertebrate animals. One of its practical aims is to obtain a wide and accurate knowledge of remedial substances in relation to their application in the treatment of disease, while another is to discover new or improved remedies. This meaning of the word has now become fixed in the English language by use and wont. The term pharmaco-dynamics (φαρμακωτης, δύναμις, power), which is etymologically more correct, is often used as its equivalent, but it has never become widely adopted. The study of pharmacological actions was at first almost entirely confined to those of remedial agents, and especially to the remedies in the different national pharmacopoeias, but in many cases it has now been extended to substances which are not used for curative purposes. The introduction into practical use of many medicines, such as paraldehyde, phenazone and strophanthus, has followed the study of their actions on animals, and this tends to be more and more the case. Pharmacology is a branch of biology; it is also closely connected with pathology and bacteriology; for certain drugs produce structural as well as functional changes in the tissues, and in certain diseases the peculiar symptoms are caused by foreign substances (toxins) formed by the infecting organism present in the body. The effects of many of these toxins bear a close resemblance to the action of certain well-known drugs, as in the case of tetanus toxin and strychnine, and are studied by the same methods of observation and research. It is impossible also to dissociate pharmacology from clinical therapeutics; the former investigates the agents which are used in the treatment of disease, the latter is concerned with their remedial powers and the conditions under which they are to be used. Hence the word "pharmaco-therapy" has come into
use, and most of the newer standard textbooks combine together the consideration of pharmacology and therapeutics. Pharmacology is also related to toxicology, as many remedial and other agents are more or less poisonous when given in large doses, but it does not include the detection, tests, and the other strictly medico-legal aspects of poisoning.

Pharmacology proper began as the result of the application of strictly experimental methods to physiology. The discovery (early in the 19th century) that plants owe their remedial and poisonous qualities to small quantities of definite active principles, such as alkaloids and neutral bodies, which can be extracted in a chemically pure condition, had also a very important effect on its development. We meet first with experiments made by investigators who perceived that observations on man and animals might lead to a better understanding of the action of drugs. In 1776 Wepfer and Conrad Brunner demonstrated on dogs the tetanizing action of nux vomica, and similar rough experiments were repeated from time to time with other substances by later investigators. In 1755 Menghini published an elaborate study of the action of camphor on a great variety of different kinds of animals. Albert von Haller (b. 1708) sought to elucidate the action of remedies by observations on healthy men, and in 1767 William Alexander made experiments on himself with drugs, which were, however, brought to an abrupt termination by his nearly killing himself. In 1776 Daries, by observations on himself and on cats, established the mydriatic action of belladonna and other atropoaceous plants. Hitherto no attempt had been made to determine what particular parts of the body were especially affected by drugs, but Fontana showed, in his great work (Florence, 1763) on the venom of the viper and on other poisons, that the general symptoms were brought about by an action on particular organs. He performed more than six thousand experiments, more than four thousand of which were on animals, and he determined the effects on the heart and other important structures. These analytical methods of research were well known to the second Monro in Edinburgh, and to his pupils, one of whom, William Alexander, wrote a thesis in 1790 entitled "De partibus corporis animalis quae viribus opii parent." His methods were doubtless known also to the French physiologist Magendie, who improved upon them, and who in 1809 published a research on the Upas Tricot and other strychnine-containing plants, in which he showed that their effects were due to an action on the spinal cord. The researches of his pupil, Claude Bernard, on curare, were equally exact and logical, and have served as the model for many subsequent investigations. In consequence, from the time of Magendie pharmacology may be said to have been put on a more exact basis. By the middle of the 19th century there were many workers on the subject, and the actions of such drugs as digitalis, morphine, alcohol, and many others had been frequently and minutely investigated. About this time Buchheim, professor of materia medica in Dorpat from 1846 to 1879, founded the first pharmacological laboratory on modern lines in Europe, and he introduced a more rational classification of drugs than had hitherto been in use, arranging them in groups according to their pharmacological actions. In the herbs and older treatises on materia medica and therapeutics no explanation is usually offered of the action of medicines, and in such works as that of Cullen (1789) only a few of the more obvious actions are occasionally explained according to the current theories of physiology and pathology. In works such as Pareira's Elements of Materia Medica and Therapeutics (1842), the physiological effects of medicines are usually described, but very briefly as compared with the materia medica. At the present day most textbooks dealing with medicinal agents and treatment devote a large part of their space to pharmacology, and a corresponding change has taken place in the teaching of the subject in universities and medical schools. Since Magendie's time numerous papers dealing with pharmacological subjects have appeared in the Journal of Anatomy and Physiology, the Journal of Physiology, Virchow's Archiv, and the principal medical periodicals of all countries. In 1873 the Archiv für experimentelle Pathologie und Pharmacology first appeared, in 1893 the Archives Internationales de Pharmacodynamie, and in 1900 The Journal of Pharmacology and Therapeutics (published at Baltimore, U.S.A.), all of which are chiefly or entirely devoted to pharmacology.

Methods of research are essentially those employed by physiologists, the action of substances being studied in the usual way on bacteria, leucocytes, frogs, rabbits and other animals. Not only are the general symptoms investigated, but it is necessary to carry out experiments on the nerves, muscles, circulation, secretions, &c., so as to get a more exact knowledge of the reasons of the general action. It is true that many of these animals react somewhat differently to drugs, both as regards each other and as regards man, but for the most part the differences are quantitative rather than qualitative. After carrying out a series of observations on animals, the drug can be assigned to its special group, and a good idea can be obtained of its possible practical value or the reverse; hence there is a saving of time and an avoidance of the necessity of testing its effects on man. The action of a drug may be called direct when it acts on any part to which it is immediately applied, or which it may reach through the blood; and indirect when one organ is affected secondarily to another, as, for instance, in strychnine poisoning when the muscles are violently contracted as the result of the action of the alkaloid upon the spinal cord. In a few cases the action is merely physical, but most frequently it is chemical in its nature, and is exerted on the living cell, the activity of which is either stimulated or depressed. In some cases the substances actually enter into a chemical combination with the protoplasm, which may be temporary or (much less frequently) permanent; in other cases they seem simply to modify or disturb the usual chemical activity of the cells. Prolonged or excessive stimulation invariably leads to depression or paralysis, the tissues becoming fatigued, and from this condition they may recover or they may not. When we come to consider more in detail the results of these actions we find that the various secretions of the body, such as the sweat, gastric juice, bile, milk, urine, &c., may be increased or diminished; that the heart may have its muscular or nervous apparatus stimulated or depressed; that the nerve-centres in the brain, medulla and spinal cord may be rendered more sensitive or the reverse; and that the general metabolism of the body may be altered in various ways. In addition, the fluid constituents, such as the lymph and blood, may have their composition and bulk considerably altered, while the special senses, the temperature, and, in short, every function and tissue, may be more or less affected.

Some drugs given in excess are poisons to all forms of protoplasm, but when given in doses much short of the lethal they usually exhibit a distinct tendency to affect specially, and at an early period, certain organs or tissues, and hence result differences in action; others may act only on certain organs, leaving the others practically untouched. It is often possible by appropriate dosage to contrive that these special organs or organs may be affected and the rest of the body left practically intact, and it is by taking advantage of these selective actions that remedial or therapeutic effects are usually obtained. Some substances have a very wide range of action, and involve a great variety of structures, while others, such as purgatives, have a very limited sphere. The action of drugs is often modified by circumstances peculiar to the individuals or animals to whom they are administered. In man the most important of these circumstances is age, but speaking broadly this is really a question of bulk, the child being affected like the adult, but by smaller doses. There are exceptions to this, however, as children are more affected by some drugs than by others substances, and vice versa. In old age also the nervous system and the tissues generally do not react so readily as in youth. Habit, race, personal temperament, emotional conditions, disease, the time and circumstances of administration, and other accidental causes may also modify the action in man. Some species of animals are much more susceptible to the action of certain drugs than others, a condition which depends on obvious
PHarmacology

or unknown structural or metabolic differences. In the same way some individuals show a special tendency to poisoning by doses of certain drugs which are harmless for the greater majority of mankind, and hence we get unexpected or unusual results, these arising from special susceptibility on the part of certain organs. These idiosyncrasies are not confined to drugs, but are seen with a few articles of food, such as eggs and shellfish. It is well known that the habitual consumption of certain drugs, such as tobacco, Indian hemp, opium, arsenic, alcohol and many others, gradually induces a condition of tolerance to their effects, so that large doses can be taken without causing symptoms of poisoning. In all cases, however, there is a limit, and after it is reached the ordinary effects of these substances are seen. Therefore, however, the grouping of substances which show poisonous effects on each repetition of the dose. The degree of tolerance often differs in individuals at different times and in different circumstances, and may become lost by breaking off the habit for a short time. The explanation generally given is that the nerve and other cells become accustomed to the drug, so that they cease to react, or that an antitoxin is formed which antagonizes the poison, or that the poison is rapidly destroyed in the body. Recent researches on arsenic and atropine, however, point to the leucocytes as playing an important part in the production of tolerance, as these gradually become capable of ingesting large amounts of the foreign substances, and thus render them more or less harmless to the tissues, until they are gradually excreted from the body. When the amount is too large to be dealt with by the leucocytes, poisoning seems to occur even in the most habituated. Tolerance is therefore analogous to, but not identical with, the immunity which takes place with the toxins of infectious diseases and snake poison. Certain substances, notably digitalis, lead, mercury and strychnine, exhibit what is called a cumulative action—that is to say, when small quantities have been taken over a period of time, poisoning or an excessive action suddenly ensues. The explanation in these cases is that the drug is absorbed more rapidly than it is excreted, hence there is a tendency to accumulation in the body until a paroxysm is reached when the amount becomes poisonous.

Bodies which have a close resemblance in their chemical constitution exhibit a similar resemblance in their pharmacological action, and as the constitution of the substance becomes modified chemically so does its action pharmacologically. Numerous researches have demonstrated these points with regard to individual groups of substances, but hitherto it has not been possible to formulate any fixed laws regarding the relationship between chemical constitution and physiological action.

When drugs are swallowed no absorption may take place from the alimentary canal; but, as a rule, they pass from there into the blood. Absorption may also take place from the skin, from the rectum, from the respiratory passages, or from wounds, and from direct injection into the subcutaneous tissue or into a blood vessel. Very rarely, as in the case of sugar salts, excretion does not take place; but usually the drug is got rid of by the ordinary channels of elimination. Just as drugs act upon the tissues, so they themselves are in many cases reacted upon, and broken up or altered. While in the alimentary canal they are subjected to the action of the digestive fluids and the varied contents of the stomach and intestines, and after absorption they come under the influence of the constituents of the blood and lymph, and of the chemical action of the tissue cells. Inorganic bodies, such as metals, may enter into innumerable combinations which may greatly modify their effects, and organic substances may be split up into simpler compounds by oxidation or reduction, or may be rendered more complex by synthesis.

The antagonism between certain drugs has been much studied in relation to their use as antidotes in poisoning, the aim being to counteract the effects rather than to obtain a direct physiological antagonistic action. Substances which directly antagonize each other by acting on the same tissue are few in number, but there are numerous instances in which the effects or symptoms may be obviated by acting on another tissue. Thus curare may stop strychnine convulsions, not by affecting the terminations of motor nerves, and chloroform may exercise the same effect by abolishing the irritability of the spinal cord. If two poisons act on the same tissue, one stimulating and the other paralyzing it, the paralyzing substance removes the action of the stimulant substance, not by bringing the tissue back to its normal state, but by abolishing its excitability; hence, although life may be saved by such an action, yet it can only be so within certain limits of dosage, because the antagonism is never complete at every point.

Speaking in the widest sense, every substance has an action or effect, however, inorganic or organic, i.e., pharmacological substances have come to be limited to those which are used as drugs, or which have a distinct action upon the animal organism. Such substances are derived from (1) the chemical elements and their compounds; (2) plants; and (3) animals. The first class includes such substances as iodine, mercury, iron, carbon, and their various compounds, and such bodies as alcohol, chloroform and chloral, all of which are found in nature or can be prepared by ordinary chemical processes of manufacture. From plants many substances are obtained which at the present time we are unable to make in the chemical laboratory, and of the constitution or composition of which we are in many cases ignorant. Some of these, such as resins, gums, essential oils and fats, are readily obtained as natural exudations or by very simple manipulations, while others, such as the alkaloids, glucosides and vegetable acids, often require to be extracted by very complex processes. Substances obtained from animals include gland secretions, pepsin and other ferments, musk, cod-liver oil, &c., and to these may be added various antitoxins. The classification of substances having pharmacological actions presents so many difficulties that no satisfactory or universally adopted method has yet been proposed. Our knowledge presents so many gaps, and the mode of action of many remedies is so obscure and imperfectly understood, that any arrangement adopted must be more or less tentative in character. The close alliance between pharmacology, therapeutics and clinical medicine has induced many authors to treat the subject from a clinical point of view, while its relationships to chemistry and physiology have been utilized to elaborate a chemical and physiological classification respectively as the basis for systematic description. Certain writers in despair have adopted an alphabetical arrangement of the subject, while others have divided it up into inorganic, vegetable and animal substances. These last-mentioned methods are far behind our present state of knowledge, and need not be discussed here. The objection to a strictly chemical classification is, that while many substances closely allied chemically have a somewhat similar action in certain respects, yet in others they differ very widely—a striking example of which is given in the case of sodium and potassium. A physiological classification according to an action on the brain, heart, kidney or other important organ becomes still more bewildering, as many substances produce the same effects by different agencies, as, for instance, the kidneys may be acted upon directly or through the circulation, while the heart may be affected either through its muscular substance or its nervous apparatus. A clinical or therapeutic classification into such divisions as anaesthetics, expectorants, bitters, and so on, according to their practical applications, also leads to difficulties, as many drugs are employed for numerous purposes. The idea of deriving the grouping pharmacological substances would be in reference to their chemical action on living protoplasm, but as yet our knowledge is too scanty for this. At the present time the method adopted by Buchheim, or some modification of it, is the most scientific. As the result of painstaking investigations he grouped together all those substances having similar actions, giving to each group the name of its best-known or most thoroughly investigated member. Once the groups were more or less fixed any new substance could, when
its action was determined, it referred to its own group, and thus be placed or classified. As few substances are absolutely identical in action, but only broadly similar, it is often difficult to divide sharply one group from another. In a résumé it is manifestly impossible to go into the details of every pharmacological substance, but we shall therefore confine ourselves to those groups which are of practical importance. Many individual drugs are described under their own headings.

**Group I. Acids.**—This includes sulphuric, hydrochloric, nitric, phosphoric, tannic, tartaric, and citric acids. They have no specific action upon the health, but they are capable of acting upon the skin in the same manner as the alkalis, though in much smaller quantities. In the presence of an active acid, all of them give their action to their acidity. Many of the other acids, such as carbonic and salicylic, have specific effects which have no relationship to their acid reaction. The concentrated acids have an intense local action, which they produce in considerable quantities, causing more or less irritation. When considerably diluted they are only slightly irritating; externally applied and in the stomach they have an antisep tic action; they increase the secretion of saliva, and thus assist in the treatment of chronic dyspepsia and of certain astringent alkaloids present, and are absorbed into the blood as neutral salts, being excreted chiefly in the urine. In small doses they somewhat increase general metabolism. Boric acid only belongs partially to this group, as it and its compound borax have certain specific actions in addition.

**Group II. Alkalis.**—This includes caustic potash, caustic soda, and sodium carbonate. Their carbonates, bicarbonates, and bicarbonates of sodium, sodium, potassium, and sodium. They are almost completely ionized in solution, and give their action to their alkaline characteristics. They are very quickly absorbed, and they are slightly stimulants and cleansers of the skin. Calcium salts form insoluble soaps with fats, and combine with albumen in a manner which makes it opaque and unabsorbable. Apart from alkaline effects, these metals differ considerably pharmacologically. Potassium and lithium have a depressing action upon the nervous system, ammonium salts have a stimulating action, and sodium salts exert a more or less irritant effect. Calcium and sodium have actions somewhat similar to that of potassium. Most of these substances are normally present in the body, and are indispensable for healthy existence. They are contained in sufficient amount in our ordinary dietary to supply the needs of the organism.

**Group III. Easily absorbed Salts.**—Sodium chloride may be taken as the type of those salts which diffuse readily, and are therefore difficult to confine. Sodium carbonate, potassium chloride, ammonium chloride, the alkaline iodides and bromides, also belong partly to this group, although most of them have also specific actions. Locally they cause considerable irritation, and are thus the better the content is absorbed by the alimentary canal. From the stomach and intestines they are rapidly absorbed, and are excreted from the blood, increasing all secretions and the general metabolism. These effects are apparently due to their irritating action upon individual cells.

**Group IV. Salts absorbed with difficulty.**—This group includes the sulphates of sodium, potassium, and magnesium, the acetate and the carbonate of calcium, the tartrate of sodium, and the gypsum of calcium and magnesium. Locally their action is slight, but when taken internally, dissolved in water, they are not absorbed from the alimentary canal except in very limited amount. They are, therefore, only partly available for the body, as they attract and retain large quantities of water, and at the same time slightly stimulate the mucous membrane, they come to have a purgative action and form the well-known group of saline cathartics. They may be either cathartics, emetics, or purgatives, depending upon their concentration.

**Group V. Heavy Metals.**—These include iron, manganese, aluminium, chromium, zinc, copper, silver, gold, platinum, lead, mercury, and bismuth. Some of these metals, as bismuth and tin, have some of these metals are very limited in their actions after absorption, still locally they have certain effects in common due chiefly to their chemical action on albumen. Their soluble salts combine with albumen and cause a most definite and strong specific action. They are either purgative or caustic, while weaker ones are astringent simply, or even soothing. They are all astringents. Their insoluble compounds are much less active locally than the soluble, and in many cases are only effect in the stomach and bowels, the mixture being absorbed more slowly, and with acid stabilization of the stomach, their value as an anesthetic. When given in small amounts mixed with air it produces a condition of exhilaration.

**Group XI. Water.**—Water acts directly as a diuretic and solvent. It therefore increases the flow of urine, and is a diuretic to the kidneys, while it also stimulates the general metabolism of the body and the excretion of nitrogenous products. Mineral waters are used for the same purpose, but their effect is very much modified, and depend largely upon other substances, such as alkaline salts, iron, arsenic, sulphides, carbonic acid, &c.

**Group XII. Tannic Acid.**—Tannic acid is present in small quantities in the galls of many plants, but in larger quantity in gall-nuts, oak bark, bearberry leaves, tannin root, catechu, kino,
PHARMACOLOGY

Phenol.—This includes the homologous group of bodies chemically allied to benzol, such as carbolic acid, sulphonarols, cresols, xylol, toluol, paraffin oil, and others. They are used chiefly as disinfectants, antiseptics, and oxidizing agents, and vary in their action from mildly irritating to highly destructive, the effects of different members of the group not always being related to the degree of acidity or alkalinity. They are used mainly as disinfectants and antiseptics, and the more irritating of them increase the flow of blood to the pelvic organs, and may thus stimulate the uterus, or in large doses cause abortion. The various camphors, such as laurel camphor, borneo camphor, menthol, and camphor, are oxidized derivatives of camphor, and differ only from it in the degree of their stimulating effect on the respiratory tract. They are used chiefly as stimulants to the respiratory tract.

GROUP XVI. Phenol.—This includes the homologous group of bodies chemically allied to benzol, such as carbolic acid, sulphonarols, cresols, xylol, toluol, paraffin oil, and others. They are used chiefly as disinfectants, antiseptics, and oxidizing agents, and vary in their action from mildly irritating to highly destructive, the effects of different members of the group not always being related to the degree of acidity or alkalinity. They are used mainly as disinfectants and antiseptics, and the more irritating of them increase the flow of blood to the pelvic organs, and may thus stimulate the uterus, or in large doses cause abortion. The various camphors, such as laurel camphor, borneo camphor, menthol, and camphor, are oxidized derivatives of camphor, and differ only from it in the degree of their stimulating effect on the respiratory tract. They are used chiefly as stimulants to the respiratory tract.

GROUP XVII. Alcohol.—This group also includes a very large number of chemical bodies, only a few of which are mentioned here. Included in this group are the amyl alcohols, propyl alcohol, ethyl, and others, paraldehyde, sulphonal, chloroform, methyl chloride, chloral hydrate, butylicloral hydrate, and almost any number of derivatives obtained from the body, such as choline and its derivatives on bacteria, white blood corpuscles, yeast, and similar organisms. After absorption most of them exercise a depressant effect upon the nervous system, and are capable of reducing high temperature.

GROUP XVIII. Nitrates.—This group includes amyl nitrite, ethyl nitrite, nitroglycerine, and related substances, as well as nitrite, nitrite, nitrite-nitrate, and nitrite-tetranitrate, and many other compounds containing nitrous or nitric acid. The latter becomes reduced to nitrous in the body, and thereby exercises its characteristic effects. These consist chiefly in a reduction of the muscular tone of the blood vessels and a dilatation of the latter, and also in a general depressant effect upon the circulatory system. Under their action more heat is lost from the body, the general metabolism is diminished and the temperature falls. With some of them, such as chloroform and chloral, the stimulation period is short compared with the narcotic period, while with others, such as ether, the reverse is the case.

GROUP XIX. Alkalois.—This embraces a very large number of chemical bodies, each with a specific action, which may be based on their influence on the respiratory tract, on the nervous system, or on the cardiovascular system. The most important of the alkaloids are the stimulants, which affect the nervous system, assisting the respiration and producing a feeling of warmth.

GROUP XX. Ether.—This includes a very large number of chemical bodies, each with a specific action, which may be based on their influence on the respiratory tract, on the nervous system, or on the cardiovascular system. The most important of the ethers are the hypnotics, which affect the nervous system, assisting the respiration and producing a feeling of warmth.

GROUP XXI. Anaesthetics.—This group includes a very large number of chemical bodies, each with a specific action, which may be based on their influence on the respiratory tract, on the nervous system, or on the cardiovascular system. The most important of the anaesthetics are the analgesics, which affect the nervous system, assisting the respiration and producing a feeling of warmth.

GROUP XXII. Stimulants.—This group includes a very large number of chemical bodies, each with a specific action, which may be based on their influence on the respiratory tract, on the nervous system, or on the cardiovascular system. The most important of the stimulants are the excitants, which affect the nervous system, assisting the respiration and producing a feeling of warmth.

GROUP XXIII. Sedatives.—This group includes a very large number of chemical bodies, each with a specific action, which may be based on their influence on the respiratory tract, on the nervous system, or on the cardiovascular system. The most important of the sedatives are the hypnotics, which affect the nervous system, assisting the respiration and producing a feeling of warmth.

GROUP XXIV. Antispasmodics.—This group includes a very large number of chemical bodies, each with a specific action, which may be based on their influence on the respiratory tract, on the nervous system, or on the cardiovascular system. The most important of the antispasmodics are the spasmolytics, which affect the nervous system, assisting the respiration and producing a feeling of warmth.

GROUP XXV. Analgesics.—This group includes a very large number of chemical bodies, each with a specific action, which may be based on their influence on the respiratory tract, on the nervous system, or on the cardiovascular system. The most important of the analgesics are the anesthetics, which affect the nervous system, assisting the respiration and producing a feeling of warmth.

GROUP XXVI. Antiseptics.—This group includes a very large number of chemical bodies, each with a specific action, which may be based on their influence on the respiratory tract, on the nervous system, or on the cardiovascular system. The most important of the antiseptics are the disinfectants, which affect the nervous system, assisting the respiration and producing a feeling of warmth.

GROUP XXVII. Antimetics.—This group includes a very large number of chemical bodies, each with a specific action, which may be based on their influence on the respiratory tract, on the nervous system, or on the cardiovascular system. The most important of the antimetics are the emetics, which affect the nervous system, assisting the respiration and producing a feeling of warmth.

GROUP XXVIII. Antiperistaltics.—This group includes a very large number of chemical bodies, each with a specific action, which may be based on their influence on the respiratory tract, on the nervous system, or on the cardiovascular system. The most important of the antiperistaltics are the antispasmodics, which affect the nervous system, assisting the respiration and producing a feeling of warmth.

GROUP XXIX. Antiperistaltics.—This group includes a very large number of chemical bodies, each with a specific action, which may be based on their influence on the respiratory tract, on the nervous system, or on the cardiovascular system. The most important of the antiperistaltics are the analgesics, which affect the nervous system, assisting the respiration and producing a feeling of warmth.

GROUP XXX. Antiperistaltics.—This group includes a very large number of chemical bodies, each with a specific action, which may be based on their influence on the respiratory tract, on the nervous system, or on the cardiovascular system. The most important of the antiperistaltics are the antispasmodics, which affect the nervous system, assisting the respiration and producing a feeling of warmth.

GROUP XXXI. Antiperistaltics.—This group includes a very large number of chemical bodies, each with a specific action, which may be based on their influence on the respiratory tract, on the nervous system, or on the cardiovascular system. The most important of the antiperistaltics are the analgesics, which affect the nervous system, assisting the respiration and producing a feeling of warmth.

GROUP XXXII. Antiperistaltics.—This group includes a very large number of chemical bodies, each with a specific action, which may be based on their influence on the respiratory tract, on the nervous system, or on the cardiovascular system. The most important of the antiperistaltics are the antispasmodics, which affect the nervous system, assisting the respiration and producing a feeling of warmth.
as a stimulant-narcotic in Peru and Bolivia. Small doses excite the nervous system, while larger doses are depressing. The chief action, in the practical point of view is its power of paralysing the terminations of sensory nerves.

5. Atropine, hyoscyamine, homatropine, dубoise, daturne and some other substances have a paralysing action upon the ends of the motor and secretory nerves. In large doses they produce a powerful nerve paralysis, and when the secretions of the secretions, and among other actions dilate the pupil and increase the rapidity of the heart by paralysing the vagus. In addition they have a stimulating action on the central nervous system.

6. Nicotine, piritune and lobeline are the active principles of tobacco and other substances which are smoked as stimulant narcotics. In large doses they produce a powerful nerve paralysis. When they are usually taken they exercise a gently stimulating effect upon the nervous system. Pilocarpine has an action closely allied to that of nicotine, but as it is much less poisonous (the effects produced by human doses being chiefly excessive sweating and salivation), it is capable of being utilized in medicine. Muscinae has a very close resemblance in action to pilocarpine.

7. Physostigmine, the active principle of the Calabar bean, acts chiefly as a stimulant to voluntary and involuntary muscular action, and at the same time exercises a depressing effect upon the spinal cord. It contracts the pupil.

8. Cocaine, gelonine and sparteine all exert a paralysing effect on the terminations of the motor nerves, to the implication of which the weakened gait and other symptoms are due.

9. Adrenalin, delpheline and many of their derivatives have a very powerful paralysing action on the motor nerves.

10. Apomorphine is essentially a muscular poison, but owing to the fact that minute doses stimulate the vomiting centre and cause emesis before any other symptoms are observable, its emetic action is utilized.

11. Emetine acts as a general depressant to the nervous system in animals. In man its chief effect is its emetic action, which seems to be entirely local to irritate the stomach.

12. Atropine. Several of the other alkaloids found in cinchona bark act very much like quinine. They all depress the conducting power and the grey matter of the spinal cord, and to a much less extent that of the brain. They lessen the general metabolism and lower the temperature. In small doses they have an antiparalytic action, and in larger doses they produce an action on the peripheral motor nerves which is a good dry heat-regulating, but are all non-nitrogenous neutral bodies.

Their action is exerted upon muscle, and chiefly upon the muscle of the heart and blood vessels. The individual muscle-fibres contract individually and not generally. The reaction of the heart is rendered more complete, the pulse is slowed, and the blood-pressure is raised. The slowing of the heart is partly brought about by an action on the vagus centre.

13. Phrenic. In large doses the action of picrotoxin is exerted chiefly on the medullary nerve centres, whereby irregular tonic-clonic convulsions are produced; in minute doses it stops the secretion of sweat.

GROUP XX. Saponin. —Saponin and many allied bodies form an abundant soapy-looking froth when shaken up with water, and they are contained in a very large number of plants, the chief of which are the Quillaja saponaria, Polypogon senega, sarsaparilla, and others, known collectively as soapworts. They all act as local irritants in the alimentary canal, and after absorption are more or less depressing to the muscular and nervous systems. They produce salivation, increase the flow of sweat.

GROUP XXI. Cyanogen. —This includes compounds of cyanogen such as hydrocyanic (prussic) acid, cyanides of potassium, sodium, &c., cherry-laurel water, amygdalin, bitter almonds and other chemical and vegetable substances which readily yield hydrocyanic acid. Hydrocyanic acid is a general protoplasmic poison, and all the lower organisms being very susceptible to its action, while in the higher animals it speedily depresses or paralyses all forms of nervous tissue and, in minute doses, to a considerable extent, a bright scarlet compound and interfering with respiration. It kills by its paralysing effect on the motor ganglia of the heart and on the respiratory centres.

GROUP XXIV. Ferments. —These include such bodies as pepsin, diastase, the pancreatic ferment, papain, the pine-apple ferment, taka-diastase and others, and serve to convert starch into saccharo (the common invert sugar).

GROUP XXV. Animal Glands and Secretions. —Of these the thyroid gland, the parotid bodies, the spleen, the bile, the bone marrow, the ovaries and some others have been investigated fully. Speaking generally, when given in small doses their action on the healthy organism is slight or nil, but in disease some of them are capable of acting as substitutes for deficient secretions.

The term poisons is used to designate those substances which antagonize the toxins formed in the body by pathogenic organisms, the toxins of snake venom and other animal poisons, and vegetable toxins such as abrin, ricin, &c. A healthy person can be rendered susceptible by the administration of large doses of these poisons, and this immunity is due to antitoxins which are found in the blood-serum and which are products of the blood cells. The nature of the antitoxin substance is not definitely known, but they combine with and destroy the poisons. In some cases these diseases a similar antitoxin forms, and in cases which recover it counteracts the toxin, while the germs are destroyed by the tissues.

The term serums are prepared from the sera of animals, and such serums are injected subcutaneously in diphtheria, tetanus, streptococcic infections, plague, snake-poisoning, cholera and other similar diseases. They do not act as a rule harm healthy men even in large quantities, but when repeated they often cause serious symptoms due to the body becoming more sensitive to the action of the horse-serum in which they are contained.

GROUP XXVII. Neutral. —This includes cod-liver oil, almond oil, olive oil, lard, &c., all of which act as foods when taken internally, and have a merely physical emollient action when applied externally. Lanolin, linseed oil, wax, spermaceti, &c., also belong to this group. The paraffins or carbonaceous fats, have much the same effect when applied externally, but they are not nutritive.

GROUP XXIX. Sugars, Starches, Gums, Gelatin, &c. —Although the carbohydrates or allied bodies are the chief substances to which the term carbohydrate are applied, they are for the most part purely mechanical or dietetic.

Terminology in Therapeutics. It may be useful to give here a general explanation of the common names used in the therapeutic classification of drugs. It is convenient to divide drugs and other substances used in medicine into groups according to the part of the system on which they chiefly act, though, as stated above, many drugs act in more than one manner and could come under several groups.

I. Drugs acting on the blood vessels, which either dilate the vessels when taken internally or applied locally, or contract the superficial arteries. Irritants (Lat. irritare, to excite) include: Rubeoacents (Lat. rubefacere, to make red), which cause the skin to become red from dilatation of the blood vessels; Venecians (Lat. vestica, a bladder), which irritate sufficiently to cause the blood-serum to exude and form vesicles or blisters, &c. cantharides; Pulsatilis (Lat. pulsata, a blister), still more powerful in their irritant nature, cause the skin to become red and humpy with oil. Escharotiles (Gr. ἐσχαρος, hearth, braizer; hence mark of a burn, "scar") or Caustics (Gr. καυστος, to burn), cause the death of the part, e, silver nitrate and nitric acid. The term constrictor is used when an irritant is applied to the skin for the purpose of relieving pain or congestion by dilating the superficial vessels. Drugs which contract the vessels and diminish exudation comprise Astringents (Lat. astringere, to draw close), while Stopics (Gr. στηπτος) interfere with contraction and dilatation of the vessels (term causing to stand) are substances applied either locally or internally in order to arrest bleeding; cold, aperient, ergot and the per-salts of cocaine are well known.

II. Drugs acting on the digestive tract. Sialographs (Gr. σιαλος, spittle, ἱκανος, leading) increase the flow of saliva, e.g. mercury; Antisialographs decrease the flow, e.g. belladonna. Aromatic herbs, i.e. those herbs of the albaus (Lat. albus) or "white" species, Stomachics (Gr. ὑπονεκος) have the same effect. The term Carminatives (Lat. carminare, to card) wool, adopted from the old medical theory of humour, is generally applied to pungent substances which help to expel gas from the stomach by stimulating the movement
of its contents. Emetics (Gr. τάρσος, vomiting) are substances given for the purpose of causing vomiting, e.g. ipecacuana or apomorphine. Anti-emetics or Sedatives (Lat. sedare, to compose) arrest vomiting either by their central or local action, e.g. opium, codeine, barbiturates. Purgatives (Gr. καθαρός, cleansing), which produce watery evacuations. Cholagogues (Gr. χολά, bile, ἄργως, leading) are purgatives which act by increasing the flow of bile, either by causing an increased secretion of bile or by acting on it onwards by stimulating the intestinal contractions (e.g. calomel).

III. Drugs acting on parasites. Anthelmintics (Gr. ἀνθελμιντικά, against worm) are drugs that act on parasites inhabiting the intestine. The term vermicide (Lat. vermis, worm) is applied to drugs which directly kill the enzootia, while vermifuge (Lat. vermis, worm, fugere, to put to flight) is applied to drugs which repel or expel the vermin for the purpose of expelling the worm. Parasiticides or anti-parasitic destroy parasites; the terms are usually restricted to those acting on skin-parasites as contrasted with intestinal ones.

Diuretics (Gr. διύρησις, through, δρομός, the urine) increase the flow of urine, while lithotritypicis (Gr. λίθος, stone, ρυθμός, to rub, grind down) are drugs used for the prevention of formation of urinary calculi.

VII. Drugs or substances acting on the bodily heat. Antipyretics (Gr. ἀντίπυρος, fever, ἀπιρίειν, to lose) either increase the heat or diminish its production; e.g. phenacetin, cold water, etc.

VIII. Drugs or substances acting on the skin. Diaphoretics (Gr. διαφωτεῖς, to carry through) increase the amount of sweat, either by acting directly on the sweat centres or on the nerve terminals. The word Sudorific (Lat. sudor, sweat) is applied to them when they act very powerfully. Anthridiotics or Anthriderotics (Gr. ἀνθρίδωτος, sweat) diminish the secretion of sweat. Emollients (Lat. mollis, soft) are substances which soften and protect the parts. Demulcents (Lat. demulcere, soften), soothe the skin or mucous membrane.

XI. Drugs acting on metabolism. Alteratives are drugs which alter the course of a disease, the mode of action being unknown. Tonics are drugs which increase the muscular tone of the body by acting either on the stomach, heart, spinal cord, etc.

XII. Drugs acting on the nervous system. Anaesthetics (q.v.) diminish or abolish the pain of the central or peripheral nervous system; and Analgesics (Gr. ἀνα, priv., δόλος, pain) relieve pain only, but, as in Analgesics (Gr. ἀναγειρέω, sense of pain), sensitivity is unaltered. Stimulants are those which lead to excitation of the mental and muscular faculties; they include both narcotics (Gr. νακτικός, sleep) or Somnifics (Lat. sopor, a deep sleep) are drugs which produce sleep without causing cerebral excitement. Narcotics (Gr. νάρκη, sleep, sleep) are drugs which produce unconsciousness, and may in large doses depress the functions of respiration and circulation.

XIII. Drugs which arrest the progress of putrefaction. This is either by inhibiting the growth of micro-organisms (Antiseptics) or by destroying them when present (Disinfectants). (H. L. H.)

PHARMACOPOEIA (lit. the art of the φάρμακον, or drug-compounder), in its modern technical sense, a book containing directions for the identification of simples and the preparation of compound medicines, and published by the authority of a government or of a medical or pharmaceutical society. The name has also been applied to similar compendiums issued by private individuals. The first work of the kind published under government authority appears to have been that of Nuremberg in 1542; a passing student named Valerius Cordus showed a collection of medical receipts, which he had selected from the writings of the most eminent medical authorities, to the physicians of the town, who urged him to print it for the benefit of the apothecaries, and obtained for his work the sanction of the senate. An apothecary, known by the name of Antidiofarics, had been published under the auspices of the college of medicine of Florence. The term "pharmacopoeia" first appears as a distinct title in a work published at Basel in 1561 by Dr A. Foes, but does not appear to have come into general use until the beginning of the 17th century. Before 1542 the works principally used by apothecaries were the treatises on simples by Avicenna and Serapion; the De synonymis and Quod pro quo of Simon Janensis; the Liber servitorum of Balchusin Abazerizem, which described the preparations made from plants, animals and minerals, and was the type of the chemical portion of modern pharmacopoeias; and the Antidotearium of Nicholas de Salerno, containing Galenic compounds arranged alphabetically. Of this last work there were two editions in use—Nicolaus magnus and Nicolaus parus; in the latter several of the compounds described in the larger edition were omitted and the formulae given on a smaller scale.

Until 1617 such drugs and medicines as were in common use were sold in England by the apothecaries and grocers. In that year the apothecaries obtained a separate charter, and it was enacted that no grocer should keep an apothecary's shop. The preparation of physicians' prescriptions was thus confined to the apothecaries, upon whom pressure was brought to bear to dispense the drugs in powder, and to publish a pharmacopoeia in May 1618 by the College of Physicians, and by the power which the wardens of the apothecaries received in common with the censors of the College of Physicians of examining the shops of apothecaries within 7 m. of London and destroying all the compounds which they found unfavourably prepared. This, the first authorized London Pharmacopoeia, was selected chiefly from the works of Meuzee and Nicolaus de Salerno, but it was found to be so full of errors that the whole edition was cancelled, and a fresh edition was published in the following December. At this period the compounds employed in medicine were often heterogeneous mixtures, some of which contained from 20 to 70, or more, ingredients, while a large number of simples were used in consequence of the same substance being supposed to possess different qualities according to the source from which it was derived. Thus crabs' eyes, pearls, oyster-shells and coral were supposed to have different properties. Among other ingredients entering into some of these formulae were the excrements of human beings, dogs, mice, geese and other animals, calcini, human skull and moss growing on it, blind puppies, earthworms, &c. Although other editions of the London Pharmacopoeia were issued in 1621, 1632, 1659 and 1677, it was not until the edition of 1721, published under the auspices of Sir Hans Sloane, that any important alterations were made. In this issue many of the ridiculous remedies previously in use were omitted, although a good number were still retained, such as dogs' excrement, earthworms, and moss from the human skull; the botanical names of herbal remedies were for the first time added to the official ones; the simple distilled waters were ordered of a uniform strength; sweetened spirits, cordials and ratibias were omitted as well as several compounds no longer used in London, although still in vogue elsewhere. A great improvement was effected in the edition published in 1746, in which only those preparations were retained which had received the approval of the majority of the pharmacopoeia committee; to these was added a list of those drugs only which were supposed to act most efficaciously or perfectly. This edition was followed in further the older formulae by the rejection of superfluous ingredients. In the edition published in 1788 the tendency to simplify was carried out to a much greater extent, and the extremely compound medicines which had formed the principal remedies of physicians for 2000 years were discarded, while a few powerful drugs which had been considered too dangerous to be included in the Pharmacopoeia of 1765 were restored to their previous position. In 1809 the French chemical nomenclature
was adopted, and in 1815 a corrected impression of the same was issued. Subsequent editions were published in 1824, 1836 and 1851.

The first Edinburgh Pharmacopoeia was published in 1699 and the last in 1841; the first Dublin Pharmacopoeia in 1807 and the last in 1830.

The preparations contained in these three pharmacopoeias were not all uniform in strength, a source of much inconvenience and danger to the public, when powerful preparations such as dilute hydrocyanic acid were ordered by the one country and dispensed according to the national pharmacopoeia in another. In consequence of this inconvenience the Medical Act of 1858 ordained that the General Medical Council should cause to be published a book containing a list of medicines and compounds, to be called the British Pharmacopoeia, which should be a substitute throughout Great Britain and Ireland for the separate pharmacopoeias. Hitherto these had been published in Latin. The first British Pharmacopoeia was published in the English language in 1864, but gave such general dissatisfaction both to the medical profession and to chemists and druggists that the Government resolved to have another one prepared, and this was published in 1867. This dissatisfaction was probably owing partly to the fact that the majority of the compilers of the work were not engaged in the practice of pharmacy, and therefore competent rather to decide upon the kind of preparations required than upon the method of their manufacture. The necessity for this element in the construction of a pharmacopoeia is now fully recognized in other countries, in most of which pharmaceutical chemists are represented on the committee for the preparation of the legally recognized manuals.

National pharmacopoeias now exist in the following countries: Austria, Belgium, Chile, Denmark, France, Germany, Great Britain, Crete, so as to ensure uniformity of strength, chemical and pharmaceutical preparation. Russia, Spain, Sweden, Italy, Switzerland, the United States of America and Venezuela. All the above-mentioned were issued under the authority of government, and their instructions have the force of law. The British Pharmacopoeia, the only one of these, was prepared by commissioners appointed by medical and pharmaceutical societies, and has no other authority, although generally accepted as the national textbook.

The French Codex has probably a more extended use than any other pharmacopoeia outside its own country, being, in connexion with Dorval's L'Officier, the standard for druggists in a large portion of Central and South America; it is also official in Turkey. The official pharmacopoeia of Great Britain has, in comparison, but one fifth of the number of entries, and only the most popular and nearly all the medicinal preparations were described in the Pharmacopoeia, in which all new remedies and their preparations, uses and doses are recorded, and in the Pharmacopoeia have never been quite up to date. This difficulty has hitherto been met by the publication of such non-official manuals as Squire's Companion to the Pharmacopoeia and Heatlie's Modern Pharmacopoeia, in which all new remedies and their preparations, uses and doses are recorded, and in the Pharmacopoeia have never been quite up to date. This difficulty has hitherto been met by the publication of such non-official manuals as Squire's Companion to the Pharmacopoeia and Heatlie's Modern Pharmacopoeia, in which all new remedies and their preparations, uses and doses are recorded, and in the former the varying strengths of the same preparations in the different pharmacopoeias are also compared. The need of such works to supplement the Pharmacopoeia is evident, for even though more vastly used than the Pharmacopoeia itself, the first containing in 18 and the second in 13 editions at comparatively short intervals. In England the task of elaborating a new Pharmacopoeia was intrusted to a large and influential body of chemists and druggists, and legally the pharmacist has not, as in other countries, a voice in the matter, notwithstanding the fact that, although the medical practitioner is naturally the best judge of the drug or preparations which we afford the best therapeutic result, he is not so competent as the pharmacist to say how that preparation can be produced in the most effective and satisfactory manner, nor how the purity of drugs can be tested. In the preparation of the fourth edition of the British Pharmacopoeia in 1898 some new departures were made. A committee of the Pharmaceutical Society of Great Britain was appointed to prepare the General Council of the Pharmacy on pharmaceutical matters and the valuable assistance rendered by it is acknowledged in the preface of that work. A census of prescriptions was taken to ascertain the relative frequency with which each official drug was ordered, and suggestions and criticisms were sought from various medical and pharmaceutical bodies at home and in the colonies. As regards the purely pharmaceutical part of the work a committee of reference was appointed to prepare the Pharmacopoeia, and a new body, the Committee of the Medical Council, was appointed to report to the Pharmacopoeia Committee of the Medical Council.

It is not too much since the passing of the Adulteration of Food and Drugs Act conferring the title of the Pharmacopoeia as a legal standard for the drugs and preparations contained in it. The British Pharmacopoeia is in the preface as only "intended to be an ordinary medical and pharmaceutical work," and this is so engaged in the preparations of medicines throughout the British Empire one uniform standard and guide whereby the nature and composition of substances to be used in medicine may be ascertained and of drugs for the pure and of drugs for the ascertained purity obtainable, and this standard would be too high too expensive for ordinary purposes. The use of trade synonyms in the Pharmacopoeia, such as saltpetre for purified potassium nitrate, and milk of sulphur for precipitated sulphur, is partially adopted for this difficulty, and has proved to be a mistake, since it affords ground for legal prosecution if a chemist sells a drug of ordinary commercial purity for trade purposes, instead of the purified drug required by the Pharmacopoeia. It would be impossible to enforce this, and this would not be the case if the trade synonym were omitted. For many drugs and chemicals not in the Pharmacopoeia there is no standard of purity that can be used under the Adulteration of Drugs Act. In some cases, as for instance the accuracy of that of these drugs and essential oils which are also in the Pharmacopoeia, a legal standard of commercial purity is much needed. This subject formed the basis of discussion at several meetings of the Pharmaceutical Society, and the results have been embodied in a work entitled Suggested Standards for Foods and Drugs, by C. G. Moor, which indicates the average degree of purity of non-official drugs and another which indicates the highest degree of purity obtainable in commerce of those used in medicine.

An important step has also been taken in this direction by the publication under the authority of the Council of the Pharmaceutical Society of Great Britain of a series of Pharmacopoeial Tables, which the characterizes and tests for the purity of many non-official drugs and preparations are given as well as the character of many gauzy preparations and antiseptics that have come into use. As the character of preparations and will not yet be included in the Pharmacopoeia. This work may also possible serve as a standard under the Adulteration of Food and Drugs Act for the purity and strength of drugs not included in the Pharmacopoeia and as a standard for the commercial growth of all of those in the Pharmacopoeia which are used for non-medical purposes.

Another legal difficulty connected with modern pharmacopoeia is another of them of synthetic chemical remedies, the processes for preparing which have been patented, whilst the substances are sold under trade-mark names such as veronal. The scientific chemical name is often long and unwieldy, and the pharmacist is compelled to use a trade-mark name instead of the name under which it is sold by the patentee. In this case the pharmacist is compelled to use the more expensive patented article and the patentee of the name. If he uses the same article as the name under which it is sold by the patentee, then he lays himself open to prosecution for infringement of patent rights. The only plan, therefore, is for the pharmacist to use the chemical name (which cannot be patented) and to indicate it by a period. The phrase "British Pharmacopoeia" is not included in the Pharmacopoeia—to use the scientific and chemical name given in the British Pharmaceutical Codex.

International Pharmacopoeia.—Increased facilities for travel have brought the medical practice of one country to a large extent, and the medical practitioner is naturally the best judge of the drug or preparations which we afford the best therapeutic result, he is not so competent as the pharmacist to say how that preparation can be produced in the most effective and satisfactory manner, nor how the purity of drugs can be tested. In the preparation of the fourth edition of the British Pharmacopoeia in 1898 some new departures were made. A committee of the Pharmaceutical Society of Great Britain was appointed to prepare the General Council of the Pharmacy on pharmaceutical matters and the valuable assistance rendered by it is acknowledged in the preface of that work. A census of prescriptions was taken to ascertain the relative frequency with which each official drug was ordered, and suggestions and criticisms were sought from various medical and pharmaceutical bodies at home and in the colonies. As regards the purely pharmaceutical part of the work a committee of reference was appointed to prepare the Pharmacopoeia, and a new body, the Committee of the Medical Council, was appointed to report to the Pharmacopoeia Committee of the Medical Council.

It is not too much since the passing of the Adulteration of Food and Drugs Act conferring the title of the Pharmacopoeia as a legal standard for the drugs and preparations contained in it. The British Pharmacopoeia is in the preface as only "intended to be an ordinary medical and pharmaceutical work," and this is so engaged in the preparations of medicines throughout the British Empire one uniform standard and guide whereby the nature and composition of substances to be used in medicine may be ascertained and of drugs for the pure and of drugs for the ascertained purity obtainable, and this standard would be too high too expensive for ordinary purposes. The use of trade synonyms in the Pharmacopoeia, such as saltpetre for purified potassium nitrate, and milk of sulphur for precipitated sulphur, is partially adopted for this difficulty, and has proved to be a mistake, since it affords ground for legal prosecution if a chemist sells a drug of ordinary commercial purity for trade purposes, instead of the purified drug required by the Pharmacopoeia. It would be impossible to enforce this, and this would not be the case if the trade synonym were omitted. For many drugs and chemicals not in the Pharmacopoeia there is no standard of purity that can be used under the Adulteration of Drugs Act. In some cases, as for instance the accuracy of that of these drugs and essential oils which are also in the Pharmacopoeia, a legal standard of commercial purity is much needed. This subject formed the basis of discussion at several meetings of the Pharmaceutical Society, and the results have been embodied in a work entitled Suggested Standards for Foods and Drugs, by C. G. Moor, which indicates the average degree of purity of non-official drugs and another which indicates the highest degree of purity obtainable in commerce of those used in medicine.

An important step has also been taken in this direction by the publication under the authority of the Council of the Pharmaceutical Society of Great Britain of a series of Pharmacopoeial Tables, which the characterizes and tests for the purity of many non-official drugs and preparations are given as well as the character of many gauzy preparations and antiseptics that have come into use. As the character of preparations and will not yet be included in the Pharmacopoeia. The phrase "British Pharmacopoeia" is not included in the Pharmacopoeia—to use the scientific and chemical name given in the British Pharmaceutical Codex.
PHARMACOSIDERITE—PHARMACY

been produced. The standardization of preparations of patent medicines, as regards the amount of active principles they contain, can only conveniently and economically be done in operating on large quantities, and must naturally lead to the preparations being standardized in accordance with the metric system. It is not yet certain that deterioration may not be caused by too strict a standardization, in such as those of ergot or digitalis, so that it is somewhat questionable whether the standardization is of permanent value. It must be borne in mind that careful selection of the drug, and skill in its preservation and preparation by the retail pharmacist, who should be personally responsible for the quality and purity of the preparations he sells. Although the metric form of the British Pharmacopoeia has failed, a project for an imperial pharmacopoeia which should be adapted to the general and local requirements of all parts of the British Empire has met with better success. With the aid of the medical and pharmaceutical authorities in each of the seventy and administrative divisions of the British Empire an Indian and Colonial addendum to the British Pharmacopoeia of 1898 was compiled and such an addendum on this subject has been officially sanctioned in the countries indicated at the foot of the monographs. This was regarded as a preparatory step to the publication of a complete imperial pharmacopoeia.

Several unofficial universal pharmacopoeias have been published in England and in France, which serve to show the comparative strength of parallel preparations in different countries. The metric or decimal mode of calculation and the centigrade scale of temperature are, and are likely to be, adopted by all international pharmacopoeias. The metric system in Britain (in which the metric equivalents are now given) and in some instances of Greece. The majority omit chemical formulae. An alphabetical arrangement is followed in all. The maximum dose given in the formulae is the dose which the physician must indicate on his prescription, if he exceeds this limit, by using a note of exclamation after each article, that he purposely intends such a dose to be employed. The great increase of medical literature in all countries, and the universal introduction of the metric system, has led to the adoption in almost every country of all the really valuable remedial agents, and the more extended use of active principles has given rise to an approximation in strength of their solutions. The difficulty of nomenclature could probably be overcome by a list of synonyms being given with each article, and that of language by the use of Latin. The greatest stumbling-blocks in the way of uniformity are the tinctures and extracts—a class of preparations containing many very powerful drugs, but in which the same name does not always indicate the same thing; thus, extract of aconite signifies an extract of the root in the pharmacopoeias of the United States, Japan and Russia, extract of the leaves in the Danish and Portuguese, insipid juice of the fresh leaves in the Greek, and alcoholic extract of the root in that of Spain and Italy, and alcoholic extract of the dried leaves in the Chilean pharmacopoeias. It appears probable, however, that the growth of pharmacological chemistry will indicate, in time, which of those in use form the most active and trustworthy preparations, while the general adoption of the metric system will lead to closer approximation of strength than has hitherto been the case. The adoption of the metric system is the nearest approach to the pharmacopoeia comes nearest to that uniformity which is so desirable in such preparations, as the tinctures of the fresh plants are all prepared with equal parts of the drug and alcoholic menstruum; similarly with the extracts, with the exception of a few such with one part of the drug in five parts of alcohol of given strength; ethereal tinctures are in the proportion of one part in ten; and the solid tinctures or extracts contain one part of the alkaloid in ninety-nine of menstrum.

Homoeopathic and eclectic practitioners as well as dentists have also their special pharmacopoeias. See Bell and Redwood, Progress of Pharmacy (London, 1880); Scherer, Literaturapharmakoosaurus (Leipzig and Sorau, 1822); Flint, Report on the Pharmacopoeias of all Nations (Washington, 1883). (E. M. H.)

PHARMACOSIDERITE, a mineral species consisting of hydrated basic ferric arsenate, 2FeAsO₄·Fe(OH)₃·3H₂O. Crystals have the form of a small, sharply defined cube of an olive- or grass-green colour, and occur together in considerable numbers on the matrix of the specimens. On account of its cubic form the mineral was early known as a 'cube' mineral (Gen. Würfelkristall, a German term). The name, given by J. F. Hegner in 1813, alludes to the arsenic and iron present (φάκασος, poison, and ὄξις, iron). The faces of the cube are striated parallel to one diagonal, and alternate corners are sometimes replaced by faces of a tetrahedron. The crystals are feebly doubly refracting, and in polarized light exhibit a banded structure parallel to the cube faces. The hardness is 2½ and the specific gravity 2.8. Recent analyses prove the presence of a small but variable amount of potassium (K₂O, 2.68—4.13%) in the Cornish crystals, though in those from Hungary there is only a trace; this constituent appears to take the place of basic hydroxide in the above formula. A curious property is to be observed when a crystal of pharmacosiderite is placed in a solution of ammonia—within a few minutes the green colour changes throughout the whole crystal to red, on clinging the reaction in dilute hydrochloric acid the green colour is restored. Natural crystals are sometimes honey-yellow to brown in colour, but this appears to be due to alteration.

Pharmacosiderite is a mineral of secondary origin, the crystals occurring attached to gozzani quartz in the upper part of veins of copper ore. It was found in some abundance at the end of the 18th century in the copper mines of the St Day district in Cornwall, and has since been found at a few other localities, for example at Königshof near Schenmitz in Hungary, and in the Tident district in Utah. (L. S. J.)

PHARMACY, a term which in the original Greek form signified the use of any kind of drug (φάκασος), poison or spell, and hence also poison and witchcraft. In the modern signification it is applied to the act of preparing, preserving and compounding medicines, according to the prescriptions of physicians. It was used first in this sense in 1597.

In the earliest periods of the world's history of which we have any record, this art, like that of the perfumer, was practised by a special class of the priesthood, as in the case of Eleazar (Num. iv. 16), and that of medicine by another class (Lev. xvi.). Egyptian papyri, which are the earliest records of medicine, contain directions for the priests of Isis when, accompanied by the chanter of incantations and spells, they visited the sick1. A papyrus of Sent, 3300 b.c, gives directions as to the preparation of prescriptions. In the Ebers papyrus, 1550 b.c, mention is made of blisters, ointments, clysters, mineral and vegetable drugs. The art of the apothecary is alluded to very early in the Old Testament history (Exod. xxx. 23—35 and in xxxvii. 20) and again in the time of Solomon (Eccles. x. 9), but this word, which is translated parfumeur in the French version, only indicates that the preparation of fragrant unguents and incense formed, even at that early date, a part of the art of the physicians. The priests' drugs mentioned, viz. galbanum, myrrh, stacte, frankincense, calamus, cassia and cinnamon, were all of them used in perfumes, even the myrrh being probably the kind distinguished at the present time in the Bombay market as perfumed myrrh or bissabol, which still forms an ingredient of the joss sticks used as incense in the temples in China. The myrrh mentioned in Gen. xxxvii. 35 is described under another Hebrew word, and refers to ladanum, a fragrant resin produced in Cyprus, and the use of this drug, as well as that of cinnamon and cassia, indicates even at that early period a knowledge of the products of Samoiland, Arabia and the East Indies and the existence of trade between the farther East and Egypt. In China also at a very early period the art of pharmacy was practised. Ching-Hong, a contemporary of Menes I of Egypt, was learned in the art, and made decoctions and extracts of plants. The materia medica of the Chinese at the present day affords an excellent illustration of the changes that have taken place in the use of drugs, and of the theories and superstitions that have guided the selection of these from the earliest ages, inasmuch as it still comprises articles that were formerly used in medicine, but have now been utterly discarded. Thus the doctrine of signatures is evident in the use of the celebrated Ginseng root of China, which, like that of the mandrake (Gen. xxx. 14—16), owed its employment to the fact that the root often divides into branches resembling the forms and legs of a man, and this resemblance gave rise to the belief that it conferred strength and virility. The same belief is shown in the botanical names applied to many plants, e.g. Pulmonaria, Hepatica, Scrophularia, and others.

The astrological belief that plants, animals and minerals are under the influence of the planets is shown in the older names of some of the metals, e.g. Saturn for lead, Venus for copper, and Mars for iron, and the belief that the colours of flowers

1 The Egyptians believed that the medicinal virtues of plants were due to the spirits who dwelt within them.
indicated the particular planet they were under led to their use in diseases and for constitutions supposed to be under the same planet. Physicians to this day head their prescriptions with a sign that originally meant an invocation to Jupiter, but now represents the word *recipe*.

The belief, which is still held by the Chinese, that the excreta of animals retain the properties and peculiarities of the animals from which they are derived, led to the use in medicine of these disgusting remedies, which are still sold in drug shops in China, and were only omitted from the English Pharmacopoeia as late as 1771. At that date the science of chemistry was very imperfectly known, and the real constituents of ordinary remedies were not understood that different virtues were attributed to different products containing the same constituents. Thus, prepared oyster-shells, coral, pearls, crabs' "eyes" and burnt hart's horn were regarded as specifics in different complaints, in ignorance of the fact that they all contain, as the chief ingredients, calcium phosphate and carbonate. The celebrated Gascoigne's powder, which was sold as late as the middle of the 19th century in the form of balls like sal prunella, consisted of equal parts of crabs' "eyes," the black tips of crabs' claws, Oriental pearls, Oriental bezoor and white coral, and was administered in jelly made of hart's horn, but was prescribed by physicians chiefly for wealthy people, as it cost about forty shillings per ounce. Superstition also entered largely into the choice of remedies. Various parts of criminals, such as the thigh bone of a hanged man, moss grown on a human skull, &c., were used, and even the celebrated Dr Calpeper in the 17th century recommended "the ashes of the head of a coal black cat as a specific for such as have a skin growing over their sight."

In course of time the knowledge of drugs, and consequently the number in use, gradually increased, and some of the preparations made in accordance with the art attained a celebrity that lasted for centuries. Thus diacylon plaster was invented by Menocrates in A.D. 51, and was used by him for the same purpose as it is employed to-day. An elixir of opium, known as *Mithradatum*, was invented by Mithradates VI., king of Pontus, who lived in constant fear of being poisoned, and tested the effects of poisons on criminals, and is said to have taken poisons and their antidotes every day in the year. The prescription for the general antidote known as Mithradatum was found with his body, together with other medical MSS., by Ponspey, after his victory over that king. The prescription was improved by Damocrates and Andromachus, body physicians to Nero. The first was subsequently known as *Mithradatum Damocraisi*, and the second as *Theriaca Andromachi*, the name *Theriaca* or *Theriac* being derived from the snake called Tyrsus, the sting of which was credited to it by Andromachus. The former contained 55, or, according to some formulae, 72 ingredients, and occurs in all the dispensatories, from that of Corvus Valerius up to the pharmacopoeias of the 19th century; and aromatic preparations of opium are still used, under the name of *Theriaka* in Persia. The *Theriaca* prepared at Venice had the highest reputation, probably because in Venice the component parts were exposed to the inspection of wise men and doctors for two months, to determine whether they were or were not fit for use. The apothecaries' ordinance at Nuremberg provided that no *Theriaca* should in future be branded with the seal of the city unless it had been previously examined and declared worthy of the same by the doctors of medicine, and that every druggist must know the age of the *Theriaca* he sold. Inasmuch as its action changed very materially with age, "the buyer should in all instances be informed, so that he may not be deceived." The last public preparation of *Theriaca* took place at Nuremberg in 1754.

In A.D. 77-78 Dioscorides of Anazarba, in Cilicia, wrote his great work on materia medica, which still remains the most important work on the plants and drugs used in ancient times (of which about 400 were enumerated) and until the 17th century was held as the most valuable guide to medicinal plants and drugs extant. Nearly 100 years afterwards Galen, the imperial physician at Rome (A.D. 131-200), who was learned in surgery, pharmacy and materia medica, added about 200 more plants to those described by Dioscorides.

Galen believed in the doctrine of humours originated by Hippocrates, which supposes the condition of the body to depend upon the proper mixture of the four elements, hot, cold, moist and dry, and that drugs possess the same elementary qualities, and that on the principle of contraries one or other was indicated, e.g. a cooling remedy for a feverish state. This doctrine was held for many centuries, and drugs are classed by all the old herbalists as having one or other of these qualities in a greater or less degree. Galen is said to have invented hiera-pierna, which he employed as an emmenagogue; it is still used in England as a domestic remedy. In the 6th century Alexander of Tralles used colchicum for gout, iron for anaemia, and rhubarb in liver weakness and dysentery. The practice of pharmacy was extended by the Arabian physicians, and the separation of it from medicine was recognized in the 8th, and legalized in the 11th century. The practice of "polyparmacy," or the use of a large number of ingredients in prescriptions, which was common in the middle ages, was greatly due to the view enunciated by Alkekendo, and held by one of the Arabian schools of medicine: that the activity of medicine increases in a duplicate ratio when compounded, and it would be by the prescription of the 18th century that the practice was altogether discontinued in the pharmacopoeias, although the theory was shown to be incorrect by Averroes in the 12th century.

The establishments for dispensing medicines at Cordova, Toledo and other large towns under Arab rule, were placed under severe legal restrictions. Frederick II. in A.D. 1233 passed a law, which remained in force for a long time in the two Sicilies, by which every medical man was required to give information against any pharmacist who should sell bad medicine. The pharmacists were divided into two classes, the *stationarii*, who sold simple drugs and non-magisterial preparations at a tariff then prescribed, and the *apothecarii*, whose business it was to dispense scrupulously the preparations of medical men; all pharmaceutical establishments were placed under the surveillance of the college of medicine. In the monastic period pharmacy was to a great extent under the control of the religious orders, particularly the Benedictines, who, from coming into contact with the Arabian physicians, devoted themselves to pharmacy, pharmacology and therapeutics; but, as monks were forbidden to shed blood, surgery fell largely into the hands of barbers, so that the class of barber-surgeons came into existence, and the sign of their skill in blood-letting still appears in provincial districts in England in the form of the barbee's pole, representing the application of bandages. In England the separation between medicine and pharmacy was somewhat later than on the continent of Europe. The earliest record of an apothecary's shop in London was in 1345. The status of the apothecary, as subordinate to the physician in the time of Henry VIII., is evident from the following, out of 21 rules laid down by a prominent apothecary, who was a cousin of Anne Boleyn: "His garden must he at hand, with plenty of herbs and seeds and roots. He must read Dioscorides. He must have mortars, pots, filters, glasses and boxes clean and sweet. He must have two places in the shop, one most clean for physic, and the base place for chirurgical stuff. He is neither to increase nor to diminish the physician's prescription; he is neither to buy nor to sell rotten drugs. He is only to meddle in his own vocation; and to remember that his office is only to be the physician's cook."

The drugs used by the physicians and apothecaries were purchased from the grossari or sellers in gross, who were subsequently called grocers, some of whom specialized as druggists and others as chymists or chemists. The apothecaries, who were the pharmacists of those days, were not represented by any corporate body, but in the reign of King James I., in 1606, were incorporated with the Company of Grocers. This arrangement was not, however, approved of by the physicians, who obtained in 1617 a separate charter for the apothecaries, to the number of 114, which was the number of physicians then
practising in London. At the same time it was enacted that no grocer should keep an apothecary's shop, and that no surgeon should sell medicines, and that the physicians should have the power to search the shops of the apothecaries within 7 m. of London under a penalty of £100 in case of a refusal to permit it. Soon after the apothecaries were formed into a separate corporation, consideration was given to the possibility of introducing means to prevent the frauds and adulterations practised by the grocers and druggists, and, to remedy the evil, established a manufactury of their own in 1626 so that they might make preparations for their own members. The frauds and adulterations were probably due in part to the apothecaries, for Dr Merrit, a collegiate physician of London, stated that "such chemists which sell preparations honestly make complain that few apothecaries will go to the price of them." The medicinal preparations which required the aid of a furnace, such as mineral earths, were undertaken by the chemists, who probably derived their name from the Alchemists, who flourished from the 14th to the 16th centuries. When the word was discovered to be derived from an Arabic prefix and a Greek word the prefix was dropped. In the 19th century the word chemist became altered to chemist, although the original spelling is still continued to a small extent. The curious signs on the coloured carboys in chemists' windows, which were commonly to be seen until the middle of the 19th century, were signs used by the alchemists to indicate various chemical substances. In 1604 the apothecaries had increased from 114 to nearly 1000, and many of them, having acquired a knowledge of the uses of medicine, began to prescribe medicines for their customers and to assume the functions of the physician, who retired in 1607 by establishing dispensaries, where medicines could be procured at their intrinsic value, or at cost price. The assistants employed at these dispensaries after a time appear to have gone into business on their own account, and in this way the dispensing chemists, as a class, appear to have originated.

In 1748 the Apothecaries' Corporation obtained a charter empowering them to license apothecaries to sell medicines in London, or within 7 m., and intended to use it to restrain chemists and druggists from practising pharmacy, and to prohibit physicians and surgeons from selling the medicines they prescribed; but the apothecaries, by paying increased attention to medical and surgical practice, had not only alienated the physicians and surgeons, but materially strengthened the position of chemists and druggists as dispensers of prescriptions. When a further attempt was made in 1815 to bring a bill into parliament including provisions for prohibiting the practice of pharmacy by uneducated persons, and giving power to examine dispensing chemists, the latter became alarmed, and, finding that the provisions of the bill were entirely in the interests of the apothecaries, and directed against chemists and druggists, the latter took measures to oppose it in parliament, which were so far successful as to prevent apothecaries from interfering in any way with, or obtaining any control over, chemists and druggists. In 1841 another attempt was made by the apothecaries to control the trade of chemists and druggists on the ground that no adequate examination or education in pharmacy existed, and that such should be instituted, and be controlled by the apothecaries and physicians, but the latter disclaimed any desire to take an active part in the matter. The chemists and druggists, recognizing that no institution for the systematic education and examination of chemists and druggists existed in England, and that no proof could be given that each individual possessed the necessary qualifications, decided that this objection must be met, and that pharmacy must be placed upon a more scientific footing. They therefore resolved upon the foundation of a voluntary society, under the title of the Pharmaceutical Society of Great Britain, for advancing the knowledge of chemistry and pharmacy, and for the systematic education of those who should practise the same, also for protecting the collective and individual interests and privileges of all its members, in the event of any hostile attack in parliament or elsewhere." This society was instituted in 1841, the original founders being chemists and druggists in the metropolis and provincial towns. On the 18th of February 1843 a royal charter of incorporation was granted to the society, and a permanent status was thus acquired. Chemists in business before the granting of the charter were entitled to join the society as members, but those who wished to join it subsequently could do so only on condition of passing an examination for the professional knowledge of pharmacy. A school of pharmacy was instituted, and a museum and library started. The chemical laboratory in connexion with the school was, when first instituted, the only one in England for teaching purposes, and the museum is now reputed to be the best pharmaceutical one in the world, the library now containing about 13,000 volumes.

The examinations are three in number. The first is of a preliminary character, qualifying for registration as a student or apprentice; in lieu of this examination, certificates of matriculation at a university, and those of certain other educational bodies, are accepted. The second examination qualifies for registration as a chemist and druggist. This is known as the minor examination, and must be passed before anyone can legally dispense, compound and sell scheduled poisons. The subject included are: botany, vegetable morphology and physiology, chemistry, physics, materia medica, pharmacy, dispensing, posology, the reading of medicines, and a knowledge of poisons. The Poisons and Pharmacy Act of 1908 (section 4) has given the society power to regulate the preliminary training, arrange a curriculum, and divide the qualifying examination into two parts, so that an individual, instead of passing the standard of pharmaceutical education the Continent is likely to take place within a short period. Degrees in science and pharmacy are granted by the universities of Manchester and Glasgow, and other universities were in 1910 considering the question of granting degrees.

The third, or major examination, which qualifies for registration as a pharmaceutical chemist, is not, like the minor, a compulsory one, but ranks as an honour examination. The education for this examination has kept pace with the rapid advances of science, and all the following subjects now receiving attention: the microscopic structure of plants and drugs, so as to detect adulterations and impure substances; the uses of poisons and poisons; the design of the Poisons and Pharmacy Act of 1908 (section 4) has given the society power to regulate the preliminary training, arrange a curriculum, and divide the qualifying examination into two parts, so that an individual, instead of passing the standard of pharmaceutical education the Continent is likely to take place within a short period. Degrees in science and pharmacy are granted by the universities of Manchester and Glasgow, and other universities were in 1910 considering the question of granting degrees.

Preparations or admixtures containing 0.2% or more of strychnine; opium and all preparations and admixtures containing 1% or more of morphia; picro-toxine; prussic acid and all preparations and admixtures containing 0.1% or more of prussic acid; salvin and its oil, and all preparations or admixtures containing salvin or its oil. None of these may be sold to any person who is unknown to the seller, unless introduced by a person known to the seller, and not until after an entry is made in a book kept for the purpose, stating, in the prescribed form, the date of sale, name and address of purchaser, the name and quantity of the article sold, and the purpose for which it is sold. No person shall be permit the purchase of these preparations except by a person who has an address in the country, and then only in small villages, where the pharmacist cannot make a living. The principle of "one man one shop" is general; a pharmacist may not own more than one shop in the same town.

On the continent of Europe the dispensing of prescriptions is confined to pharmacists (pharmaciens and apotheciers). They are not allowed to prescribe, nor the medical profession to dispense, except under special licence, and then only in small villages, where the pharmacist could not make a living. The principle of "one man one shop" is general; a pharmacist may not own more than one shop in the same town.

In Holland he may not enter into any agreement, direct or indirect, with a medical man with regard to the supply of medicines. In Austria, Germany, Italy, Rumania and Russia the number of pharmacies is limited according to the population. In France, Switzerland, Belgium and Holland the number is not limited, and every qualified pharmacist has the right to open a shop or buy a pharmacy. Where the number of pharmacies is limited by law prescriptions may only be dispensed at pharmacies. The dispensing of medicines in the country, and a certified copy given to the patient, written on white paper if for internal use, or on coloured paper (usually orange yellow) if for external use. The price of the drugs and the tariff for dispensing prescriptions is fixed by government authority. In Russia a prescription containing any of the poisons indicated in the schedules A and B in the Russian pharmacopoeia may not be repeated, except by order of the doctor. The use of pharmacopoeia preparations made by manufacturers is allowed, but the seller is held responsible for their purity and strength. The prices charged for dispensing are lower in countries where the number of pharmacies is limited by law, the larger returns enabling the profit to be lessened.

The educational course adopted in different countries varies as to the details of the subjects taught. The preliminary, or classical examination, is usually that of university matriculation, or its equivalent. The period of study is eighteen months in Denmark or Norway, and two in Austria, Finland, Germany, Portugal, Russia, Sweden and Switzerland, three in Belgium, France, Greece and Italy, four to six in Holland, and five in Spain. In Great Britain the period of study is voluntary, and usually occupies only one year. Two or three years of apprenticeship is required in many countries, including Great Britain, but none in Belgium, Greece, Italy or Spain.

The subject of patent medicines is but little understood by the general public. Any medicine, the composition of which is kept secret, but which is advertised on the label for the cure of diseases, must in Great Britain bear a patent medicine stamp equal to about one-ninth of its face value. The British Medical Association published in 1907 a work on Secret Remedies; what they cost and what they contain. The analyses published in this work show that nearly all the widely advertised secret remedies contain only well-known and inexpensive drugs. The Pharmaceutical Society on the other hand has issued a Pharmaceutical Journal Formula, including several hundred formulae of proprietary medicines sold by pharmacists, so that it is now possible for any medical man to ascertain what they contain. The government accepts all the therein published formulae as "known, admitted and approved" remedies, and therefore not requiring a patent medicine stamp. In this way widely advertised secret remedies can be replaced by medicines of known composition and accepted value in any part of the world. Most continental countries have issued stringent laws against the sale of secret remedies, and these have been lately strengthened in Germany, France and Italy. In Switzerland secret remedies cannot be advertised without submitting the formula and a sample of the remedy to the board of health.

(E. M. H.)
PHARNABAZUS. Persian soldier and statesman, the son of Pharnaces, belonged to a family which from 475 governed the satrapy of Phrygia on the Hellespont, from its headquarters at Dascylion, and, according to a discovery by Th. Nödeke, was descended from Otanes, one of the associates of Darius in the murder of Sméris. Pharnabazus first appears as satrap of this province in 373, when he had received orders from Darius II. to send in the outstanding tribute of the Greek cities on the coast, he, like Tissaphernes of Caria, entered into negotiations with Sparta and began war with Athens. The conduct of the war was much hindered by the rivalry between the two satraps, of whom Pharnabazus was by far the more energetic and up- right. After the war he came into conflict with Lysander (q.v.; see also PELOPONNESIAN WAR), who tried to keep the Greek cities under his own dominion, and became one of the causes of his overthrow, by a letter which he sent to the ephors at Sparta (Plut. Lys. 19; Nepos, Lys. 4; Polyæn. vii. 19). He received Alcibíades at his court and promised him means to go up to the king to reveal the intrigues of Cyrus, but when the Spartans insisted on his death he yielded to their demand for his assassina- tion (Plut. Aleib. 37 sqq.; Diod. xiv. 11). When in 399 the war with Sparta broke out he again tried to conduct it stritu- ously. With the help of Conon and Evagoras of Salamis he organized the Persian fleet, and while he was hard pressed on land by Agesilaus he prepared the decisive sea-battle, which was fought in August 304 at Cnidus under his and Conon's command, and completely destroyed the Spartan fleet. He sent support to the allies in Greece, by which the walls of the Pteraius were rebuilt. But in the war on land he struggled in vain against the lethargy and disorganization of the Persian Empire; and when at last, in 387, in consequence of the embassy of Antalcidas to Susa, the king decided to conclude peace with Sparta and to enter again into close alliance with her, Pharnabazus, the principal opponent of Sparta, was recalled from his command in high honours, to marry Apame, a daughter of the king (Plut. Artas. 27). In 385 he was one of the generals sent against Egypt, and in 377 he was ordered to prepare a new expedition against the valley of the Nile. The gathering of the army took years, and when in 373 all was ready, his attempt to force the passage of the Nile failed. A conflict with Iphicrates, the leader of the Greek mercenaries, increased the difficulties; at last Pharna- bazus led the army back to Asia, where these campaigns dated the end of his career. His biography is one of the chief sources of our knowledge of Pharnabazus in Aramaic writing. When he died is not known.

In the time of Alexander we meet with a Persian general Pharna- bazus, son of Artabazus (Arrian ii. 1 seq.), who probably was the grandson of the older Pharnabazus. This Pharnabazus was also borne by a king of Iberia (Georgia), on the Caucasus, where the dynasty seems to have been of Persian origin, defeated by a general of Marcus Antony (Mark Antony) in 36 b.C. (Dio Cass. xlix. 24). In the Georgian dynasty the name occurs as late as the 19th century. (Ed. M.)

PHARYNGITIS. The pharynx, or upper portion of the gullet (seen to a large extent on looking at the back of the mouth) is frequently the seat of a chronic inflammatory condition, usually associated with deflections of the digestive organs, or with syphilis or gout; sometimes it is due to much speaking or to excessive tobacco-smoking—especially of cigarettes. On inspection, the inflamed mucous membrane is seen unduly red and glazed, and dotted over with enlarged follicles. The condition produces considerable irritation and "dryness," with cough and discomfort, which may eventually become chronic. Treatment consists in removing all sources of irritation, in rectifying gastric disturbance, and in the application of the electric current, of astrigent lotions or of mild caustic solutions. The pain may be relieved by spraying with certain anodyne solutions. In the case of adenoid growths (see ADENOID) there is often an associated granular appearance of the pharyngeal membranes, so that the benign hypertrophied adenoid membranes are a common source of trouble.

The inflamed pharynx of the orator ("clergyman’s sore throat") may be put right by lessons in elocution or by complete rest for a time. The gouty throat may call for a change of diet, or for a stay at one of the watering-places where early rising, moderate food, regular exercise and the drinking of laxative waters join in restoring health. (E. O.*).
PHEASANT

The Bursa pharyngea was at one time looked upon as the place whence the pituitary body had been derived from the roof of the pharynx, but this is now disproved and its meaning is unknown. The tonsil is formed in the second branchial cleft or rather pouch, for the clefts are largely incomplete in man, about the fourth month; its lymphoid tissue, as well as that elsewhere in the pharynx, is formed from lymphocytes in the subjacent mesenchyme (see Embryology), though whether these wander in from the blood or are derived from original mesenchyme cells is still doubtful. The
devlopment of the ventral part of the pharynx is dealt with in the articles Tongue and Respiratory System.

Comparative Anatomy.—In the lower, water-breathing, vertebrates the pharynx is the part in which respiration occurs. The water passes in through the mouth and out through the gill slits where it comes in contact with the gills or branchiae.

The lowest subphylum of the phylum Chordata, to which the term Adelochorda is sometimes applied, contains a worm-like creature Balanoglossus, in which numerous rows of gill slits open from the pharynx, though Cephalodiscus, another member of the same subphylum, has only one pair of these.

In the subphylum Urochorda, to which the Ascidians or sea-squirts belong, there are many rows of gill slits, as there are also in the Acrania, of which Amphioxus, the lancelet, is the type. In all these lower forms there are no true gills, as the blood-vessels lining the large number of slits provide a sufficient area for the exchange of gases.

In the Cyclostomata a reduction of the number of gill slits takes place, and an increased area for respiration is provided by the gill pouches lined by pleated folds of endodermal mucous membrane;

these form the simplest type of true internal gills. In the larval lamprey (Amphicoelis) there are eight gill slits opening from the pharynx, but in the adult (Petromyzon) they are reduced to seven, and a septum grows forward separating the ventral or branchial part of the pharynx from the visceral or central part. Both these tubes, however, communicate near the mouth.

In fish there are usually five pairs of gill slits, though a rudimentary one in front of these is often present and is called the spiracle. Occasionally, as in the Herring and Haddock, there may be six or seven slits, and the evidence of comparative anatomy is that fishes formerly had a larger number of gill slits than at present.

In the Teleostomi, which include the bony fishes, there is an external gill cover or operculum.

In the Dipnoi or mud fish the work of the gills is shared by that of the lungs, and in the African form, Protopterus, external gills, developed from the ectodermal part of the gill slits, first appear. In the tailed Amphibians (Urodela) the first and fifth gill clefts are never perforated and are therefore in the same condition as all the gill clefts of the human embryo, while in the gilled salamanders (Necturus and Proteus) only two gill clefts remain patent. The gills in all Amphibia are external and of ectodermal origin, but in the Anura (frogs and toads) these are succeeded before the metamorphosis by internal gills, which, unlike those of fish, are said to be derived from the ectoderm.

In the embryos of the Sauropsida (reptiles and birds) five gill clefts are evident, though the posterior two are seldom at any time perforated, while in the Mammalia the rudiments of the fifth cleft are no longer found in the embryo, and in man, at all events, none of them are normally perforated except that part of the first which forms the Eustachian tube. It will thus be seen that in the process of phylogeny there is a gradual suppression of the gill clefts beginning at the more posterior ones.

The soft palate is first found in cyclostomes as a membraneous structure, and it becomes muscular in mammals. The bursa pharyngea and pharyngeal tonsil are found in several of the lower mammals. In the sheep the latter is particularly large.

For literature and further details, see R. Wiedersheim's Comparative Anatomy of Vertebrates, translated by W. N. Parker (London, 1907); also Parker and Haswell's Zoology (London, 1897).

PHEASANT (Mid. Eng. fesaut and fesant; Ger. fasan and anciently fasant; Fr. faisant—all from the Lat. phasianus or phasia, sc. avis), the bird brought from the banks of the river Phasis, now the Klion, in Colchis, where it is still abundant, and introduced, according to legend, by the Argonauts into Europe. Judging from the recognition of the remains of several species referred to the genus Phasianus both in Greece and in France, 1 it seems not impossible that the ordinary pheasant, the P. colchicus of ornithologists, may have been indigenous to this quarter of the globe. If it was introduced into England, it must almost certainly have been brought by the Romans; 2 for, setting aside several earlier records of doubtful authority, 3 Stubbs has shown that by the regulations of King Harold in 1059 unus phasianus is prescribed as the

1 These are P. orbiculati from Pomerania, P. altus and P. medius from the lacustrine beds of Sansan, and P. flavescens from Touraine, see A. Milne Edwards, Euxine et la Chine, (Paris, 1836), pp. 367, 368, whereas others, particularly the Phasianus of the Agarna, is gymnura, presumably of the age of Howel the Good, who died in 948. One of them is, "There are three barking hunts: a bear, a squirrel and a pheasant." The explanation is, A pheasant is called a barking hunt, because when the pointers come upon it and chase it, it takes to a tree, where it is hunted by baiting." The present writer has not been able to trace the manuscript containing these remarkable
PHEIDIAS

alternative of two partridges or other birds among the "pittantiae" (rations or commons, as we might now say) of the canons of Waltham Abbey, and, as W. B. Dawkins has remarked (Ibis, 1886, p. 358), neither Anglo-Saxons nor Danes were likely to have introduced it into England. It seems to have been early under legal protection, for, according to Dugdale, a licence was granted in the reign of Henry I. to the abbot of Amesbury to kill hares and pheasants, and from the price at which the latter are reckoned in 1169, we may be justified in assuming that in the very ancient eddars, they were very much in demand as food.

For several centuries, and also that they were occasionally artificially reared and fattened, as appears from Upton, 1 who wrote about the middle of the 17th century, while Henry VIII. seems from his privy purse expenses to have had in his household in 1532 a French priest as a regular "fessant breder," and in the accounts of the Kysts of Hengrave in Suffolk for 1607 mention is made of wheat to feed pheasants, partridges and quails.

The practice of bringing up pheasants by hand is now extensively followed, and the numbers so reared vastly exceed those that are bred at large. The eggs are collected from birds that are either running wild or kept in pens, and are placed under domestic hens; but, though these prove most attentive foster-mothers, much additional care on the part of their keepers is needed to ensure the arrival at maturity of the pouls; for, being necessarily crowded in a comparatively small space, they are subject to several diseases which often carry off a large proportion, to say nothing of the risk they run by not being provided with proper food, or by meeting an early death from various predatory animals attracted by the assemblage of so many helpless victims. As they advance in age the young pheasants readily take to a wild life, and indeed can only be kept from wandering in every direction by being plentifully supplied with food, which has to be scattered for them under the covers in which it is desired that they should stay. The proportion of pheasants artificially bred that "come to the gun" would seem to vary enormously, not only irregularly according to the weather, but regularly according to the district. In the eastern counties of England, and some other favourable localities, perhaps three-fourths of those that are hatched may be satisfactorily accounted for; but in many of the western counties, though they are the objects of equal or even greater care, it would seem that more than half the number that live to grow their feathers disappear inexplicably before the covers are beaten. For the sport of pheasant-shooting see SMORRER.

Formerly pheasants were taken in snares or nets, and by hawking; but the crossbow was also used, and the better to obtain a "sitting shot," 2-for with that weapon men had not learnt to "shoot flying"—dogs appear to have been employed in the way indicated by the lines under an engraving by Hollar, who died in 1677:

"The Peasant Cocket the woods doth most frequent, Where Spaniells spring and purchie him by the sent." 3

Of the many other species of the genus Phasianus, two only can be dwelt upon here. These are the ring-necked pheasant of China, P. torquatus, easily known by the broad white collar, whence it has its name, as well as by the pale greyish-blue of its upper wing-coverts and rump and the light buff of its flanks, and the P. versicolor of Japan, often called the green pheasant statements so as to find out the original word rendered "pheasant" by the translator; but a reference to what is probably the same passage in the translation of the Asinaria by Selden (Sylva, math. animalium, pp. 213, 214) on the authority of Llwyd or Lloyd, though there is no mention of it in Wotton and Clarke's Leges Walliacae (1730). A charter (Kemble, Cod. diplom. iv. 230), professedly of Edward, granting the wardship of certain forests in Essex to Ralph Peperling, speaks of "fessant hen" and "fessant cocke," but is now known to be spurious. In his De situ militari (see print 1545) he states (p. 195) that the pheasant was brought from the East by "Palladius antiquus."

1 Quoted by the writer (Broderip?) of the article "Spaniel" in the Penny Cyclopædia. The line "thow gow light on the asserterd Welsh practice mentioned" is a former note.

2 The citation from Plautus (Stultus castus) is found in Dods, Pat. Lit. i. 297, 298. The pheasant is called a "coccia" by many of the ancient writers.

3 Quoted by the writer (Broderip?) of the article "Spaniel" in the Penny Cyclopædia. The line "thow gow light on the asserterd Welsh practice mentioned" is a former note.

\[\text{PHEIDIAS, son of Charmides, universally regarded as the greatest of Greek sculptors, was born at Athens about 500 B.C. We have varying accounts of his training. Hegias of Athens, Ageladas of Argos, and the Thasian painter Polycnemus, have been named as his masters. In the work of Ageladas it may be said that the influence of the many Dorian statues is certainly to be traced in some of his work. Of his life we know little apart from his works. Of his death we have two discrepant accounts. According to Plutarch he was made an object of attack by the political enemies of Pericles, and died in prison at Athens. According to Philochorus, as quoted by a scholarist on Aristophanes, he fled to Elus, where he made the great statue of Zeus for the Eleans, and was afterwards put to death by them. For several reasons the first of these tales is preferable.}

Plutarch gives in his life of Pericles a charming account of the vast artistic activity which went on at Athens while that statesman was in power. He says that Pericles raised a fortune for the city the money furnished by the Athenian allies for defence against Persia: it is very fortunate that after the time of Xerxes Persia made no deliberate attempt against Greece. "In all these works," says Plutarch, "Pheidias was the adviser and overseer of Pericles." Pheidias introduced his own portrait and that of Pericles on the shield of his Parthenon statue. And it was through Pheidias that the political enemies of Pericles struck at him. It thus abundantly appears that Pheidias was closely connected with Pericles, and a ruling spirit in the Athenian art of the period. But it is not easy to go beyond this general assertion into details.

It is certain that the historians attribute the fame of Pheidias upon the sculptures of the Parthenon we proceed with little evidence. No ancient writer ascribes them to him, and he seldom, if ever, executed works in marble. What he was celebrated

for in antiquity was his statues in bronze or gold and ivory. If Plutarch tells us that he superintended the great works of Percies on the Acropolis, this phrase is very vague. On the other hand, inscriptions prove that the marble blocks intended for the pedimental statues of the Parthenon were not brought to Athens until 434 B.C., which was probably after the death of Phaidias. And there is a marked contrast in style between these statues and the certain works of Phaidias. It is therefore probable that most if not all of the sculptural decoration of the Parthenon was the work of pupils of Phaidias, such as Alcamenes and Agoracritus, rather than his own.

The earliest of the great works of Phaidias were dedications in memory of Marathon, from the spoils of the victory. At Delphi he erected a great group in bronze including the figures of Apollo and Athena, several Attic heroes, and Miltiades the general. On the Acropolis of Athens he set up a colossal bronze image of Athena, which was visible far out at sea. At Pellene in Achaea, and at Plataea he made two other statues of Athena, also a statue of Aphrodite in ivory and gold for the people of Elis. But among the Greeks themselves the two works of Phaidias which far outshine all others, and were the basis of his fame, were the colossal figures in gold and ivory of Zeus at Olympia and of Athena Parthenos at Athens, both of which belong to about the middle of the 5th century. Of the Zeus we have unfortunately lost all trace save small copies on coins of Elis, which give us but a general notion of the pose, and the character of the head. The god was seated on a throne, every part of which was used as a ground for sculptural decoration. His body was of ivory, his robe of gold. His head was of somewhat archaic type: the Otricoli mask which used to be regarded as a copy of the head of the Olympian statue is certainly more than a century later in style. Of the Athena Parthenos two small copies in marble have been found at Athens (see Greek Ant. fig. 38) which have no excellence of workmanship, but have a certain evidential value as to the treatment of their original.

It will be seen how very small is our actual knowledge of the works of Phaidias. There are many stately figures in the Roman and other museums which clearly belong to the same school as the Parthenos; but they are copies of the Roman age, and not to be trusted in point of style. A Furtwängler proposes to find in a statue of which the head is at Bologna, and the body at Dresden, a copy of the Lennian Athena of Phaidias; but his arguments (Masterpieces, at the beginning) are anything but conclusive. Much more satisfactory as evidence are some 5th century torsos of Athena found at Athens. The very fine torso of Athena in the École des Beaux Arts at Paris, which has unfortunately lost its head, may perhaps best serve to help our imagination in reconstructing a Phaidian original.

As regards the decorative sculptures of the Parthenon, which the Greeks rated far below their colossus in ivory and gold, see the article PARTHENON.

Ancient critics take a very high view of the merits of Phaidias. What they especially praise is the ethos or permanent moral level of his works as compared with those of the later "pathetic" school. Demetrius calls his statues sublime, and at the same time precise. That he rode on the crest of a splendid wave of art is not to be questioned: but it is to be regretted that we have no morsel of work extant for which we can definitely hold him responsible.

**PHEIDON** (8th or 7th century B.C.), king of Argos, generally, though wrongly, called "tyrant." According to tradition he flourished during the first half of the 8th century B.C. He was a vigorous and energetic ruler and greatly increased the power of Argos. He gradually regained sway over the various cities of the Argive confederacy, the members of which had become practically independent, and (in the words of Ephorus) "re-united the broken fragments of the inheritance of Temenus." His object was to secure predominance for Argos in the north of Peloponnesus.

According to Plutarch, he attempted to break the power of Corinth, by requesting the Corinthians to send him 1000 of their picked youths, ostensibly to aid him in war, his real intention being to put them to death; but the plot was revealed. Phaidon assisted the Pisatans to expel the Elean superintendents of the Olympic games and presided at the festival himself. The Eleans, however, refused to recognize the Olympic or to include it in the register, and shortly afterwards, with the aid of the Spartans, who are said to have looked upon Phaidon as having ousted them from the headship of Greece, defeated Phaidon and were reinstated in the possession of Pisatis and their former privileges. Phaidon is said to have lost his life in a faction fight at Corinth, where the monarchy had recently been overthrown. The affair of the games has an important bearing on his date. Pausanias (vi. 22, 2) definitely states that Phaidon presided at the festival in the 8th Olympiad (i.e. in 748 B.C.), but before the birth of the Persian Agariste, daughter of Cleisthenes of Sicyon, given by Herodotus, 11:2; and especially the name of Leocedes (Lacedas), son of Phaidon of Argos. According to this, Phaidon must have flourished during the early part of the 6th century. It has therefore been assumed that Herodotus confused two Phaidons, both kings of Argos. The suggested substitution in the text of Pausanias of the 28th for the 8th Olympiad (i.e. 668 instead of 748) would not bring it into agreement with Herodotus, for even then Phaidon's son could not have been a suitor in 570 for the hand of Agariste. But the story of Agariste's wooing resembles romance and has slight chronological value. On the whole, modern authorities assign his date about 630 B.C., according to Herodotus further states that Phaidon established a system of weights and measures throughout Peloponnesus, to which Ephorus and the Persian Chronicle add that he was the first to coin silver money, and that his mint was at Aegina. But according to the better authority of Herodotus (i. 94) and Xenophanes of Colophon, the Lydians were the first coiners of money at the beginning of the 7th century, and, further, the oldest known Aeginetan coins are of later date than Phaidon. Hence, unless a later Phaidon is assumed, the statement of Ephorus must be considered unhistorical. No such difficulty occurs in regard to the weights and measures; it is generally agreed that a system was already in existence in the time of Phaidon, into which he introduced certain changes. A passage in the Aristotelian Constitution of Athens (x. 2) states that the measures used before the Solonian period of reform were called "Pheidianian."

See Herodotus vi. 127; Ephorus in Strabo vili. 356, 376; Plutarch, Amatoriae narrationes, 2; Marmor parricus, ed. 30; Pollux ix. 83; Nicolaus Damascus, frag. 41 (in C. W. Müller's Frag. hst. graece, iii.); Grote, History of Greece, pt. ii. ch. 41 B. V. Head, History of the Anc. World (1886); F. Hultsch, Griechische und Römische Historiographie (1882); G. Rawlinson's Herodotus, appendix, bbl. i., note 8. On the question of Phaidon's date, see J. B. Bury, History of Greece 668 (1858); J. P. Mahoney, Problems of Greek History, ch. 3 (1892); J. G. Frazer's note on Pausanias vii. 22, 2; especially G. Busolt, Griechische Geschichte (2nd ed., 1803), ch. 12. C. Triebert, Pheidon von Argos (Hanover, 1880), and J. Beloch, in Rheinisches Museum, xiv. 595 (1890) favour a later date, about 580.

**PEPHLS, AUSTIN** (1830–1860), American Congregational minister and educationalist, was born on the 7th of January 1830 at West Brookfield, Massachusetts, son of Eliakim Phelps,1 a clergyman, who, during the boyhood of his son was principal of a girls' school in Pittsfield, Massachusetts, and later pastor of a Presbyterian church in Geneva, New York. The son studied at Hobart College in 1853–1855, then at Amherst for a year, and in 1857 graduated at the university of Pennsylvania. He studied theology at Union Theological Seminary, at the Yale Divinity School, and at Andover, and was licensed to preach in 1840 by the Third Presbytery of Philadelphia. He was pastor of the Pine Street (Congregational) Church in Boston in 1842–1845, and in 1846–1879 was professor of sacred literature at the theological Seminaries at which he was president from 1860 to 1879, when his failing health forced him to resign. He died on the 13th of October 1850 at Bar Harbor, Maine. His Theory of Preaching (1881) and English

1 Eliakim Phelps afterwards lived in Stratford, Herkimer county, New York, where his house was "possessed" and was long a place of curious interest to students of "spiritualism."
PHELPS, E. J.—PHENACETIN

Style in Public Discourse (1883) became standard textbooks; and personally he was a brilliant preacher. He married in 1832 Elizabeth Stuart (1815–1892), eldest daughter of Moses Stuart, then president of Andover; she was the author of the popular novel, The Sabbath Hymn (1859). In 1854 he married her sister, who died only eighteen months later; and in 1858 he married Mary A. Johnson, of Boston.

With Professors E. A. Park and D. L. Furber he edited Hymns and Choruses (1860), and with Professor Park and Lowell Mason The Sabbath Hymn Book (1859). The Still Hour (1859), a summary of a series of sermons on, with, or in defence of, the Kean. He was the third pastor at Burlington, Vermont, from 1851 to 1853. In this capacity, and after his death in 1857, when he returned to Burlington. Becoming a Democrat after the Whig party had ceased to exist, he was debarred from a political career in his own state, where his party was in the minority, but he served in the state constitutional convention in 1870, and in 1880 he was the Democratic candidate for governor of his state. He was one of the founders of the American Bar Association, and was its president in 1880–1881. From 1881 until his death he was Kent Professor of Law in Yale University. He was minister to Great Britain from 1885 to 1889, and in 1893 served as senior counsel for the United States before the international tribunal at Paris to adjust the Bering Sea controversy. His closing argument, requiring eleven days for its delivery, was an exhaustive review of the case. Phelps lectured on medical jurisprudence at the university of Vermont in 1885–1883, and on constitutional law at Boston University in 1882–1883, and delivered numerous addresses, among them that on “The United States Supreme Court and the Sovereignty of the People” at the centennial celebration of the Federal Judiciary in 1800 and an oration at the dedication of the Bennington Battle Monument, unveiled in 1891 at the centennial of Vermont’s admission to the Union. In politics Phelps was a labor leader and a socialreformer. When he retired before 1866, the free-silver movement in 1869, by contributing the Republican presidential ticket, and after 1898 becoming an ardent “anti-expansionist.” He died at New Haven, Connecticut, on the 5th of March 1900.

PHELPS, SAMUEL (1804–1878). English actor and manager, was born at Devonport on the 13th of February 1804. He was early thrown upon his own resources, and worked in various newspapers. Shortly after his marriage in 1826 to Sarah Cooper (d. 1867), he accepted a theatrical engagement in the York circuit at eighteen shillings a week, and afterwards appeared in south of England towns in prominent tragic roles, attracting sufficient attention to be spoken of as a rival to Kean. He made his first London appearance on the 28th of August 1837 as Shylock at the Haymarket. After a short season at the St. James’s Theatre with Macready for six years at Covent Garden, the Haymarket and Drury Lane successively. In 1844 he became co-lees of Sadler’s Wells Theatre with Thomas L. Greenwood and Mrs Mary Amelia Warner (1804–1854). Greenwood supplied the business capacity, Phelps was the theatrical manager, and Mrs Warner leading lady. In this position Phelps remained for twenty years, during which time he raised the Sadler’s Wells house to an important position, and himself appeared in a very extensive and varied repertory. Thirty-four of Shakespeare’s plays were presented there during his direction, with great educational effect, both on public and players. In 1861 Greenwood retired from the partnership, and Phelps, until 1867, conducted the business of management, retired from it in the following year. For the next fifteen years he acted under various managements, achieving considerable success in some of Halliday’s dramatic versions of Scott’s novels, such as The Fortunes of Nigel and Ivanhoe. His last appearance was in 1878 as Wolsey in Henry VIII., and he died on the 6th of November 1878. He was a sound and capable actor, rather than one of any marked genius; and, in spite of his predilection for tragedy, was most successful in such characters of comedy as called for dry humour. Perhaps Sir Pertinax Macscopyphon in Charles Macklin’s The Man of the World was his finest impersonation. He published an annotated edition of Shakespeare’s plays (2 vols., 1852–1854).

Phelypeaux, a French family of Bézéois. Its two principal branches were those of the signeurs of Herbaud, La Vrillière and Saint Florentin, and of the counts of Pontchartrain and Maurepas. Raimond Phelypeaux, seigneur of Herbaud and La Vrillière (d. 1629), was treasurer of the Épargne in 1599, and became secretary of state in 1621. His son Louis succeeded him in this latter office, and died in 1651. Balthazar Phelpeaux, marquis de Châtenuef (d. 1702), and Louis, marquis de La Vrillière (d. 1725), respectively son and grandson of Louis, were also secretaries of state. Louis Phelpeaux (1705–1777), count of Saint Florentin and afterwards duke of La Vrillière (1770), succeeded his father as secretary of state; became minister of the king’s household in 1749, a minister of state in 1751, and discharged the functions of minister of foreign affairs on the disgrace of Choiseul (1770). He incurred great unpopularity by his abuse of lettres de cachet, and had to resign in 1775. Raimond Balthazar Phelpeaux, seigneur du Verger, a member of the La Vrillière branch, was sent as ambassador to Savoy in 1700, where he discovered the intrigues of the duke of Savoy, Victor Amadeus II., against France; and when war was declared he was kept a close prisoner by the duke (1703–1704). At the time of his death (1731) he was governor-general in the West Indies. The branch of Pontchartrain-Maurepas was founded by Paul Phelpeaux (1560–1621), brother of the first-mentioned Raimond; he became secretary of state in 1610.

Phenacetin, C₈H₇O₃H₂N₃COCH₃ (para-acetaminophenol), a drug prepared by acetylation para-phenetidin, or by heating para-acetylaninophenol and potassium ethyl sulphate with alcoholic soda to 130°C. Para-phenetidin is prepared by treating the sodium salt of para-nitrophenol with ethyl iodide, and reducing the nitrophenol to para-phenetidin or aminophenol. The yield may be doubled by diazotizing para-phenetidin, coupling with phenol, ethylating and reducing: EtO-C₆H₄-NH₂→EtO-C₆H₄-N-OEt→EtO-C₆H₄-NH₂→EtO-C₆H₄-N-C₆H₄H₂OEt→2EtO-C₆H₄-NH₂

It crystallizes from water in colourless plates, melting at 135°C. It is soluble in about 70 parts of hot and in about 1400 parts of cold water.

Several compounds related to phenacetin have been introduced into medicine. Triphenin is propylphenetidin; lactophenin is lactyphenidetin; pyrantin is para-ethoxyphenyl succinimide, EtO-C₆H₄-N(COCH₃); salophen or salphen is salicylphenetidin; amydglophenin is mandellyphenetidin. In addition, several other derivatives have been suggested which have a greater solubility than phenacetin, e.g. phensin, which is the sodium salt of phenacetin sulphonic acid, apidyn and citrphenin, and salicylphenetidin (sulphonphenacetin), which are citric acid derivatives of para-phenetidin, &c.

Phenacetin is contained in both the British and United States pharmacopoeia, in the latter under the name of acetylphenetidin. The dose is 5 to 10 grs. given in cachets or in suspension. When the drug is carelessly made it may contain impurities, producing considerable irritation of the kidneys. The physiological action of phenacetin consists in a sedative action on the sensory tracts of the spinal cord, and a depressant action on the heart, where it
tends to paralyse the action of the cardiac muscle. Upon the bodily heat it exercises a marked effect, decreasing the action of the heat-producing centre as well as increasing the dissipation of heat, and thus causing a marked fall in temperature; and doses the blood becomes dark and blackish from the formation of methaemoglobin, and the urine is changed in colour from the passage of altered blood. The chief therapeutic use of phenacetin is as an antinociculig, and it is of service in migraine, rheumatism of the sub-acute type, intercostal neuralgia and locomotor ataxia.

PHENACITE, a mineral consisting of beryllium orthosilicate, Be$_3$SiO$_4$, occasionally used as a gem-stone. It occurs as isolated crystals, which are rhombohedral with parallel-faced habit, and are either lenticular or prismatic in habit; the lenticular habit is determined by the development of faces of several obtuse rhombohedra and the absence of prism faces (the accompanying figure is a plan of such a crystal viewed along the triad, or principal, axis). There is no cleavage, and the fracture is conchoidal. The hardness is high, being 7½-8; the specific gravity is 2-98. The crystals are sometimes perfectly colourless and adamantine, but more often they are greyish or yellowish and only translucent; occasionally they are pale rose-red. In general appearance the mineral is not unlike quartz, for which indeed it had been mistaken; on this account it was named, by N. Nordenstam in 1833, from Gr. φάκες (a deceiver).

Phenacite has long been known from the emerald and chrysoberyl mine on the Takovaya stream, near Ekaterinburg in the Urals, where large crystals occur in mica-schist. It is also found with topaz and amazon-stone in the granite of the Linn mountains in the southern Urals, and of the Pike's Peak region in Colorado. Large crystals of prismatic habit have more recently been found in a felspar quarry at Kragerø in Norway. Framont near Schirmeck in Alsace is another well-known locality. Still larger crystals, measuring 12 in. in diameter and weighing 28 lb, have been found at Greenwood in Maine, but these are pseudomorphs of quartz after phenacite.

For gem purposes the stone is cut in the brilliant form, of which there are two fine examples, weighing 43 and 34 carats, in the British Museum. The indices of refraction (ω = 1·5450, ε = 1·5627) are higher than those of quartz, beryl or topaz; a faceted phenacite is consequently rather brilliant and may sometimes be mistaken for diamond.

PHENACODUS, one of the earliest and most primitive of the ungulate mammals, typifying the family Phenacodontidae and the sub-order Condylarthra. The typical Phenacodus primacus, of the Lower or Wasatch Eocene of North America, was a relatively small ungulate, of slight build, with straight limbs each terminating in five complete toes, and walking in the digitigrade fashion of the modern tapir. The middle toe was the largest, and the weight of the body was mainly supported on this and the two adjoining digits, which appear to have been encased in hoofs, thus foreshadowing the tridactyl type common in perissodactyls and certain extinct groups of ungulates. The skull was small, with proportionately minute brain; and the arched back, strong lumbar vertebrae, long and powerful tail, and comparatively feeble fore-quarters all proclaim kinship with the primitive creodont Carnivora (see CREODONTA), from which Phenacodus and its allies, and through them the more typical Ungulata, are probably derived. All the bones of the limbs are separate, and those of the carpus and tarsus do not alternate; that is to say, each one in the upper row is placed immediately above the corresponding one in the row below. The full series of forty-four teeth was developed; and the upper molars were short-crowned, or brachyodont, with six low cones, two internal, two intermediate and two external, so that they were of the typical primitive bunodont structure. In habits the animal was cursorial and herbivorous, or possibly carnivorous.

In the Puerco, or Lowest Eocene of North America the place of the above species was taken by Euprologonia puercensis, an animal only half the size of Phenacodus primacus, with the terminal joints of the limbs intermediate between hoofs and claws, and the first and fifth toes taking their full share in the support of the weight of the body. These two genera may be regarded as forming the earliest stages in the evolution of the horse, coming below Hyracotherium (see EQUIDAE).

As ancestors of the Artiodactyl section of the Ungulata, we may look to the forerunners more closely related to the North American Lower Eocene genera Miochaenus and Pantocestes, respectively typifying the families Miochaeniidae and Pantocestidae. They were five-toed, bunodont Condylarthra, with a decided approximation to the perisodactyl type in the structure of the foot. A third type of Condylarthra from the North American Lower Eocene is represented by the family Meniscotheridae, including the genera Meniscotherium and Hyracops. These, it is suggested, may have been related to the ancestral Hyracoidae. Teeth and jaws probably referable to the Condylarthra have been obtained in European early Tertiary formations. All Ungulata probably originated from Condylarthra.

See H. F. Osborn, Skeleton of Phenacodus primacus; comparison with Euprologonia, Bull. Amer. Mus. x. 159.

PHENANTHRENE, C$_8$H$_{10}$, a hydrocarbon isomeric with anthracene, in which case it occurs in the fraction of the coal tar distillate boiling between 270°-400° C. It may be separated from the anthracene oil by repeated fractional distillation, followed by fractional crystallization from alcohol (anthracene being the less soluble), and finally purified by oxidizing any residual anthracene with potassium bichromate and sulphuric acid (R. Anschutz and G. Schultz, Ann., 1879, 106, p. 352; or the two hydrocarbons may be separated by carbon bisulphide, in which which anthracene is insoluble. It is formed when the vapours of toluene, stilbene, dibenzyl, ortho-ditolyl, or coumarone and benzene are passed through a red-hot tube by distilling morphine with zinc dust; and, with anthracene, by the action of sodium on ortho-benzylmethyl benzole (C. L. Jackson and J. F. White, Amer. Chem. Jour., 1886, 2, p. 391). It crystallizes in colourless plates or needles, which melt at 90° C. Its solutions in alcohol and ether have a faint blue fluorescence. When heated to 250° C. with red phosphorus and hydrobromic acid it gives a hydride C$_4$H$_7$H. It is nitrated by nitric acid and sulphuric acid. With picric acid it forms a sparingly soluble picrate, which melts at 153° C. On the condition of phenantrene in alcoholic solution see K. Behrend, Zeit. phys. Chem. 1890, 18, 1, 9, p. 405; 19, 9, 465. Chromic acid oxidizes phenantrene, first to phenanthrenequinone, and then to diphenic acid, H$_2$O.C$_6$H$_4$.C$_6$H$_4$.CO.H.

Phenantrene-quinone, [C$_6$H$_4$.C]$_2$O, crystallizes in orange needles which melt at 198° C. It possesses the characteristic properties of a diketone, forming crystalline derivatives with sodium bisulphite and a dioxide with hydroxylamine. It is non-volatile in steam, and is odourless. Sulphurous acid reduces it to the corresponding dihydroxy compound. It combines with ortho-di-amines, in the presence of acetic acid, to form phenantrazines.

On the constitution of phenantrene see CHEMISTRY: § Organic.

PHENAZINE (Azophenylene), C$_8$H$_7$N$_2$, in organic chemistry, the parent substance of many dyestuffs, e.g. the eurhdines, toluylene red, indulines and safranines. It is a dibenzopara- diazine having the formula given below. It may be obtained by distilling barium azobenzolata (A. Claus, Ber., 1873, 6, 742); by passing aniline vapour over lead oxide, or by the oxidation of dihydrophenazine, which is prepared by heating pyrocatechin with orthophenylenediamine (C. Ris, Ber., 1886, 19, p. 2206). It is also formed when ortho-aminodiphenyldiamine is distilled over lead peroxide (O. Fischer and E. Hepp). It crystallizes in yellow needles which melt at 171° C., and are only sparingly soluble in alcohol. Sulphuric acid dissolves it, forming a deep-red solution. The more complex phenazines, such as the naphthophenazines, naphthazines and naphtholotolazenes, may be prepared by condensing ortho-di-amines with ortho-quinones (O. Hinsberg, Ann., 1887, 237, p. 340); by the oxidation of an ortho-diamine in the presence of a-naphthol (O. Witt), and by
the decomposition of ortho-anilido-(touluidido- &c.)azo compounds with dilute acids. If alkyl or aryl-ortho-diamines are used azonium bases are obtained. The azines are mostly yellow in colour, dissolving unchanged and are stable to oxidants. They add on alkyl iodides readily, forming alkyl azonium salts.

By the extraction of amino or hydroxyl groups into the molecule dyestuffs are formed. The mono-aminodervatives or euridines are obtained when the arylamines are condensed with ortho-aminodervativs azo compounds; by condensing quinone dichlorides, para-nitrosodimethyl aniline with mounings containing a free para position, or by oxidizing ortho-hydroxydialminophenylamines (R. Nitzki, Ber., 1895, 25, p. 1207; O. Fischer, ibid., 1889, 29, p. 1874). They are yellowish-red solids, which behave as weak bases, their salts undergoing hydrolytic dissociation in aqueous solution. When heated with concentrated hydrochloric acid the amino group is replaced by the hydroxyl group and the phenolic euridines are produced.

The symmetrical diaminoazophenine is the parent substance of the important dyestuff toluylene red or dimethylaminothizophenazine. It is obtained by the oxidation of orthophenylene diam cine with ferric chloride; when a mixture of para-aminodimethylamino and meta-toluidylndiamine is oxidized in the cold, toluylene blue, an indamine, being formed as an intermediate product and passing into the red when boiled, and also by condensation of dimethylpara-phenylene diamine with metallocylene diamine. It crystallizes in orange-red needles and its alcoholic solution fluoresces strongly. It dyest black and mordanted cotton a fine scarlet. It is known commercially as Neutred Red. For the phenazenium salts see SAFRANINE.

Phenazine is an isomer of phenazine, with which it bears the same relation that phenanthrene bears to anthracene. It is formed by reducing the anilino group of benzthiazole in cold, by heating dilute alcohol, or by heating diphenylmine-ortho-dihydrazine with hydrochloric acid to 150° C. It crystallizes in needles which melt at 156° C. Potassium permanganate oxidizes it to pyridazine tetra-carboxylic acid.

\[
\text{Phenazine} \quad \text{Phenazone.}
\]

**PHENOLPHTHALEIN**. In organic chemistry, a compound derived from phthalophenone, or diphenyl phthalide (formula I), the anhydride of triphenyl-carbonil-ortho-carboxylic acid, which is obtained by condensing phthalyl chloride with benzene in the presence of aluminium chloride. The phthalides are formed from this anhydride by the hydroxyl or amino groups into the two phenyl residues, and are prepared by condensing phenols with phthalic anhydride, phenol itself giving rise to phenolphthalein (formula II) together with a small quantity of fluorane (formula III), whilst resorcin under similar conditions yields fluorescein (qv.). The phthalides on reduction yield phthalides, which are derivatives of triphenylmethane carboxylic acid; these reduction products are colourless and are employed in the leuco compounds of the phthalides, thus phenolphthalein itself gives phenolphthalein (formula IV).

Dehydrating agents usually convert the phenolphthaleins into anthraquinone derivatives.

\end{align*}
\]

Phenolphthalein is obtained when phenol and phthalic anhydride are heated with concentrated sulphuric acid. It crystallizes in colourless crystals which are not soluble in water, but dissolve in dilute solutions of the caustic alkalies with a fine red colour, being reprecipitated from these solutions by the addition of mineral acid. It dissolves in concentrated caustic alkalis to a colourless solution which probably contains salts of a non-quinnonoid character.

This difference in behaviour has led to considerable discussion (see H. Meyer, Monats., 1899, 20, p. 337; R. Meyer, Ber., 1903, 36, p. 1949; A. C. C. Lutke, Ber., 1894, 8, p. 339). On fusing with caustic alkali, phenolphthalein yields benzoic acid and para-dihydroxybenzophenone, which shows that in the original condensation the phthalic acid residue has taken the para position to the hydroxyl groups of the phenol.

Fluorane is a product of the condensation of the phthalic acid residue in the ortho position to the hydroxyl groups of the phenol, anhydride formation also taking place between these hydroxyl groups. It dissolves in concentrated sulphuric acid with a yellowish-green fluorescence. The rhodamines, which are closely related to the phthalides, are formed by the condensation of the alkyl meta-rhamines with phthalic anhydride in the presence of sulphuric acid. Their salts are fine red dyestuffs.

**PHENOMENON** (Gr. φαινόμενον, a thing seen, from φαίνειν, to appear), in ordinary language a thing, process, event, &c., observed by the senses. Thus the rising of the sun, a thunderstorm, an earthquake are natural "phenomena." From this springs the incorrect colloquial sense, something out of the common, an event which especially strikes the attention; hence such phrases as "phenomenal" activity. In Greek philosophy phenomena are the changing objects of the senses as opposed to essences (αδημοσια) which are one and permanent, and are therefore regarded as being more real, the objects of reason rather than of senses which are "bad witnesses." In modern philosophy the phenomenon is neither the "thing-in-itself" nor the noumenon (q.v.) or object of pure thought, but the thing-in-itself as it appears to the mind in sensation (see especially KANT; and METAPHYSICS). In this sense the subjective character is of prime importance. Among derivative terms are "Phenomenalism" and "Phenomenology." • Phenomenalism is either (1) the doctrine that there can be no knowledge except by phenomena, i.e. sense-given data, or (2) the doctrine that all known things are phenomena, i.e. that there are no "things-in-themselves." "Phenomenology" is the science of phenomena: every special science has a special section in which its particular phenomena are discussed; the term was first employed by Helm. in the 3rd edition of the Ency. Brit. in the article "Philosophy..." by J. Robison. Kant has a special use of the term for that part of the Metaphysics of Nature which considers motion and rest as predicates of a judgment about things.

**PHERECREATES**. Greek poet of the Old Attic Comedy, was a contemporary of Cratinus, Crates and Aristophanes. At first an actor, he seems to have gained a prize for a play in 438 B.C. The only other ascertained date in his life is 420, when he produced his play The Wild Men. Like Crates, whom he imitated, he abandoned personal satire for more general themes, although in some of the fragments of his plays we find him attacking Alcibiades and others. He was especially famed for his inventivc imagination, and the elegance and purity of his diction are attested by the epithet ἀρτύκωρος (most Attic) applied to him by Athenaeus and the sophist Phrynichus. He was the inventor of a new metre, called after him Pherecratian, which frequently occurs in the choruses of Greek tragedies and in Horace.

A considerable number of fragments from his 16 (or 13) plays has been preserved, collected in T. Kock, Complurum Atticorum Fragmenta, L. (1860), and A. Meineke, Positkum Comenium Graecorum Fragmenta, SS. (1855).

**PHERECYDES OF LEROS**. Greek mythographer, b. c. 454 B.C. He is probably identical with Pherecydes of Athens, although the two are distinguished by Suidas (also by I. Lipsius, Quaestiones logographicae, 1886). He seems to have been born in the island of Leros, and to have been called an Athenian because he spent the greater part of his life and wrote his great work there. Of his treatises, On Leros, On Iphiqeniae, On the Festivals of Dionysus, nothing remains; but numerous fragments of his genealogies of the gods and heroes, variously called Ταγώπα, Περακωλογία, Αρηυθώ, in ten books, written in the Ionic dialect, have been preserved (see C. W. Müller's Frag. hist. graec, vol. i. pp. xxxiv., 76). He modified the legends, not with a view to rationalizing them, but rather to adjust them to popular beliefs. He cannot, therefore, be classed with Hecataeus, whose method was far more scientific.

*See C. Lütke, Pherecydeia (diss. Göttingen, 1893); W. Christ, Geschichte der griechischen Literatur (1898); and especially H. Bertsch, Pherecydide Studies (1898).

**PHERE CYDES OF SYROS**, Greek philosopher (or rather philosophical theologian), flourished during the 6th century B.C. He was sometimes reckoned one of the Seven Wise Men, and is said to have been the teacher of Pythagoras. With the possible
exception of Cadmus (q.v.) of Miletus, he was the first Greek prose-writer. He belonged to the circle of Piseistratus at Athens, and was the founder of an Orphic community. He is characterized as "one of the earliest representatives of a half-critical, half-creduulous eclecticism" (Gomperz). He was credited with having originated the doctrine of metempsychosis (q.v.), while Cicero and Augustine asserted that he was the first to teach the immortality of the soul. Of his astronomical studies he left a proof in the "heliotropia", a cave at Syros which served to determine the annual turning-point of the sun, like the great "Heliotropos" (Posilippo, Posilippo) at Naples, and was once of the sights of the island.

In his cosmogonic treatise on nature and the gods, called Περίδοξος (Preller's correction of Suidas, who has έκτδοξος) from the five elementary or original principles (aether, fire, air, water, earth; Gomperz substitutes smoke and darkness for aether and earth), he eulogized a system in which science, allegory and mythology were blended. In the beginning were Chronos, the principle of time; Zeus (Zas), the principle of life; and Chthonion, the earth goddess. Chronos begat fire, air, and water, and from these sprang numerous other gods. Smoke and darkness appear in a later tradition. A fragment of the description of Mount Chthonion found on an Egyptian papyrus at the end of the 19th century.

See H. Diels, Fragmente der Vorsokратiker (1903); also O. Kern, De Orph. Epiceminiis, Pherecidas theogoniae (1888); D. Spiliotopoulos, Προς Γεωργίον τον Σωκό (Athen, 1890); T. Gomperz, Greek Thinkers (1906), Chapters 11, 12, 13; L. Gomperz, Α. Κ. Ρ., Προς Γεωργίον τον Σωκό (Athen, 1890).

PHIGALIA, or PHIGALEIA (Φιγαλεία or Φιγαλέια; mod. Patilio), an ancient Greek city in the south-west angle of Arcadia, situated on an elevated rocky site, among some of the highest mountains in the Peloponnesus—the most conspicuous being Mt Cotyllum and Mt Elasium; the identification of the latter is uncertain.

In 659 B.C. Phigalia was taken by the Lacedaemonians, but soon after its recovery its independence was maintained by the help of the Oristhians. During the struggle between Achacans and Aetolians in 221 B.C. it was held by Dorimachus, who left it on the approach of Philip V. of Macedon. In common with the other cities of Arcadia, it appears from Strabo to have fallen into utter decay under the Roman rule. Several curious cults were preserved near Phigalia, including that of the fish-tailed goddess Eurynome and the Black Demeter with a horse's head, whose image was renewed by Onatas. Notices of it in Greek history are rare and scanty. Though its existing ruins and the description of Pausania show it to have been a place of considerable strength and importance, no autonomous coins of Phigalia are known. Nothing remains above ground of the temples of Artemis or Dionysus and the numerous statues and other works of art which existed at the time of Pausania's visit, about A.D. 170. A great part of the city wall, built in fine Hellenic masonry, partly polygonal and partlyisosomous, and a large square central fortress with a circular projecting tower, are the only remains now traceable—at least without the aid of excavation. The walls, once nearly 2 m. in circuit, are strongly placed on rocks, which slope down to the little river Neda.

One very important monument still exists in a fairly perfect state; this is a temple dedicated to Apollo Epicurius (the Preserver), built, not at Phigalia itself, but at Bassae, 5 or 6 m. away, on the slope of Mt Cotyllum; it commemorates the aid rendered by Apollo in stopping a plague which in the 5th century B.C. was devastating Phigalia. This temple is mentioned by Pausanias (viii. 44) as being next (to that of Teges) the finest in the Peloponnesus. "From the beauty of its stone and the symmetry of its proportions." It was designed by Iktinus, who, with Callixrates, was joint architect of the Parthenon at Athens. Though visited by Chandler, Dodwell, Gell, and other English travellers, the temple was neither explored nor measured till 1811-1812, when C. R. Cockerell and some other archaeologists spent several months in making excavations there. After nearly fifty years' delay, Professor Cockerell published the results of these labours, as well as of his previous work at Aegina, in Temples of Aegina and Bassae (1860), one of the most careful and beautifully illustrated archaeological works produced. The labours of Cockerell and his companions were richly rewarded; not only were sufficient remains of the architectural features discovered to show clearly the whole design, but the internal sculptured frieze of the cella was found almost perfect. This and other fragments of its sculpture are now in the British Museum. The colonnade of the temple has been recently restored by the Greek authorities.

This plan shows the western example, which is of the Doric order, and has an internal arrangement of its cella unlike that of any other known temple. It stands on an elevated and partly artificial plateau, to which commands are given by the broken nature of the oak-clad mountains of Arcadia, reaching away to the blue waters of the Messenian Gulf. Unless the Doric temple usually stand east and west, this is placed north and south; but it has a side entrance on the east. It is however distinguished by having its halves on its flanks; thirty-four of the thirty-eight columns of the peristyle are still standing, with the greater part of their architectural features. Only two columns of the entablature and both pediments have fallen, together with the fragments of the frieze of the cella, which are of the cella. It will be seen from the plan that these are very strangely placed, apparently without symmetry, as regards the number of columns, though they are set regularly opposite the voids in the peristyle.

With the exception of one at the south end, which is Corinthian, the internal columns are of the Ionic order, and are engaged with the cella-wall, forming a series of recesses, which may have been intended to contain statues. Another peculiarity of this interior is that these columns reach to the top of the cella and in one order, namely those of columns, one over the other, as was the usual Doric fashion. These inner columns carried an entablature, of which the frieze now in the British Museum formed a part. The pediments and external metopes of the peristyle appear to have been removed not long after the destruction of the temple, and on the exterior of the cella had sculptured figures; only a few fragments of these were, however, discovered. The position occupied by the great statue of Apollo is a difficult problem. Cockerell, with much foresight, places it on the north side of the cella, which is the eastern side of the temple, so that it would be lighted up by the rays of the rising sun. The main entrance is at the northern end through the pronao, once defended by a door in the end of the cella and a metal screen, of which traces were found on the two columns of the pronao. There was no door between the posticum and the cella. The general proportions of the fronts resemble those of the Theseum at Athens, except that the entablature is less massive, the columns thicker, and the diminution less—all proportionally speaking. In plan the temple is long in proportion to its width—measuring, on the top of the stylobate, 125 ft. 7 in. by 48 ft. 2 in., while the Theseum (built probably half a century earlier) is about 104 ft. 2 in. by 45 ft. 2 in.

One of the materials of which the temple is built is a fine grey limestone (once covered with painted stucco), except the roof-tiles, the capitals of the cella columns, the architraves, the lacunaria (ceilings) of the pronao, the sculptured frieze, and the sculpture, all of which are of white marble. The roof-tiles were removed by Pausianias, are remarkable for their size, workmanship, and the beauty of the Parian marble of which they are made. They measure 2 ft. 1 in. by 3 ft. 6 in., and are fitted together in the most careful and ingenious manner. Unlike those of the Parthenon and the temple of Aegina, the ίσης or "joint-tiles" are worked out of the same piece of marble as the flat ones, for the sake of more perfect fitting and greater security against wet. Notwithstanding the great number of architectural members found by Cockerell, but they were too much faded for the colours to be distinguished. The designs are the usual Greek patterns—the fret, the honeysuckle, and the egg and dart.

There is a theory that the temple being designed to decorate one of the finest buildings in the Peloponnesus in the latter half of the 5th century B.C.; see Brit. Mus. Catalogue of Sculpture, vol. I.

The frieze, now in the British Museum, is complete; it is nearly 103 ft. long by 2 ft. high, carved in relief on twenty-three slabs of marble 4½ to 5 in. thick. The subjects are the battle of the Lapithae and the Centaurs, and that between the Amazons and the Greeks, the
two favourite subjects in Greek plastic art of the best period. They are designed with wonderful fertility of invention, and life-like realism of execution, so that the composition arranged so as to form a series of diagonal lines or zigzags, this is properly a pleasing extension to the unbroken horizontal lines of the cornice and architrave. The various groups are skilfully united together by some dominant line of action, so that the whole subject forms one unbroken composition.

The relief is very high, more than 3½ in. in the most salient parts, and the whole treatment is quite opposite to that of the Parthenon frieze. The sculptor, both in work and conception at Athens, has a very superior sense of the beauty of the whole, and the parts are but the necessary details. The limits of the limbs are quite detached from the ground; the drill has been largely used to emphasize certain shadows, and in many places, for want of due calculation, the sculptor has had to cut into the flat background behind the figures. From this it would seem that a finished clay-model was prepared, but that the relief was sculptured with only the help of a drawing. The point of sight, more than 20 ft. below the level of the frieze, and the direction in which the light fell on it have evidently been carefully considered. Many parts, invisible from below, are left comparatively rough. The workmanship throughout is unequal, and the hands of several sculptors can be detected.

On the whole, the execution is not equal to the beauty of the design, and the whole frieze is somewhat marred by an evident desire to produce the maximum of effect with the least amount of labour—very different from the almost gem-like finish of the Parthenon frieze. Even the design is inferior to the Athenian one; most of the figures are ungracefully short in their proportions, and there is a great want of refined beauty in many of the female hands and faces. It is in the fire of its varied action and interest that this sculpture most excels. The noble movements of the heroic Greeks form a striking contrast to the feminine weakness of the wounded Amazons, or the struggles with the heads and hoofs of the braying centaurs; the group of Apollo and Artemis in their chariot is full of grace and dignity, but vigorous. The marble in which this frieze is sculptured is somewhat coarse and crystalline; the slabs appear not to have been built into their place but thrown haphazardly, with the aid of two bronze bolts driven through the face of each.

Of the metopes, which were 2 ft. 8 in. square, only one exists nearly complete, with eleven fragments; the one almost perfect has a relief of a nude warrior, with floating drapery, overcoming a long-haired bearded man, who sinks vanquished at his feet. The relief of these is rather less than that of the frieze figures, and the work is nobler in character and superior in execution.

The name of the building is, see Leake, Morea (i. 490 and ii. 319); Curtius, Peloponnesos, i. 319; Ross, Reisen in Peloponnesos; Stackelberg, Der Apollo-Tempel zu Bassae (1826); Lenormant, Bas-reliefs du Parthenon et de Phigaleia (1834); and Histories of Sculpture mentioned under GREEK ART.

PHILADELPHIA, the Greek name (i) of a city in Palestine in the land of Ammon (see AMMONITES), and (2) of a city so-called in honour of Attalus II. of Pergamum, the modern Ali-Shaer (q.v.).

PHILADELPHIA, the third city in population in the United States, the chief city of Pennsylvania, and in the port of entry, co-extensive with Philadelphia county, is situated on the Delaware river beyond the Schuylkill River, and from below the confluence of the Delaware and Schuylkill rivers N.E. about 23 m. along the Delaware river and Poquessing Creek. Independence Hall, which is a few squares east by south of the city hall, is in 39° 56' 57.5" N. and 75° 8' 54.75" W. The port is about 102 m. from the Atlantic Ocean, and the city hall is 90 m. by rail S.S.W. of New York and 135 m. N.E. of Washington. The city has an area of 132.7 sq. m. At the southern extremity are lowlands protected by dikes from the tide; the business centre between the rivers is about 40 ft. higher but level; the district south of the Schuylkill is generally rolling; and in the upper district the surface rises from the Delaware northward to the north-west until in the extreme north-west a picturesque district overlooking Wissahickon Creek from hills exceeding 400 ft. in height.

Population.—When the first United States census was taken, in 1790, Philadelphia was the second largest city in the Union, and had a population of 28,522. It held this rank until 1830, when it was exceeded in size by Baltimore as well as by New York. In 1830 it was smaller also than Boston; but in 1854 the Consolidation Act extended its boundaries so as to include all Philadelphia county and in 1860 the city had risen again to second rank. This rank it held until 1890 when, although its population had grown to 1,266,964, it was 59,000 less than that of Chicago. In 1900, with a population of 1,393,679, it was still farther behind both New York and Chicago. In 1900, of the total population, 998,357, or 77.18% were native-born, as against only 65.7% native-born in New York and 65.43% native-born in Chicago. Of Philadelphia's native-born white population, however, 414,903, or 44.24%, were of foreign-born parentage. The foreign-born population included 98,367 born in Ireland, 71,319 born in Germany, 36,752 born in England, 28,951 born in Russia (largely Hebrews), 17,830 born in Italy, 8,479 born in Scotland and 51,54 born in Austria; and the coloured consisted of 62,613 negroes, 1165 Chinese, 235 Indians and 12 Japanese. In 1910 the population was 1,549,608.

The streets—With the exception of a limited number of diagonal thoroughfares and of streets laid out in outlying districts in conformity with the natural contour of the ground the plan of the city is regular. Market Street—which Penn called High Street—is the principal thoroughfare east and west, Broad Street the principal thoroughfare north and south, and these streets intersect at right angles at City Hall Square in the business centre. The streets parallel with Broad are numbered from First or Front Street west from the Delaware River to Thirty-Third Street, taking the prefix "North" north of Market Street and the prefix "South" south of it; the streets parallel with Market are named mainly from trees and from the governors and counties of Pennsylvania.

The wholesale district is centred at the east end of Market Street near the Delaware river. The best retail shops are farther west on the south side of Chestnut Street and on Market and Arch streets. Most of the leading banks and trust companies are on Chestnut Street and on Third Street between Chestnut and Walnut streets. Several of the larger office buildings and the stations of the Pennsylvania and the Philadelphia & Reading railways are in the vicinity of the city hall; here too, are the Baldwin Locomotive Works. The large textile mills, the great coal wharves and the Cramp Ship-Yards are to the north-east along the Delaware and in districts west of these are the leading manufacturers of iron and steel. There are large sugar refineries in the south-eastern part of the city. Rittenhouse Square, a short distance south-west of the city hall, is the centre of the old aristocratic residential district, and the south side of Walnut Street between Fourteenth and Nineteenth streets is a fashionable parade. There are fine residences on North Broad Street and on some of the streets crossing it, and many beautiful villas in the picturesque suburbs of the north-west. The most congested tenements, occupied largely by Italians, Hebrews and negroes, are along the alleys between the rivers and south of Market Street, often in the rear of some of the best of the older residences.

The principal structure is the city hall (or "Public Buildings") one of the largest buildings in the world in ground space (11 acres). It rises 548 ft. to the top of a colossal bronze statue (37 ft. high) of William Penn (by Alexander Calder) surmounting the tower. It accommodates the state and county courts as well as the municipal and county offices. The foundation stone was laid in August 1872. On its first floor is Joseph A. Bailly's statue of Washington, which was erected in front of Independence Hall in 1869. About the Public Buildings are statues of Generals McClellan and Reynolds, President McKinley, and Joseph Leidy and St Gaudens' "Pilgrim." On all sides are great buildings: on the northerly masonic temple (1868-1873); on the south the stately Betz Building; on the west the enormous Broad Street station of the Pennsylvania railway. The Pennsylvania Academy of Fine Arts and the Oddfellows' Temple are among other notable buildings in the vicinity. The post office, facing Ninth Street and extending from Market Street to Chestnut Street, was opened in 1884; in front is a seated statue of Benjamin Franklin, by John J. Boyle. The mint is at the corner of Sixteenth and Spring Garden streets. The custom-house, on Chestnut Street, was designed by William Strickland (1787-1854); in his day the leading American architect. It was modelled after the Parthenon of Athens, was built for the Second United States Bank, was completed in 1824, and was put to its present use in 1845. Other prominent buildings of
which Strickland was the architect are the stock exchange, St Paul's Protestant Episcopal Church, St Stephen's Church, the almshouse and the United States Naval Asylum. The main building of Girard College (on Girard Avenue, between North 19th and North 25th streets), of which Thomas Ustick Walter (1804-1887), a pupil of Strickland's, was the architect, is one of the finest specimens of pure Greek architecture in America. Near the Schuykill River, in West Philadelphia, are the buildings of the university of Pennsylvania. Its free museum of science and art, at South 23rd and Spruce, on the opposite side of the river, was built from the designs of Walter Cope, Frank Miles Day and Wilson Eyre, and its north-western part was first opened in 1890. Tall steel-frame structures, of which the Betz Building, completed in 1893, was the first, have become numerous. The Roman Catholic Cathedral of St Peter and St Paul, east of Logan Square, was begun in 1846 and was eighteen years in building. The Arch Street Methodist Episcopal Church is one of the most handsome churches in the city. The South Memorial Church of the Advocate (1897), on North 18th and Diamond streets, is a reproduction on a smaller scale of Amiens Cathedral.

Perhaps the most famous historical monument in the United States is Independence Hall, on Chestnut Street between Fifth and Sixth streets, designed for the state house by Andrew Hamilton (c. 1676-1741), speaker of the assembly, and was used for that purpose until 1799. The foundations were laid in 1731 and the main building was ready for occupancy in 1735, although the entire building was not completed until 1751. The steeple was taken down in 1774 but was restored by Strickland in 1828, and further restorations of the building to its original condition were effected later. In the east room on the first floor of this building the second Continental Congress met on the 10th of May 1775. George Washington was chosen commander-in-chief of the Continental army on the 19th of June 1775, and the Declaration of Independence was adopted on the 4th of July 1776. The room contains much of the furniture of those days, and on its walls are portraits of forty-five of the fifty-six signers of the Declaration and a portrait of Washington by Peale. At the head of the stairway is the famous Liberty bell, which bears the inscription, "Proclaim liberty through all the land unto all the inhabitants thereof" and is supposed (without adequate evidence) to have been the first bell to announce the adoption of the Declaration of Independence. It was cast in England in 1752, was cracked soon after it was brought to America, was recast with more copper in Philadelphia, and was cracked again in 1835 while being tolled in memory of Chief Justice John Marshall, and on the 22nd of February 1843 this crack was so increased as nearly to destroy its sound. On the second floor is the original of the charter which William Penn granted to the city in 1701 and the painting of Penn's treaty with the Indians by Benjamin West. The building has been set apart by the city, which purchased it from the state in 1816, as a museum of historical relics. On the north-west corner of Independence Square is old Congress hall, in which Congress sat from 1790 to 1800, and in which Washington was inaugurated in 1789 and 1793. A few steps to the west is the old city-hall, on the second floor of which the Supreme Court of the United States sat from 1791 to 1903. A short distance east of Independence Square in Carpenters' Hall, in which the first continental congress assembled on the 5th of September 1774 and in which the national convention in 1787 framed the present constitution of the United States; the building was also the headquarters of the Pennsylvania committee of correspondence, the basement was used as a magazine for ammunition during the War of Independence, and from 1791 to 1797 the whole of it was occupied by the First United States Bank. The Carpenters' Company (established in 1724) erected the building in 1770, and since 1857 has preserved it wholly for its historic association. On 19th Street near the Delaware is preserved as a national monument the house in which Betsy Ross, in 1777, made what has been called the first United States flag, in accordance with the resolution of Congress of the 14th of June. Not far from this house is Christ Church (Protestant Episcopal), a fine colonial edifice designed mainly by Dr John Kearsley (1684-1772). The corner stone was laid in 1727, but the steeple, in part designed by Benjamin Franklin and containing a famous chime of eight bells, was not completed until 1754. The interior was restored to its ancient character in 1883; the pews are painted in the American flag and the prominent位置 plate presented to the church by Queen Anne in 1708 is used on great occasions. In the churchyard are the graves of Benjamin Franklin, Robert Morris, Brigadier-General John Forbes, John Penn, Peyton Randolph, Francis Hopkinson and Benjamin Rush. St Peter's, the second Protestant Episcopal Church in the city, has a massive tower and a simple spire; within are the original pews. In the south-east part of the city near the Delaware is the ivy-clad Old Swedes' Church, built of brick in 1696-1706. The house which William Penn built about 1683 for his daughter Letitia was removed to Fairmount Park and rebuilt in 1883. In Germantown (q.v.), a suburb which was annexed in 1854, are several other historic buildings.

The dominant feature of the domestic architecture is the long rows, in street after street, of plain two-storey or three-storey dwellings of red ("Philadelphia") pressed brick with white marble steps and trimmings, and with white or green shutters, each intended for one family.

Parks.—Fairmount Park extends along both banks of the Schuylkill for about 5 m. and from the confluence of the Schuylkill and Wissahickon Creek it continues up the latter stream through a romantic Glen for 6 m. Its area is about 3418 acres. Five acres of an estate belonging to Robert Morris during the War of Independence and known as "Fair Mount," or "The Hills," were purchased by the municipality for a city waterworks and for park purposes in 1812, and from this beginning the park grew to its present dimensions. The first public buildings of any importance were the birth-place of David Rittenhouse, the astronomer, and a monastery of the German pietists, both on the banks of Wissahickon; and memorial hall and horticultural hall, both survivals of the centennial exhibition of 1876. On Lemon Hill, near the south end of the park, stands the Robert Morris mansion; in the vicinity is the cabin which was General U. S. Grant's headquarters at City Point, Virginia, during the winter of 1864-1865. Near the Columbia Avenue entrance to the park near the Schuylkill are the South street, the children's playground and playground, endowed by the will of Mrs Sarah A. Smith (d. 1895). At the Green Street entrance is an impressive monument to Augustus St Gaudens, designed by Rudolph Siemer and erected by the City of Cincinnati in 1896-1897, with a bronze equestrian statue. The Smith Memorial entrance, white granite with bronze statues, was erected in memory of the officers and men who fell in the Civil War. The Girard Park was purchased by Randolph Rogers; an equestrian statue of Grant by Daniel Chester French and Edward C. Porter; an equestrian statue of Major-General James Gordon Meade by Alexander Milne Calder; an equestrian statue of the Gift of the City of Philadelphia, an heroic bust of James A. Garfield by Augustus St Gaudens; statues of Columbus, Humboldt, Schiller and Goethe; a "Tann O' Shanter group of four figures in red sandstone by James Thom; John J. Boyle's "Stone Age in America"; Cyrus Edwin Dallin's "Medicine Man"; Wilhelm Wolff's "Wounded Lioness" (at the entrance to the Zoological Gardens); Albert Wolff's "Lion Fighter"; Auguste Nicolas Cain's "Lioness bringing a Wild Boar"; "Cuba Lion" by Myron; "Joan of Arc" by Edwin D. Dallin; "Frederick Remington's "Cow Boy"; and several artistic fountains, and a Japanese temple-gate. In the down-town district, Franklin, Washington, Rittenhouse and Logan squares are surrounded by public parks from the founding of the city: In Rittenhouse Square is the bronze "Lion and Serpent" of A. L. Barye. In Clarence H. Clark Park, West Philadelphia, is Frank Edwin Wood's "Dawn"; Thomas J. Hoppin's "Dawn"; "Dawn" by Adolph Weinman. The Garden streets opposite the Baldwin Locomotive Works is Herbert Adams's statue of Matthias William Baldwin (1795-1866), founder of the works. Close to the bank of the Delaware, some distance from the city, is the Great Elm tree under which the Indians in 1683. In the south-east part of the city, along the Schuylkill, is Bartram's botanical garden (57 acres).
PHILADELPHIA

369

added to its park system in 1891; in it is the stone house, with ivy-covered walls, which the famous botanist built with his own hands. Through the efforts of the City Park Association, organized in 1882, several triangular or circular parks, have been placed on the city plan. Among these are League Island Park (300 acres), opposite the United States navy yard on League Island; Penny Pack Creek Park (above, p. 428); and Rittenhouse Square north-east; Cobb's Creek Park, extending about 4 m. along the western border; Fairmount Parkway, 300 ft. wide on a direct line south-east from Fairmount Park to Logan Square and somewhat narrower from that point to the Delaware River. In 1839, 300 ft. wide and 103 m. long, from Hunting Park, 48 m. north of the city hall, along a direct line north-east to the city limits. A plaza at the intersection of Broad and John Street, radiating streets through the center of the Fairmount Park area, from plaza to League Island Park are also on the city plan. Laurel Hill cemetery, on a high bank of the Schuylkill and contiguous to Fairmount Park's private hunting ground; in it are the tombs of Dr. Elisha Kent Kane, the Arctic explorer, and Major General Meade.

Theatres.—The first Shakespearean performance in the United States was probably at Philadelphia in 1749; another company played there in 1754 and 1759; and in 1766 was built the Old Southwark theatre, in which Major John André and Captain John Peter De Lancey acted during the British occupation of the city, and which after twenty years of illegal existence was opened "by authority" in 1789. The Walnut Street theatre (1808) is said to be the oldest play-house in the United States. Other theatres are the Garrick, the large Academy of Music, the Chestnut Street opera house, the Lyceum, the Franklin, and the Fairmount Park and Franklin Clubs.

Clubs.—Among social clubs are the Union League, the University (1818), the Philadelphia, the City, the Markham, the Manufacturers (1827), the Commercial, the Lawyers, the Clover, the Pen and Pencil, the Art, the Mercantile, several confraternities (notably the Racket), and the foremost cricket clubs in the United States, the Belmont, the Philadelphia, the Keystone, the Merion (at Havertford), and the Germantown (at Manheim).

Museums, Learned Societies and Libraries.—In the southern part of Fairmount Park is a zoological garden with an excellent collection. Its site is the former estate of John Penn, grandson of William Penn. The University of Pennsylvania, one of the foremost of the United States, opened by Charles Willson Peale in Independence Hall in 1802. It is now owned by the Zoological Society (incorporated in 1859) and was opened in 1875. Other museums in Fairmount Park are the Willson Peale, and the Rosenbach collections. In the Academy hall the general art collections of the Pennsylvania Museum and School of Industrial Arts and the Wistar collection of paintings (about 300), including examples of the Italian school from the 15th to the 17th centuries and of modern French and American painters. Bartram's botanical garden, mentioned above as a city park, was established in 1728 by John Bartram (1699-1777) and is the oldest botanic garden in America. The Philadelphia Commercial Museum, founded in 1894, is a notable institution for the foreign commerce of the United States, having a collection of raw materials and manufactured products from all countries, a laboratory in which experiments are made, and a library with pamphlets and reports on the requirements and the requirements of markets in all parts of the world, maintains a bureau of information, issues a weekly bulletin for American exporters and a monthly publication for foreign buyers, and has a section of the "Atlantic trade," fore-forestry and commercial works. The museum is maintained chiefly by municipal appropriations and by fees. Its control is vested in "The Board of Trustees of the Philadelphia Museums," composed of fourteen citizens of Philadelphia chosen for life and eight ex officio trustees, who are the incumbents of the leading state and municipal offices. There are home and foreign advisory boards, and the immediate management is under a director. In 1727, Franklin, then in his twenty-third year, went to London "to be a bookseller," which he called the Junto, "for mutual improvement," and out of the Junto grew in 1731 the library of the Library Company of Philadelphia, which he spoke of as "the mother of all North American Library Companies." In 1894, a new edition of the classification book was published. In 1897, the Library Company of Philadelphia absorbed in 1760 the Union Library, which had been founded in 1736 by a group of local merchants, the first valuable collection of classical and other works provided for under the will of James Logan, a friend of Penn, was transferred to it. Subsequently it acquired by bequest the libraries of the Rev. Samuel Proctor, the Rev. Dr. John Kearsley, and William Wells. Among the rarities in the latter was a copy of Caxton's Golden Legend (1486). In 1869 the Library Company was made the beneficiary, under the will of Dr. James Rush (1786-1866), of an estate of 18 acres near the present Library on the Ridgeway branch was established in 1878. The library has owned its building since 1790; the building on the present site was opened in 1898 and was enlarged in 1899.

The American Philosophical Society, founded by Franklin in 1743, is the oldest and the most famous academy of science in America. Its organization was the immediate consequence of a circular by Franklin entitled, A Proposal for Promoting Useful Knowledge among the British Plantations in America. In 1769 it united with (and officially took the name of) "The American Society held at Philadelphia for Promoting Useful Knowledge." Among its early presidents were Dr. Benjamin Franklin and James Bowdoin, the last an efficient and valuable library—about 50,000 vols.—containing the great mass of the correspondence of Franklin; here, too, are many interesting relics of his contemporaries, the "papers of the Franklin family collected by Mr. Logan," by order of the Declaration of Independence and an autograph copy of the Declaration. The society has published 27 quarto vols. of Transac-

The American Academy of Sciences of Philadelphia, founded in 1812, has been a forerunner of the organization of its collections of shells and the "types" of Leidy, Cope, Say, Conrad and other naturalists, and a library. It is composed of the following departments: geological, (1876), botanical, (1876), mineralogical and geological (1877) and ornithological (1891). It has published a Journal since 1817 and its Proceedings since 1841, and periodicals on entomology, zoology and other subjects. To a few young men and women it gives training in scientific investigation without charge. The Pennsylvania Historical Society, organized in 1824, has a valuable collection of historical material, including the papers of the Penn family and the Charlemagne Tower collection of American colonial laws, and many early American printed handbills and books (especially of Bradford, Franklin and Christopher Saur), portraits and engravings. The Philadelphia Library Company, which has published its Proceedings. The College of Physicians and Surgeons has an excellent medical library. The free library of Philadelphia (established 1891) includes a good library and several branches. Other important libraries are the Special Library of the Pennsylvania State Library, the Mercantile, that of Franklin Institute, that of the Law Associa-

Among the noted collections of the Pennsylvania Museum and School of Industrial Arts are the first collections of the first botanical and the American and the Babylonian collections made by university expeditions.

Schools.—The frame of government provided for a committee of committees, education and art. The assembly, in March 1683, passed an act which provided that all children should be taught to read and write by the time they were twelve years of age, that then they should be taught some useful trade, and that for every child not so taught the parent or guardian should be fined five pounds. At a meeting of the provincial council held in Philadelphia in 1683 the governor and council appointed as schoolmasters, David Matthews and Stephen Pack. The latter had a school in England. But schools were left almost wholly to private initiative until 1818. The first grammar school, commonly known in the state as the "grammar school," was opened in 1689 under the care of the celebrated George Keith; although maintained by the friends it was open to all, and for more than sixty years was the only public place for free instruction in the province. It was rechartered by the General Assembly in 1749 as the Forthe known as the William Penn Charter School and is still a secondary school on Twelfth Street. In 1740 a building was erected for a "charity school" and for a "house of worship," but the school had to be closed in 1759, when, in 1739, Franklin published his Proposal relating to the Education of Youth in Pennsylvania. Under the influence of this publication a new educational association was formed which purchased the building and in January 1751 opened it in the building which was subsequently known as the "William Penn School" in 1753, was rechartered as a college and academy in 1755, and became the university of Pennsylvania by act of the state legislature passed in 1771. The university occupied the site of the present college buildings until 1846, when it opened the "academy of the new country" on the eastern bank of the Delaware River, and then returned to the former site near the western bank of the Schuylkill.

The foundation of the present public school system was laid in 1748, when the Provincial Congress, by act of October 3, provided for the establishment of one free school in each of the five counties of Pennsylvania the first school district of Pennsylvania and provided for the establishment therein of free schools for indigent orphans and the children of indigent parents; the same act also authorized the extension of the school system of Williamsburg, Virginia, which was the pioneer school for this purpose in America. In 1834 free elementary schools were authorized for all children of school age, and since then the system has developed until it embraces the Elementary School of the city of Philadelphia, with a department of pedagogy and confers the degrees of B.A. and B.S.; a Normal High School for girls, into which the model school was converted in 1848, in which most of the teachers of the city are trained and which only graduates of the Girls' High School are permitted to enter; the William Penn High School for girls (opened 1909) with academic, commercial, applied arts,
PHILADELPHIA

household science and library economy departments; a School of
industrial arts; two manual training schools; about one hundred
nights schools; numerous Sunday schools for habitual truants or
inconstant and disorderly children; and a number of
summer schools and playgrounds for the summer season.
In 1909 a high school was established as a part of the public
school system. The city has also many private high schools and
academies.

Besides the university of Pennsylvania and the Central
High School for boys the collegiate institutions are La Salle College
(1849), St. Alphonsus College (1865), and Temple University
(founded in 1882 as Temple College by the Pennsylvania
Abolition Society; chartered in 1888 as Temple College after four years
of teaching; in 1891 received the power to confer degrees); which is
designed to prepare students for literary and medical study.
The City College, founded by Russell Hermann Conwell (b. 1842), a lawyer
and journalist, who entered the Baptist ministry in 1879, was pastor of the
Grace Baptist Church of Philadelphia in 1881–1891, became pastor of
First Baptist Church in 1891 and the second president of the college,
which was first established in 1886. He was the first president of the Temple College, which was begun
in connection with the work of his church. Temple University offers
instruction both day and evening, has classes from the
kindergarten to the higher faculty, and contains a school of
engineering, domestic art and domestic science, physical training,
pedagogy and music; it has a theological school (1893, a law school
(1894), a medical school (1901) and a school of pharmacy(1902); and in 1907 the Philadelphia Dental College, and several
dental schools in the country, joined the university. In 1893
a trust fund left by Hyman Gratz was used to found the Gratz
College for the education of teachers in Jewish schools and for the
study of public health, literature, art, music and religion; the college is under the control of the Kaal Kishon Aliko
Israel of Philadelphia. Bryn Mawr College (1889), one of the leading
institutions of the Philadelphia region. A platform of the
Philadelphia Free Library, 1895; in 1904, with occasional "booklets" of
noteworthy books, it is still published as the North American Review, established in 1790 by Benjamin Franklin Bache (1769–1798),
a grandson of Franklin, was a notorious anti-Federalist organ in its
histories, and has often been called the "American Liberty
of the public press. The Public Ledger, founded in 1836, and in 1864 purchased by George
William Childs. Other prominent daily papers now published are the
Inquirer (Republican; 1829), the Press (Republican; 1857),
the Record (Independent Democrat; 1876), the Democratic (1838),
the Evening Bulletin (Republican; established in 1815 as the
American Sentinel), the Evening News (1827), the Evening Telegraph
(Independent Republican; 1864), and the Tageblatt (Labour; German;
1836–1856). The Annals of Philadelphia were published in Philadelphia; among them were the American Magazine
(1757–1758 and 1769), Thomas Paine's Pennsylvania Magazine
(1757–1776), the Columbian Magazine (1765–1790; called the
American Magazine in 1790), which was edited by Matthew Carey and
A. J. Dallas, the excellent American Museum (1787–1792 and
1798), with which Carey was connected, the Port Folio (1801–1827;
edited until 1812 by Joseph Dennie) and the Analectic (1802–1812)
which succeeded Select Reviews and Spiri of the Foreign Magazines
(1800), of which Washington Irving was editor in 1813–1814, and
to which Paulding and Verplanck contributed, and the American
Weekly Magazine (1804–1859). Among others were: Gentleman's
Book (1803–1877), for which Poe, Holmes, Wilkie, and others wrote;
and Graham's Magazine (1820–1859), which, with the contributors just named and Cooper, John G.
Wilkinson and many others, aimed at a semi-monthly, best known for its fiction. The Saturday Evening Post,
which has the largest circulation of the weekly publications, and the
Ladies' Home Journal (1883), the semi-monthly with the largest
circulation among the women's journals, is the leading commercial periodical. The Farm Journal (1877)
is a well-known agricultural monthly.

Trusts, Charities, &c.—Girard College and thirty-eight other
charities are maintained out of the proceeds of as many trusts,
which are invested in a fund to be distributed among the
members, appointed by the courts of common pleas, and the mayor,
president of the select council, and president of the common
council as ex-officio members. In 1907 the invested capital of the
trusts amounted to $24,477,770 and the income therefrom was
$1,988,054. The total capital of all the minor trusts in the same
year was $1,583,026 and the income from this was $56,730. Among
the minor trust funds are: Wills Hospital (established in 1825);
the Thomas D. Grover Fund (1849) for providing the poor with food and
food; Mary Shields Almshouse Fund (1886); and the John Scott Medal Fund (1816) for bestowing medals upon young inventors.

Franklin Institute, Philadelphia is largely undeveloped for the Pennsylvania
hospital. the first hospital in the United States, which was projected
in 1751 and is one of the foremost of nearly one hundred such institutions
in the city. The Philadelphia General Hospital
and hospitals for the indigent and the insane are maintained by the
municipality, but most of the other institutions for the sick are
maintained by medical schools and religious sects. Municipal
moneys are also applied to the support of mental hospitals, health and charities. Philadelphia is the seat of the state peniten-
tiary for the eastern district, in which, in 1829, was inaugurated the "individual system," i.e. the separate imprisonment and dis-
crediting treatment of criminals with a view to effecting their
reform.

Transportation and Commerce.—Nearly every street in the
business centre and about one-third of the streets throughout the
built-up portion of the city have a single track of electric railway (overhead trolley), and most of the wider ones, except Broad Street, which has none, have a double track. A subway line has been opened for a short distance under Market Street, and another subway line, as well as various other subways, lines, and branches. These lines, together with the Baltimore & Ohio railroad, afford transportation facilities north to New York, south to Baltimore, Warrington, and the like, west to the luminescent coalfields of Pennsylvania, the grain fields of the Middle West, and to the cities of Cleveland, Cincinnati and Chicago. The Philadelphia & Reading railway connects the city with the anthracite coal region, and the Philadelphia & Reading & Delaware river & Ohio rail line extends to Atlantic City. The Schuylkill is navigable for small craft to the "Fall line," about 72 m. above its mouth and for vessels drawing 26 ft. to the oil refineries at Point Breeze, 3 m. from the mouth. The manufacture of oil and numerous other products was conducted along the channel depth varies from 14 to 22 ft. The Delaware river is navigable to Trenton, New Jersey, about 30 m. above the upper end of the port of Philadelphia, and although in its natural condition this river was only 17 ft. deep at low water in its shallower part, the depth has been increased by 26 ft. (except in three shoal stretches), and a project of the Federal government was made for increasing it to 30 ft. and the width to 600 ft. In 1905 the city of Philadelphia and the state of Pennsylvania appropriated $750,000 for the improvement of the river between the city and the southern boundary of the state.1 Streets and alleys between the port and the several European ports, ports in the West Indies, and ports of the United States, there are minor harbour facilities on the Schuylkill. The natural facilities, together with the improvements that have been made, were long offset by an inefficient port administration under an antiquated law of 1867 which permitted the wharves to pass largely under private control; but in 1907 the old board of port wardens was abolished and in its place was created a municipal department of wharves, docks and levees.

Until the opening of the Erie Canal, in 1825, Philadelphia was the emporium of the United States; it was then displaced by New York. Some years later Philadelphia lost its lucrative China trade, and when the commercial depression of 1873, 1874, and 1875, when the value of its imports amounted to only $52,811,045, the value of its exports to only $38,662,434, and the city was out-ranked in foreign trade by New York, Boston, San Francisco and New Orleans. By 1900, however, the value of its imports had risen to $49,161,236 and the value of its exports to $81,327,704; in 1909 the value of the imports was $78,903,464, an amount less than one-eleventh that of New York, but exceeded only by New York, Boston, San Francisco, Chicago, and Philadelphia. The imports were valued at $517,898,000, an amount less than one-eighth that of New York, but exceeded only by New York, Galveston and New Orleans. The principal imports are sugar, drugs and chemicals, goatkins, wool, tobacco, etc., as well as iron goods, bread, flour, cereals, sugar, wines, and liquors; the principal exports are iron (manufactured), steel, petroleum, wheat, flour, lard, cattle and meat products. The proximity of the city to New York, whence many of its products are shipped, makes the statistics of its direct imports and exports no true index of its commercial importance.

Manufactures.—Philadelphia has always been one of the foremost manufacturing centres in the United States, and in 1900 it was outranked only by New York and Chicago.2 The total value of its factory product was $519,981,812 in 1900, and $561,388,078 in 1905. Measured by the value of the products, Philadelphia ranked first among the cities in the country in 1875 ($73,182,504; 13.4% of the total of the country) and in the manufacture of carpets and rugs ($25,232,510; 41% of the total of the country), leather ($25,903,239; 9.5% of the total of the country), hosiery and knit goods ($15,779,872; 11.5% of the total of the country), woolen goods ($12,239,881; 8.6% of the total of the country), and felt hats ($5,847,771; 16% of the total of the country); second in the manufacture of worsted goods ($26,694,533; 16% of the total of the country); in the names of those paying poll taxes as well as those paying taxes (on real or personal property); in 1909 there were 80 members of the common council. The several administrative departments

1 The city had previously expended $1,555,000 on the improvement of the Delaware and Schuylkill rivers.

2 A document purporting to be a charter, bearing the date of the 20th of May 1691, and signed by Thomas Lloyd, deputy-governor, was discovered in 1887, but the great seal is missing and there is no other evidence that the charters were ever issued.

3 a meeting of the Council held at Philadelphia on the third day of Sixth Month 1691 mention Humphry Morrey the present Mayor of the city of Philadelphia 4; and this would seem to show that there was a charter of incorporation of the City of Philadelphia: Its Founding and Seals: Report of the Committee... to determine the Year of the Physical and Legal Founding of the City of Philadelphia 1991. The city council was created by an ordinance of 1791 adopted by the Council, and was granted the same authority and powers as the city council of the city of Philadelphia.

4 In 1905 the state legislature took the appointment of these officers from the mayor and vested it in the councils, but this legislation was repealed in 1906.

points, boots and shoes, electrical apparatus, and cordage and twine, and among notable individual establishments are the Baldwin Locomotive Works, the Cramp Ship-Yards and the Diston or Keystone Saw Works. There are petroleum refineries at Point Breeze, the manufacturing plants of the Schuylkill; petroleum is piped to them from the north-west part of the state.

Water Supply.—The first municipal waterworks, installed in 1796-1801, pumped water by steam power from the Schuylkill Hill and its dam at the Spring Garden was supported by a fund; this was one of the earliest applications of steam to municipal water pumping. In 1812-1815 new steam works were installed on Quarry Hill, or Fairmount; in 1819-1822 pumping works operated by water power was started for the supply of steam; and it was in great part for the preservation of the purity of the water supply that Fairmount Park was made. The park, however, did not compass the fair treatment of water, and additional works were installed, mostly on the Schuylkill, whence water was pumped by steam to reservoirs from which distribution was made by gravity; and to meet difficulties in filling demand, steam pumps and accessories were installed in 1901-1908. These take the water mainly from the Delaware river.

Government and Finances.—Inasmuch as it has been proved that in 1863 there was in use in Philadelphia a seal bearing the inscription "Philadelphia 33, William. Penn. Proprietor. and Governor" and in all respects different from the provincial seal or the county seal, it seems that there was then a distinct government for the city. In July 1684 the provincial council, passed by William Penn, appointed a committee to draft a borough charter, but there is no record of the work of this committee, and it is uncertain what the government of Philadelphia was, except for the council of fourteen who issued a charter creating a close corporation modelled after the English borough and under this the city was governed until the War of Independence. Upon the annulment of the Penn charter by the Declaration of Independence, government by commissions was established, but in 1789 a new charter was granted and, although the government has since undergone many and great changes, it is by virtue of this charter that the city remains a corporation to-day. The Consolidation Act of 1854 extended the boundaries to the county lines without destroying the county government, changed the corporate name from "Mayor, Aldermen, and Citizens of Philadelphia" to "the City of Philadelphia," created the offices of controller and receiver of taxes, and considerably modified the powers and duties of the corporation and its officers. The Bullitt Act, passed in 1885 to go into effect in 1887, and since 1885 amended and supplemented, is a new charter except in name; particularly notable is its transfer of the balance of power from the councils and various self-perpetuating commissions to the mayor.

The mayor is elected for a term of four years and is not eligible to the office for the next succeeding term. With the advice and consent of the select council he appoints the directors of the departments of public safety, public works, health and charities, supplies and (since 1907) wharves, docks and ferries, and the three members of the civil service commission. He may appoint three persons to examine any department and for reasons given in writing may remove any officer whom he has appointed. His veto power extends to items in appropriation bills, but any item or ordinance may be passed over his veto within five days of such veto by an affirmative majority in both houses. The select council consists of one member from each of the forty wards, and in the common council each ward has one member for every four thousand names on the last completed assessment list (exclusive of those paying poll taxes as well as those paying taxes (on real or personal property); in 1909 there were 80 members of the common council. The several administrative departments
PHILADELPHIA

are: public safety, public works, receiver of taxes, city treasurer, city controller, law, education, charities and corrections, supply, public and ferries, street, police and fire (as a separate standing fund commission and sinking fund commission (composed of the members of the common council and a commissioner elected by a majority vote of the city council). Members of the select council are elected for three years, one third每年 each year; and the receiver of taxes, the city treasurer, the city controller, and the city solicitor, who is the head of the department of law, for a term of three years. The police force is divided between two departments: safety and patrol, the superintendent of each being a superintendent appointed by the director of the department with the approval of the select council. The department of education is administered by a central board appointed (at large) by the judges of the courts of common pleas.

The assessed value of taxable property in the city increased from $133,369,048 in 1856 to $356,657,534 in 1880, to $580,935,265 in 1890, to $475,811,719 in 1907, and to $629,773,199 in 1917. The city's debt was increased from $5,170,680 in 1856 to $14,640,479 in 1880, to $30,628,246 in 1900, and to $48,012,630 in 1909. The principal items of expenditure in 1909 were: for public schools $8,242,118; for the bureau of water, $2,827,200; for streets and highways, $4,210,260; for police, $3,810,535; and for protection against fire, $1,873,720. The receipts for the same year were $44,372,927, of which $18,851,442 were from the property tax (municipal and state), and $25,521,485 were from the water tax. The city's indebtedness increased rapidly for a period of twenty-five years following consolidation. At the beginning of 1856 the funded debt was $16,000; by the end of 1880 it had grown to $4,401,953, and by the beginning of 1885 to $70,972,097. By the year 1896 the constitution adopted in 1873 no municipality is permitted to create a debt exceeding 7% of the assessed value of its taxable property. In 1909 the state's new fiscal law passed (the so-called "living beyond its income, and as a consequence of these restrictions the funded debt, less loans held by the sinking fund, was reduced by the beginning of 1895 to $33,139,605. The great expense of insulating the new filter plant, doubling the part of the city, and making other improvements has, however, caused it to grow again; at the beginning of 1910 the total funded debt was $95,485,820 and the net funded debt was $84,901,620.

History.—The patent granted to William Penn for the territory embraced within the present Commonwealth of Pennsylvania was signed and sealed on 10th of July (1682) and in April of 1701 and Penn agreed "that a quantity of land or ground so laid out for a large town or city in the most convenient place upon the river for health and navigation, and that every purchaser of 500 acres in the country shall be allowed a lot of 10 acres in the town or city, if the place will allow it." In September 1701, William Penn appointed William Crispin, Nathaniel Allen and John Bezan a committee to proceed to the new province and lay out the city, directing them to select a site on the Delaware where "it is most navigable, high, dry and healthy; that is where most ships can best ride, of deepest draught of water, if possible to load or unload at the bank or key side without boats or pinnaces." The site selected is the present site of Philadelphia. In 1702, the lots were laid out by survey, and in 1703 a grant of 600 acres was made to the town for making a city extending from the Delaware river on the east to the Schuylkill river on the west, a distance of about 2 m., and from Vine Street on the north to Cedar (now South) Street on the south, a distance of about 1 m. Penn landed at New Castle on the Delaware on the 27th of October 1682 and two days later came on as far as Upland, now Chester, 13 m. south of Philadelphia, but when he came to his newly founded city is not known. He is known, however, to have presided at a meeting of the provincial council held here on the 10th of March 1683, and from that time Philadelphia was the capital of Pennsylvania until 1799, when Lancaster became the capital. During the early part of this period it was also the most important city commercially, politically and socially in the colonies. Quaker influence remained strong in the city, especially up to the beginning of the 19th century; and it was predominant in Philadelphia long after it had given way before the Scotch-Irish in the rest of Pennsylvania. But even in Philadelphia the academy (later the university of Pennsylvania) soon came under the control of the Protestant Episcopal Church. The first Continental Congress met in Carpenter's Hall on the 4th of September 1774; the second in the old state house (Independence Hall) on the 10th of May 1775; and throughout the War of Independence, except from the 26th of September 1777 to the 18th of June 1778, when it was in possession of the British. Philadelphia was the virtual capital of the colonies; it was a brilliant social city, especially during the British possession. The national convention which framed the present constitution of the United States sat in Philadelphia in 1787, and from 1790 to 1800 the city was the national capital. Here Benjamin Franklin and David Rittenhouse made their great contributions to science, and here Washington delivered his farewell address to the people of the United States. Here, in July 1790, the clerical and lay delegates from the Protestant Episcopal Churches in the United States met and formally organized the Protestant Episcopal Church in the United States. Here the first bank in the colonies—the Bank of North America—was opened in 1781, and here the first mint for the coinage of the money of the United States was established in 1792. The city was visited with an epidemic of yellow fever in 1793 and again in 1798; and in 1832 nearly 1,000 inhabitants died of Asiatic cholera.

The original boundaries remained unchanged for 172 years, but the adjoining territory as it became populated was erected into separate districts in the following order: Southwark (1762), Northern Liberties (1771), Moyamensing (1812), Spring Garden (1813), Kensington (1820), Penn (1844), Richmond (1847), West Philadelphia (1851) and Belmont (1853). In 1834 all these districts, together with the boroughs of Germantown, Frankford, Manayunk, White Hall, Bridesburg and Aramingo, and the townships of Passyunk, Blockley, Kingsessing, Roxborough, Germantown, Bristol, Oxford, Lower Dublin, Moreland, Byberry, Delaware and Penn was abolished and the boundaries of Philadelphia were extended to the county lines by a single act of the state legislature. The consolidation was in part the outcome of a demand for efficiency in preserving order. There had been occasional dissatisfaction. On the 17th of May 1838 an anti-abolition mob had burned Pennsylvania Hall at Philadelphia, which had been dedicated three days before to the discussion of abolition, temperance and equality; in May 1844 anti-Catholic rioters had burned St Michael's and St Augustine's churches, and minor riots had occurred in 1835, 1842 and 1843. Philadelphia was from the first strongly anti-slavery in sentiment, and it was here in December 1833 that the American Anti-Slavery Society was organized, and in 1836, on the anniversary of the battle of Bunker Hill, that the first national convention of the Republican party met. During the Civil War the arsenal and the Southwark navy yard were busy manufacturing material for Federal and the Confederate States, the city was crowded with wounded soldiers, and here in 1864 was held the great sanitary fair for the benefit of the United States sanitary commission, an organization for the relief and care of wounded and sick soldiers. In 1876, the centennial year of American independence, a great exhibition of the industries of all nations was held in Fairmount Park from the 10th of May to the 10th of November, and about fifty buildings were erected for the purpose. In October 1882 the city celebrated the bi-centennial of the landing of William Penn, and in October 1906 the 225th anniversary of its foundation.

Lord Howe, who had been in command of the British, embarked for England on the 24th of May, and on the 18th of this month was held for his farewell entertainment the famous Mischievous, a feast of gaiety with a tournament somewhat like those common in the age of chivalry, which was in large part planned by Captain John Anster.
PHILADELPHIANS—PHILARET

PHILADELPHIANS, a sect of religious mystics, founded in London in the latter part of the 17th century. In 1652 Dr John Pordage (1607-1681), rector of Bradford, Berkshire, gathered together a few followers of Jakob Boehme, the chief of whom was Jane Lead or Leade (née Ward; 1622-1704). Pordage was ejected from his living by the Tiers in 1655, but was restored in 1660. Mrs Leade had been from girlhood of a mystical temperament, and experienced phantasms which she recorded in a diary entitled A Fountain of Gardens, beginning in 1670, in which year the Philadelphian society was definitely organized. She drew up for it "The Laws of Paradise," which show that the enterprise was designed "to advance the Kingdom of God by the means of the following truths: undefiling the duty of universal brotherhood, peace and love." Its members had a strong faith in what they called the "Divine Secrets," the wonders of God and nature, the profound spiritual experiences of regeneration and soul-resurrection, and the second Advent. In 1693 some of Mrs Leade's writings were translated into Dutch, and by this means and her acquaintance with Francis Lee (1661-1719), an Oxford scholar who studied medicine at Leiden and became her son-in-law, a connexion was opened up with Germany and Holland. In 1703 the Philadelphians gave up their connexion, but they made no further progress and soon declined. The Holland branch withdrew, and the English government forbade the society to meet. For many years, however, a considerable number of people regarded Mrs Leade's visions, which were published in a long series of writings, as proofs of her divine calling. In her later years she had a severe struggle with poverty, which was relieved by a pension granted by Baron Kniphausen.

PHILAE, an islet in the Nile above the First Cataract, of great beauty and interest, but since the completion of the Aswan dam in 1902 submerged except for a few months yearly during High Nile (July to October), when the water is allowed to run freely through the sluices of the Asuan dam. Philae is the nearest island to the point where the ancient desert road from Aswan meets the river south of the cataract. It marks also the end of the cataract region. Below it the channel is broad and starkly with granite islands to the west. The name in Egyptian was Plak, "the angle (?) island;" the Arabs call it Anas el Wagad, after the hero of a romantic tale in the Arabian Nights. Ancient graffiti abound in all this district, and on Bigha, a larger island adjoining Philae, there was a temple as early as the reign of Tethmosis III. The name of Amasis II. (570-535 B.C.) is said to have been found at Philae, and it is possible that there were still older buildings which have been swallowed up in later constructions. About 350 B.C. Nekhtnef, the last of the native kings of Egypt, built a temple to Isis, most of which was destroyed by floods. Ptolemy Philopator reconstructed some of this work and began a large temple which Ptolemy Euergetes I completed, but the decoration, carried on under later Ptolemies and Caesars, was never finished. The temple of Isis was the chief sanctuary of the Dodecachoerus, the portion of Lower Nubia generally held by the Ptolemies and Romans. The little island won great favour as a religious resort, not only for the Egyptians and the Ethiopians and others who frequented the border district and the market of Aswan, but also for Greek and Roman visitors. One temple or chapel after another sprang up upon it dedicated to various gods, including the Nubian Mandulis. Ergamenes (Arkamane), King of Ethiopia, shared with the Ptolemies in the building. Besides the temple of Isis with its birth-temple in the first court, there were smaller temples or shrines of Amonophis, Mandulis, Imubes, Hathor, Harendotes (a form of Horus) and Augustus (in the Roman style), besides unnamed ones. There were also monumental gateways, and the island was protected by a stone quay all round with the necessary staircases, &c., and a Nilometer. The most beautiful of all the buildings is an unfinished kiosk inscribed by Trajan, well known under the name of "Pharaoh's Bed." Graffiti of pilgrims to the shrine of Isis are dated as late as the end of the 5th century A.D. The decree of Theodosius (A.D. 378) which suppressed pagan worship in the empire was of little effect in the extreme south. In A.D. 455 Maximinus, the governor of the Thebaid, burned the temple of the goddess, after inflicting a severe defeat on the Nobatae and Blemmyes who were settled in Lower Nubia, and thence raided Upper Egypt, made peace on terms which included permission for these heathen tribes to visit the temple and even to borrow the image of Isis on certain occasions. It was not till the reign of Justinian, A.D. 527-565, that the temple of Philae was finally closed, and the idols taken to Constantinople. Remains of Christian churches were disclosed by the thorough exploration carried out in 1865-1866 in view of the Barrage scheme, under the direction of Captain Lyons. The accumulations of rubbish on the island were cleared away and the walls and foundations of the temple were removed when it was strengthened before the dam was completed. The annual flooding now appears to be actually beneficial to the stonework, by removing the disintegrating salts and incorustations. The tops of most of the buildings and the whole nucleus of the temple of Isis to the floor remained all the year round above the water level until the dam was raised another 26 ft.—a work begun in 1907—when the temples were entirely submerged except during July-October. But the beauty of the island and its ruins and palm trees, the joy of travellers and artists, is almost gone.

See H. G. Lyons, A Report on the Island and Temples of Philae ( Cairo, 1866), with numerous plans and photographs; a second report, A Report on the Temples of Philae (1908), deals with the condition of the ruins as affected by the immersions occasioned by the filling of the Assuan dam; Baedeker's Egypt; and on the effects of the submersion, &c., reports in Annales du service des antiquités, vol. iv. (P. L. G.)

PHILARET [THEODORE NIKITICH ROMANOV] (1553-1633), patriarch of Moscow, was the second son of the boyar Nikita Romanovich. During the reign of his first cousin Theodore I. (1584-1598), Theodore Romanov distinguished himself both as a soldier and a diplomatist, fighting against the Swedes in 1590, and conducting negotiations with the ambassadors of the emperor Rudolph II. in 1593-1594. On the death of the Tsar, he was the ablest of the regents, and after inflicting a severe defeat on the nobles and Blemmyes who were settled in Lower Nubia, and thence raided Upper Egypt, made peace on terms which included permission for these heathen tribes to visit the temple and even to borrow the image of Isis on certain occasions. It was not till the reign of Justinian, A.D. 527-565, that the temple of Philae was finally closed, and the idols taken to Constantinople. Remains of Christian churches were discovered by the thorough exploration carried out in 1865-1866 in view of the Barrage scheme, under the direction of Captain Lyons. The accumulations of rubbish on the island were cleared away and the walls and foundations of the temple were removed when it was strengthened before the dam was completed. The annual flooding now appears to be actually beneficial to the stonework, by removing the disintegrating salts and incorustations. The tops of most of the buildings and the whole nucleus of the temple of Isis to the floor remained all the year round above the water level until the dam was raised another 26 ft.—a work begun in 1907—when the temples were entirely submerged except during July-October. But the beauty of the island and its ruins and palm trees, the joy of travellers and artists, is almost gone.

See H. G. Lyons, A Report on the Island and Temples of Philae ( Cairo, 1866), with numerous plans and photographs; a second report, A Report on the Temples of Philae (1908), deals with the condition of the ruins as affected by the immersions occasioned by the filling of the Assuan dam; Baedeker's Egypt; and on the effects of the submersion, &c., reports in Annales du service des antiquités, vol. iv. (P. L. G.)
domestic measure was the chaining of the peasantry to the soil, a measure directed against the ever increasing migration of the doors and farmers to the towns, where they became free-booters instead of tax-payers. The taxation of the tsar's 

dynasts lyeus; or military tenants, was a first step towards the proportional taxation of the hitherto privileged classes. Philaret's zeal for the purity of orthodoxy sometimes led him into excesses; but he encouraged the publication of theological works, formed the nucleus of the subsequently famous Patriarchal Library, and commanded that every archbishop should establish a seminary for the clergy, himself setting the example. Another great service rendered by Philaret to his country was the reorganization of the Muscovite army with the help of foreign officers. His death in October, 1663, put an end to all but a shadow of the Polish War (1622–35), withdrawing the strongest prop from an executive feeble enough even when supported by all the weight of his authority.

PHILATELIC (Gr. φιλος, loving, and ἄπειδη, free of tax), the study and collection of postage-stamps and other marks of prepayment issued by post-offices. The fancy for collecting postage-stamps began a short time after the issue of the first British penny and two-penny stamps in 1840 (see Post and Postal Services). Dr Gray, an official of the British Museum, began collecting them soon after their appearance, and an advertisement in an issue of The Times of 1841 asks for tickets of cancelled stamps for a young lady. In 1842 the new hobby was ridiculed in Punch. It was not until about 1860, however, that stamp collecting began to be systematically carried on with full regard to such minutiae as the different kinds of paper, water-marks, perforation, shade of colour and distinctive outline. About 1862 a teacher in Paris directed that foreign stamps should be collected and pasted upon the pages of his pupils' atlases and geographies according to countries, and this may have been the first form of the systematic classification of stamps in a collection. Of existing collections the oldest were begun between 1853 and 1866, by which year French collectors had assumed especial prominence. Professional dealers now made their appearance, and in 1861 philatelic literature, now of vast extent, was inaugurated by the publication in Strasbourg of a catalogue of stamps issued up to that time. The Paris collectors were the first to classify stamps, measure them by the gauge, note the water-marks and separate the distinct issues of each country. Collecting with due regard to the relationship of different issues is called plating. The first English catalogue was issued in 1863, followed in December of the same year by The Stamp Collector's Review and Monthly Advertiser, published in Liverpool, the first philatelic periodical, the second, The Stamp Collector's Magazine, appearing in 1863. In 1863 also appeared Le Timbre-Poste, a Brussels journal. Up to 1910 over 800 philatelic periodicals had appeared.

Although small bodies of enthusiasts had banded together in England, France and the United States for the study and collection of postage-stamps as early as 1865, it was not until 1869 that the first great club, the Philatelic Society of London, still the most important in the world, was founded. Other societies in Great Britain are the Junior Philatelic of London, and those of Birmingham, Manchester, Edinburgh and Leith. The leading society in America is the American Philatelic Association; in France the Société française de timbres; in Germany the Internationale Philatelisten-Verein. More than 400 such organizations are now in existence, the majority of them in the United States and Germany. At a philatelic congress, held in London in 1910, the formation of a universal union of philatelic societies "to discourage unnecessary or speculative issues" was considered.

Not only the stamps themselves were collected, but "entires," i.e. postcards, envelopes with the stamps still adhering, &c. Marks of prepayment at last became so numerous that, about 1880, specialists began to appear, who restricted their collections to the stamps of some particular country or continent, or to postcards or newspaper-wrappers alone. The most extensive and valuable stamp collection in the world, that of Baron P. von Ferrary of Paris, was begun about 1865. This collection, which cost its owner at least £250,000, contains a cancelled and an uncancelled specimen of each stamp. The next greatest collection is that bequeathed to the British nation in 1891 by T. K. Tapling, M.P., now in the British Museum. Among other important collections may be mentioned those in the German Postal Museum in Berlin, of King George V. of England, W. B. Avery, H. J. Duvene and the earl of Crawford. The largest sum realized for an entire collection was £27,500, which was paid for that of M. P. Castle, consisting of European stamps only. The value of a stamp depends very little upon its rarity, but more upon its popularity. Most stamps have a quoted value, but some possess a conventional value only, such as those of which only one or two specimens are known to exist; for instance, the one-cent stamp of the 1856 issue of British Guiana (one known copy); the Italian 15 centesimi stamp of 1865 converted by an overprint into 20 centesimi (one copy); the Cape of Good Hope triangular, printed by mistake on paper intended for stamps of other colonies (four copies); and the 2 cent stamps of the earliest issue of British Guiana (ten copies). The best known of the very rare stamps are the 2d. and 2½d. Post Office Mauritius, two stamps of which are known for any other stamps, although 23 copies are known to exist out of the 1000 issued. For a fine specimen of these Mauritius stamps £2000 has been offered. Two of them have been sold for £2400. Philatelic exhibitions such as those held in London in 1890 and 1897, and in Manchester in 1909 have proved popular.

' Reprints ' are re impressions, taken from the original plates, of obsolete stamps, and have much less value than specimens of the original issue. Forgeries of the rarer stamps are common but are easily detected. Modern postage-stamp albums are often beautiful specimens of the printer's art, reproductions of every known stamp being given in the original colours.

PHILEMON (c. 367–353 B.C.), Greek poet of the New Comedy, was born at Soli in Cilicia, or at Syracuse. He settled at Athens early in life, and his first play was produced in 330. He was a contemporary and rival of Menander, whom he frequently vanquished in poetical contests. Posteriority reversed the verdict and attributed Philemon's successes to unfair influence. He made a journey to the east, and resided at the court of Ptolemy, king of Egypt, for some time. Plutarch (De Cothibus Ira, 9) relates that on his journey he was driven by a storm to Cyrene, and fell into the hands of his king Magas, whom he had formerly satirized. Magas treated him with contempt, and finally dismissed him with a present of toys. Various accounts of his death are given; a violent outburst of laughter, excess of joy at a comic song, or a successful escape while embroiled in controversy was his last work (Apuleius, Florida, 16; Lucian, Macrobr. 25; Plutarch, An Seni, p. 725). Of the ninety-seven plays which he is said to have composed, the titles of fifty-seven and considerable fragments have been preserved. Some of these may have been the work of his son, the younger Philemon, who is said to have composed fifty-four comedies. The Merchant and The Treasure of Philemon were the originals respectively of the Mercator and Trinummus of Plautus. The fragments preserved by Stobaeus, Athenaeus and other writers contain much wit and good sense. Quintillian (Inst. 1. x. 72)
PHILEMEN, EPISTLE TO—PHILETAS

PHILEMEN and BAUCIS, the hero and heroine of a beautiful story told by Ovid (Metam. viii. 610–715), the scene of which is laid in Phrygia. Zeus, accompanied by Hermes, visited earth in human form; tired and weary, they sought shelter for the night, but all shut their doors against them except an aged couple living in a humble cottage, who afforded them hospitality. Before their departure the gods revealed themselves, and bade their hosts follow them to the top of a mountain, to escape the punishment destined to fall on the rest of the inhabitants. The country was overwhelmed by a flood; the cottage, which alone remained standing, was changed into a magnificent temple. The gods appointed Philemon and Baucis priest and priestess, and granted their prayer that they might die together. After many years they were changed into trees—Philemon into an oak, Baucis into a lime. The story, which emphasizes the sacred duty of hospitality, is probably of local Phrygian origin, put together from two widely circulated legends of the visits of gods to men, and of the preservation of certain individuals from the flood as the reward of piety. It lingers in the account (Acts xiv.) of the healing of the lame man by Paul at Lystra, the inhabitants of which identified Paul and Barnabas with Zeus and Hermes. "come down in the likeness of men."

Similar stories are given in J. Grimmel, Deutsche Mythologie (Eng. trans., 1853, ii. 580–585, 590–596).  

PHILEMEN MANUEL (c. 1725–1749), of Ephesus, Byzantine poet. At an early age he removed to Constantinople, where he was the pupil of Georgius Pachymeres, in whose honour he composed a memorial poem. Philes appears to have travelled extensively, and his writings contain much information concerning the imperial court and distinguished Byzantines. Having offended one of the emperors by indiscreet remarks published in a chronography, he was thrown into prison and only released after an abject apology. Philes is the counterpart of Theodorus Prodromus in the history of the Comment; his character, as shown in his poems, is that of a beggar poet, always pleading poverty, and ready to descend to the grossest flattery to obtain the favourable notice of the great. With one unimportant exception, his productions are in verse, the greater part in dactylic and iambic trimeters, the remainder in the fifteen-syllable "political" measure.

Philes was the author of poems on a great variety of subjects: on the characteristics of animals, chiefly based upon Aelian and Oppian, a didactic poem of some 2000 lines, dedicated to Michael Palaeologus; on the elephant; on plants; a necrological poem, probably written on the death of one of the sons of the Pselphes family. All of his work is written in a variety of styles, from the affectation of John Cantacuzene, in the form of a dialogue; a conversation between a man and his soul; on ecclesiastical subjects, such as church festivals, Christian beliefs, the saints and fathers of the church; on men, especially his own times, his friends, his pieces for their bearing on Byzantine iconography, since the writer had before him the works he describes, and also the most successful from a literary point of view; occasional poems, many of which simply begin "in the year..."

Editions: the natural history poems in F. Lehms and F. Dabner, Poetae boculici et didacticci (Didot series, 1846); Manuelis Philae Carmine inedita, ed. T. Martini (1800); Manuelis Philae Carmina ed. J. C. Raths (1856). In addition, also C. Krummacher, Geschichte der Byzantinischen Literatur (1897).

PHILETAS of Cos, Alexandrian poet and critic, flourished in the second half of the 4th century B.C. He was tutor to the son of Ptolemus I of Egypt, and also taught Theocritus and the grammarian Zenodotus. His thinness made him an object of ridicule; according to the comic poets, he carried lead in his shoes to keep himself from being blown away. Over-study of Megarian dialectic subtleties is said to have shortened his life. His elegies, chiefly of an amatory nature and singing the praises of his mistress Battis (or Bitis), were much admired by the Romans. He is frequently mentioned by Ovid and Propertius, the latter of whom imitated him and preferred him to his rival Callimachus, whose superior mythological lore was more to the taste of the Alexandrian critics. Philetas was also the author of a vocabulary called Araeza, explaining the meanings of rare...
PHILIDOR—PHILIP (KINGS OF MACEDONIA)

and obscure words, including words peculiar to certain dialects; and of notes on Homer, severely criticized by Aristarchus.

Fragments edited by N. Bach (1828), and T. Bergk, Poetae lyrici graeci; see also E. W. Maass, De tribus Philaei carminibus (1895).

PHILIDOR, FRANÇOIS ANDRÉ DANICAN (1726-1795),
French composer and chess-player, was born at Dreux, on the 7th of September 1726, of a musical family. The family name was Danican, but that of Philidor, added in the middle of the 17th century, eventually supplanted the older name. François André received a musical education as a member of the corps of pages attached to the orchestra of the king; and subsequently he earned his living by giving lessons and copying music. Much of his time was, however, devoted to chess, at which he soon became an expert. He spent many years in travelling on the Continent and in England, meeting and defeating the most noted players of the time, and is regarded as the strongest player and greatest theoretician of the 18th century. Returning to France in 1754, he resolved to devote himself seriously to musical composition, and after producing several works of minor importance brought out at Paris, in the year 1756, his successful light opera, Blaise le Sorcier, which was followed by a number of others, notably Le Soldat magicien (1760), Le Jardinier et son seigneur (1761), Le Sorcier (1762), and Tom Jones (1764).

He died in London on the 31st of August 1795.

PHILIP (Gr. Φίλιππος, fond of horses, from φίλος, to love, and ῥός, horse; Lat. Philippus, whence e.g. M. H. Ger. Philippes, Dutch Filip, and, with dropping of the final s, It. Filippo, Fr. Philippe, Gr. Philipp, Sp. Felipe), a masculine proper name, popularized among the Christian nations as having been that of one of the apostles of Christ. Notices of distinguished men who have borne this name are arranged below in the following order: (1) Biblical; (2) Kings of Macedonia, France, Germany and Spain; (3) Other rulers.

PHILIP, one of the twelve apostles, mentioned fifth in all the lists (Matt. x. 3; Mark iii. 18; Luke vi. 14; Acts i. 13). He is a mere name in the Synoptists, but a figure of some prominence in the Fourth Gospel. There he is said to have been "of Bethsaida, the city of Andrew and Peter," and to have received his call to follow Jesus at Bethany, having previously been, it would seem, a disciple of the Baptist (John i. 43, 44; cf. 28). Philip was at that time the means of bringing Nathanael to Jesus (John i. 45), and at a later date he, along with Andrew, carried the request of the inquiring Greeks to the Master (John xii. 22). Philip is also mentioned by name in connexion with the feeding of the five thousand (John vi. 4, 7), and Philip is also one of the few interlocutors in John xiv. Slight though these references are, all agree in presenting Philip as of an inquiring and calculating character, slow to take the initiative, but, when convinced of the path of duty, thoroughly loyal in following it.

After the resurrection he was present at the election of Matthias as successor to Judas, but he does not again appear in the New Testament history; it is, however, implied that he still continued in Jerusalem after the outbreak of the first persecution.

Little reliance can be placed on the traditional accounts of Philip. They are due to the evident confusion that has arisen between him and the evangelist of the same name, who appears in the book of Acts (see below). According to Polycrates, bishop of Ephesus, in his controversial letter written to Victor of Rome towards the end of the 2nd century (ap. Euseb. H. E., iii. 31, v. 24), the graves of Philip "of the twelve apostles," and of his two aged virgin daughters were in (the Phrygian) Hierapolis; a third daughter, "who had lived in the Holy Ghost," was buried at Ephesus. With this may be compared the testimony of Clement of Alexandria, who incidentally (Strom. iii. 6) speaks of "Philip the Apostle" as having begotten children and as having given daughters in marriage. On the other hand, Proclus, one of the interlocutors in the "Dialogue of the Cyprians," a writing of somewhat later date than the letter of Polycrates, mentions (ap. Euseb. H. E., iii. 31) "four prophetesses, the daughters of Philip at Hierapolis in Asia, whose tomb and that of their father are to be seen there," where mention of the daughters prophesying identifies the person meant with the Philip of Acts (cf. Acts xxi. 8). The reasons for setting aside this latter identification, and for holding that the Philip who lived at Hierapolis was the Apostle are clearly stated by Lightfoot, Colossians (x) note 3, p. 45 seq., and fresh confirmation of his view has recently been afforded by the discovery of an inscription at Hierapolis, showing that the church there was dedicated to the "sacred memory of the holy and glorious apostle and theologian Philip" (Ramsay, Cities and Bishops of Phrygia, vol. i., pt. ii. p. 552).

See also Corssen, "Die Töchter des Philippus" in the Zeitschrift für die neutestamentliche Wissenschaft (1901), p. 289 sqq. The other view, that the Philip of Hierapolis is the Philip of Acts, is taken by Zahn, Forschungen zur Geschichte des neutestamentlichen Kanons (1900), vi. 158 sqq.

A later stage of the tradition regarding Philip appears in various late apocryphal writings which have been edited by Tischendorf in his Acta apostolorum apocrypha, and in his Apocalypses apocryphae. According to the Acts Philippi, a work belonging at the earliest to the close of the 4th century (see Zahn, op. cit. p. 18 sqq.), Philip, with Bartholomew and his own sister Mariamne, exercised a widespread missionary activity, preaching not only throughout Asia Minor, but also in Hellas the city of the Athenians, in Scythia, and in Gaul, &c. According to one account he died a natural death; according to another he was hanged or crucified, head downwards. An apocryphal gospel, which describes the progress of the soul through the next world, bears his name (Hennecke, Neutestamentliche Apokryphen, 1904, p. 40 seq.).

Since the 6th century Philip has been commemorated in the West, along with St James the Less, on the 1st of May, their relics being deposited in the same church in Rome; in the Eastern Church Philip's day is the 14th of November, and that of James the Less the 23rd of October.

PHILIP, "the evangelist," is first mentioned in the Acts (vi. 5) as one of "the seven," who were chosen to attend to certain temporal affairs of the church in Jerusalem in consequence of the murmurings of the Hellenists against the Hebrews. After the martyrdom of Stephen he went to "the city of Samaria," where he preached with much success, Simon Magus being one of his converts. He afterwards instructed and baptized the Ethiopian eunuch on the road between Jerusalem and Gaza; next he was "caught away" by the Spirit and found at Azotus (Ashdod), whence "passing through he preached in all the cities of that part of the country" (Acts viii.). Here some years afterwards, according to Acts xxi. 8, 9, where he is described as "the evangelist" (a term found again in the New Testament only in Eph. iv. 11; 2 Tim. iv. 5), he entertained Paul and his companion on their way to Jerusalem; at that time "he had four daughters which did prophesy." At a very early period he came to be confounded with the apostle Philip (see above); the confusion was all the more easy because, as an esteemed member of the apostolic company, he may readily have been described as an apostle in the wider sense of that word (see further Salmon, Intro. to the New Testament, 7th ed., p. 313sqq.). A late tradition describes him as settling at Tralleis in Asia Minor, where he became the memory of a church. "Philip the deacon" is commemorated on the 6th of June.

PHILIP I., king of Macedonia, a semi-legendary prince, son of Argeus, was, according to Herodotus (viii. 137-139) and Thucydides (ii. 100), the third of the Macedonian kings. In the texts of Dexippus and Eusebius he ranks sixth, Carolus, Coenus and Thurimis (or Turimis) being there regarded as the predecessors of Perdiccas I., whom Herodotus and Thucydides regard as the first king of Macedonia. Eusebius and Dexippus assign to Philip I. a reign of 38 and 35 years respectively. There is, however, no real evidence for his existence.

(E. R. B.)

PHILIP II. (382-336 n.C.), king of Macedonia, the son of Amyntas and the Lyncestian Eurydice, reigned 359-336. At his birth the Macedonian kingdom, including the turbulent peoples of the hill-country behind, was very imperfectly consolidated. In 370 Amyntas died, and the troubled reign of
Philip (Kings of Macedonia) 377

Philip's eldest brother, Alexander II., was cut short in 368 by his assassination. His murderer, Tteolley of Alorus, ruled as regent for the young Perdikkas, Amyntas's second son. In 367 Philip was delivered as hostage to the Thebans, then the leading power of Greece (by whom does not seem clear). During the three years he spent at Thebes the boy no doubt observed and learnt much. When he returned to Macedonia (364) Perdikkas had succeeded in getting rid of Tteolley; but he fell in 360–359 before an onset of the hill tribes instigated by the queen-mother Eurydice, leaving only an infant son. Various pretenders sprang up and the kingdom fell into confusion. Philip seized the throne and drove back his rivals. He now began the great task of his life—the creation of the Macedonian empire. His successes and the experiment he made with this new organism was brilliantly successful. The hill tribes were broken by a single battle in 358, and Philip established his authority inland as far as Lake Ochrida. In the autumn of the same year he took the Athenian colony, Amphipolis, which commanded the gold-mines of Mt Pangaen. Their possession was all-important for Philip, and he set there the new city, called after him, Philippi. Athens was temporarily pacified by assurances that Amphipolis would be handed over to her later on. The work of fashioning the Macedonian army occupied Philip for the next few years, whilst his diplomacy was busy securing partisans within the states of Greece. He avoided as yet a forward policy and having taken Pydna and Potidaea soon after Amphipolis, he made them over to the Olynthian confederation (see OLYNTHUS). His marriage with the fierce witch-woman, Olympias, daughter of the Epiprince, kings in this period, and in 356 she bore him his greater son, Alexander. In 353 Philip was ready for strong action. He first attacked Adera and Maroeea, on the Thracean sea-board, and then took Methone, which belonged to Athens. An overt breach with Athens was now inevitable. In the same summer he invaded Thessaly, where the Alexeadae of Larissa ranged themselves on his side against the lagus Lykophon,47 tyrant of Phere. Phere called in the help of the Phocian mercenaries, who had profaned Delphi, and Philip met with a check. He had, however, the advantage of now being able to present himself to the Greeks as the champion of Apollo in a holy war, and in 352 the Macedonian army won a complete victory over the Phocaeans and Phocians. This battle made Philip lagus of Thessaly, and he claimed as his own Magnesia, with the important harbour of Pagasae.hostilities with Athens did not yet take place, but Athens was threatened by the Macedonian party which Philip's gold created in Euboea.

From 352 to 346 Philip did not again come south. He was active in completing the subjugation of the Balkan hill-country to the west and north, and in reducing the Greek cities of the coast of Chalcidice. He left there (Marsia), however, Olynthus, he continued to profess friendship till its neighbour cities were in his hands. Then, in 349, he opened war upon it. Athens, to whom Olynthus appealed, sent no adequate forces, in spite of the uprisings of Demosthenes (see his Olynihezai), and in the spring of 347 Olynthus fell. Philip razed it to the ground (see OLYNTHUS). Macedonia and the regions adjoining it having now been securely consolidated, Philip celebrated his "Olympian" games at Dium. In 347 Philip advanced to the conquest of the eastern districts about the Hebrus, and compelled the submission of the Thracian prince Cerseolopes. Meanwhile Athens had made overtures for peace (see the De falsa legatione of Demosthenes), and when Philip, in 346, again moved south, peace was sworn in Thessaly. The time was come for Philip to assert himself in Greece, and the Phocians, who still dominated Delphi and held Thermopylae, could furnish a pretext to the champion of Pan-Hellenism and Apollo. The Phociac mercenaries at Thermopylae were bought off and Philip crossed into central Greece. Here he made Thebes his ally and visited the Phocians with crushing vengeance. The Pythian games of 346 were celebrated at the delivered Delphi under Philip's presidency. Pan-Hellenic enthusiasts already saw Philip as the destined captain-general of a national crusade against Persia (Isocrates, Philippus, about 343). And such a position Philip had determined to secure: the Macedonian agents continued to work throughout the Greek states, and in the Peloponnesus Sparta soon found herself isolated. Euboea, too, submitted to Macedonian influence, and even received some garrisons. But more work had to be done in the Balkan highlands. In 344, or one of the following years, the Macedonian arms were carried across Epirus to the Adriatic. In 342 Philip led a great expedition north "comparable to nothing in antiquity since Darus' famous march to Scythia." In 341 his army was still campaigning in eastern Thrace, when Philip felt compelled to show his presence in Thrasyly. During these years, although Athens had not overtly broken the peace of 346, there had been secret contacts between Macedonia and hostile intrigues between the two powers (cf. the Philippics of Demosthenes). Athens had even sent emissaries to the Persian court to give warning of the proposed national crusade. She now egged on the cities of the Propontis (Byzantium, Perinthus, Selymbria), who felt themselves threatened by Philip's Thracian conquests, to declare against him. The sieges of Perinthus and Byzantium (340, 339) ended in Philip's meeting with a signal check, due in some measure to the help afforded the besieged cities by Athens and her allies. Philip's influence all over Greece was compromised. But before marching south he led another expedition across the Balkans into the country now called Bulgaria, and returned to Pella with much spoil but severely wounded in the thigh. In 338 he began more crossed into central Greece. The pretext was the constumey shown by the Locrian town Amphissa to the rulings of the Amphictyonic Council. Philip's fortification of Elatea filled Athens with alarm. Thebes was induced to join Athens; so were some of the minor Peloponnesian states, and the allies took the field against Philip. This opposition was crushed by the epoch-making battle of Chaeroneia, which left Greece at Philip's feet. In the following year (337) Philip was in the Peloponnesus, and a congress of the Greek states at the Isthmus (from which, however, Sparta held sullen aloof) recognized Philip as captain-general for the war against Persia. Philip returned to Macedonia to complete his preparations; an advanced force was sent into Asia in the spring of 336. But Philip's plans were suddenly blasted by his assassination in the same year during the marriage festival of his daughter at Aegae, the old capital of Macedonia. He left, however, in the Macedonian army a splendid instrument which enabled his son within ten years to change the face of the world.

Philip stands high among the makers of kingdoms. Restless energy, determination, a faculty for animating and organizing a strong people, went with unscrupulous duplicity and a full-blooded vehemence in the pleasures of sense. Yet Philip was not untouched by ideal considerations, as is proved by the respect he paid to the Macedonian national heterarchy, by the forbearance and deference with which he treated Athens, the sacred city of that culture and his mortal foe. A special interest belongs to the Macedonian kingdom as it was shaped by Philip, since it forestalls a system which was not to find the time ripe for it in European history till many centuries later—the national kingdom quickened with the culture developed by the ancient city-states. The national kingdoms founded by the Northern races, after the fall of the Roman Empire, under the influence of the classical tradition, are the beginnings of the modern European system; Philip of Macedon foreshadows Theodoric, Charlemagne and William the Conqueror. But this first national kingdom within the sphere of Greek culture could not ultimately live between the surge of the Northern barbarians and the Roman power.

See the authorities under GREECE: History. A vivid and masterly sketch of Philip's personality and work is given in D. G. Hogarth's Philip and Alexander (1897).

(E. R. B.)

PHILIP III. [ARRHIDAEUS], king of Macedonia, was the feeble-minded son of Philip II. of Macedonia by a Thessalian wife. He was chosen by the Macedonian army at Babylon in 323 to be nominal king conjointly with the Infant Alexander, and was killed in Macedonia by order of Olympias (317). (See Macedonian Empire)
PHILIP IV., king of Macedonia, was the son of Cassander, king of Macedonia: he reigned only one year (297-296).

PHILIP V., king of Macedonia, son of Demetrius II. and Chryseis, was an infant at his father's death in 295-292 B.C. This incident has been mistaken by some for the death of Philip II. of Macedon, as regent till his death in 221-220, when Philip was eighteen years old. Philip now ascended the throne and reigned till 179. His reign was occupied in the vain struggle to maintain the old Macedonian supremacy in the Balkan Peninsula, which became hopeless after the intervention of Rome and the decisive battle of Cynoscephalae (197). See Rome: History, § II. "The Republic" (period B, § b). (E. R. B.)

PHILIP I. (1052-1108), king of France, eldest son of Henry I. of France and Anne, daughter of Jaroslav I. (d. 1054), grand duke of Kiev, came to the throne, when a child of eight, by the death of his father on the 4th of August 1066. He had been crowned at Reims, in the presence of a number of magnates, on the 23rd of May 1050. Philip passed most of his early years in and around Paris, where the castles of lawless barons, such as that of Monthléry, threatened even his personal safety. His minority came to an end in 1066. In the long reign that followed he showed no great ability or energy, and a looseness of morals which embroiled him with the Church. Before he was fifty years of age he became "fond of nothing but good cheer and sleep." But he increased the lands of his house around Paris, maintained order in them, and held his own against William I. and William II. of England, whose power in France far exceeded his own. This he accomplished for the most part by taking advantage of the quarrels among his vassals. When Baldwin VI. of Flanders died, in 1070, his son was attacked by his uncle Robert the Frisian, count of Holland. Philip interfered, at the prayer of Arnulf's mother, Richildis; but the allies were defeated near Cassel on the 22nd of February 1071 and Arnulf slain. After a second war peace was sealed, apparently, by the marriage of Philip to Robert's step-daughter Bertha, daughter of Gertrude of Saxony and Florence, count of Holland. In 1074 a new rupture led to Philip seizing Corbie, part of the dower of his aunt Adele, who had married Baldwin IV. of Flanders. By this he secured a sort of outpost in the direction of Flanders. The other main episodes of his reign were the quarrel over the Angevin inheritance and his wars with the dukes of Normandy. In the struggle between Fulk Rechin and his brother Robert over the inheritance of their uncle, Geoffroy Martel (d. 1060), count of Anjou, Philip received from Fulk in 1069, as the price of his neutrality, Château Landon and the Gatinais. This acquisition linked the county of Sens, acquired in 1055, with the rest of the domain round Paris, Melun and Orléans. War with William I. was chronic but intermittent. In 1076 Philip forced him to raise the siege of Dol in Brittany. Peace was made in 1077, and in December 1079 they together besieged Robert Curthose in the castle of Gerberoy. On the 8th of May 1080 the siege was raised and peace made. War with William began again in 1081 over the county of Vexin, which Philip had seized on the retirement of its count, Simon of Valois, to a monastery in 1076. William demanded the residence in the manor, and Philip, by the cession of Pontoise, Chaumont-en-Vexin and Mantes, but even after sacking Mantes in the same year. In 1098 there was war between Philip and William Rufus in both Maine and the Vexin. William came in person from Maine to lead the attack in the Vexin in September, and crossed the Seine, penetrating to within 30 m. of Paris on the west; but the campaign brought no results. In his last years Philip left the duty of repelling the attacks of his Norman and other enemies to his son Louis, associating him with himself, as "king-designate," some time between the 24th of May 1098 and the 25th of September 1100. It was his second marriage which was the cause of Philip's greatest difficulties. On the 15th of May 1092 he carried off Bertrada, daughter of Simon, baron de Montfort, wife of Fulk Rechin, and prepared to marry her, though his wife Bertha was still living. The bishops, headed by Ivo, bishop of Chartres, refused to attend the ceremony of marriage, but one was found to perform it. Philip's open simony had long been a cause of friction with the papacy. When he added bigamy and adultery, Urban II. excommunicated him. The bishop of Chartres, in consequence, refused to levy his vassals to help Philip's ally, Robert, duke of Normandy, against his brother William in 1094. Bertha died in that year, but Fulk was still living, and the sentence was renewed at the council of Autun on the 15th of October. Philip replied by summoning the bishops to Paris to try Ivo of Chartres for treason. He gained a respite from the papal sentence by promises of submission, but the sentence was renewed by Urban at the council of Clermont in 1095, in 1097, and at Poitiers in 1101, despite the protest of William IX., count of Poitiers, who entered the church with his knights to prevent his suzerain from being excommunicated on his lands. Philip was reconciled with the Church in 1104, and took an oath not to have any converse or society with Bertrada except in the presence of "non-suspect" persons. But they seem to have gone on living together, and even visited Fulk Rechin (Bertrada's husband) in company on the 15th of October 1106. Philip died at the end of July 1108.

His reign is chiefly remarkable for the steady growth of the royal domain. In addition to the gains mentioned, he bought in 1101 a large slice of territory, including Bourges and Dun-le-Roi, from Eudes Arpin, viscount of Bourges, who was going on the crusade; and toward the end of his reign took Monthléry, whose lord beat the southern approach to Paris. By his first queen he had four children: Louis VI., who succeeded him; Henry, who died young; Charles; and Constance, who married Hugh I., count of Champagne, and later Bohemond I., prince of Antioch. By Bertrada de Montfort he had three children: Philip, count of Montes; Fleurie or Florus, who married the heiress of Nangis; and Cecilia, who married, first Tancred, prince of Galilee and Antioch, and secondly Pons de Saint Gilles, count of Tripoli.

PHILIP II. (1165-1223), known as PHILIP AUGUSTUS, king of France, son of Louis VII. and Adela, daughter of Theobald II., count of Champagne, was born on the 21st of August 1165. On the 1st of November 1179 he was associated with his father as king by being crowned at Reims, and at once his father's illness threw the responsibility of government on him, the death of Louis on the 19th of September 1180 leaving him sole king.

The boy-king found himself and his kingdom in a difficult and humiliating position. His long strip of royal domain was hemmed in by the Anglo-Norman Empire on the west and by the kingdom of Arles on the south-east. Henry II. of England was feudal lord of the greater part of France, practically all west of a line from Auxerre to Poitiers; and Philip had to hold more than half-way across to the Mediterranean, while at one point it nearly touched the Rhone. Philip's predecessors had consolidated the Capetian power within these narrow limits, but he himself was overshadowed by the power of his uncles, William, archbishop of Reims; Henry I., count of Champagne; and Theobald V., count of Blois and Chartres. He secured an ally against them, and an addition to the royal domain, by marrying, on the 28th of April 1180, Isabella or Elizabeth, daughter of Baldwin V., count of Hainaut, and of Marguerite, sister of Philip of Alsace, the reigning count of Flanders, who ceded Arras, St. Omer, Aire and Hesdin, and their districts, as Isabella's dowry, a district of little importance, to secure the alliance. He made a treaty with Henry II. at Gisors, and his reign thus opened auspiciously. But from 1182 to 1185 he had to struggle against a feudal league of his Champagne uncles and other great
PHILIP II. (FRANCE) 379

barons, whose most active member was Stephen I., count of
Sançere (1152-1191). Though attacked from both north and
south, the king's activity enabled him to compel the count
of Sançere to implore peace in 1187. Cotton the death of Isabel of
Vermandois, with the Count Philip of Flanders, in 1182, Philip
claimed Vermandois and seized Chaâteau and St. Quentin,
and forced his father-in-law, Baldwin of Hainaut, to support him
by threatening to divorce Queen Isabel. The count of Flanders
was obliged to sign the treaty of Boves in July 1185, which gave
the king, in addition to the expectation of Artois, his wife's
dower, sixty-five castles in Vermandois and the town of Amiens.
By 1186 Hugh, duke of Burgundy, the only member of the
coalition not yet subdued, was forced to submit. Then, secure
at home, the king turned against Henry II., and by the truce of
Châteauroux in June 1187, gained Issoudun and the seigniory of
Fréteval in the Vendôme. The war of 1187 went well. Philip
assembled an army in 1188 to invade Normandy, descending
Gisors and the conclusion of the marriage which had been
arranged between his sister Alice and Richard of England,
who had meanwhile deserted his father. But the news came that
Saladin had taken Jerusalem and Richard took the cross.
Shortly afterwards Philip took advantage of a rising against his
quondam friend Richard, who was duke of Aquitaine, to seize
the county of Berry. At a conference at Bonnoublin in the
18th of November Richard again abandoned his father, and after
a second conference at La Ferté Bernard, Philip invaded Maine
and forced Henry II. to conclude the treaty of Azay on the 4th of
July 1189, by which the English king did homage and gave
arender the territories of Gracy and Issoudun. Henry died two
days later. Pledges of mutual good faith and fellowship were
renewed between Philip and Richard of England on the 30th of
December 1189, and they both prepared to go on the crusade.
Before setting out Philip arranged for the government of
France during his absence by his famous testament of 1190, by
which he proposed to rule France as far as possible from Palestine.
The power of the regents, Adela, the queen-mother, and William,
archbishop of Reims, was restricted by a council composed mostly
of clerks who had the king's confidence. An annual report on
the state of the kingdom was to be sent him. On the way to
Palestine the two kings quarrelled. At the siege of Acre Philip
fell ill, and on the 22nd of July, nine days after its fall, he an-
nounced his intention of returning home. He reached Paris at
Christmas 1191, having concluded on his way an alliance with
the emperor Henry VI. against Richard, despite his pledges not
to molest his lands. When Leopold I., duke of Austria, took
Richard prisoner and delivered him to the emperor, Philip had
his utmost by offers of money to prolong his captivity, and,
allied with the English king his brother John, attacked Richard's
domains, but upon Richard's return the Normans rallied enthusi-
aastically to his aid. Philip was defeated at Fréteval on the 3rd of
July 1194, but he continued the war, generally with ill success,
for the next five years. At Acre a formidable coalition was formed
against him, including Baldwin IX., count of Flanders and Hain
aut, Renaud of Dammartin, count of Boulogne, Louis, count of
Blois, and Raymond VI., count of Toulouse. In Germany, Otto
of Brunswick, afterwards the emperor Otto IV., allied himself
with Richard, with Philip was supported by Otto's rival, Philip
of Swabia. Richard's death, in April 1199, removed his arch-
enemy, and Richard's successor, John, concluded the treaty of
Le Goulet with Philip on the 22nd of May 1200, ceding to him
the county of Evrux, Gracy and Issoudun, and the suzerainty of
Berry and Auvergne. John renounced his suzerainty over
Brittany and the guardianship of his nephew, Arthur; he engaged
not to aid the count of Flanders or Otto IV. without Philip's
consent, paid him a relief of 20,000 marks, and recognized himself
as his vassal for his continental fiefs. Philip's son Louis, after-
wards Louis VIII., married Blanche of Castile, John's niece.
But in 1202 the war was renewed, John having seized some castles
from the family of Lusignan, whose head was the count of La
Marche, and taken for his queen a prospective bride, Isabelle
Taillefer, from Hugh, son of Hugh IX., count of La Marche. At
an interview at Le Goulet on the 25th of March, Philip demanded
the cession of Anjou, Poitou and Normandy to his ward, Arthur.
John refused; he was summoned to Paris before the royal
judges, and failing to appear was sentenced at the end of April
1202 to lose all his fiefs. Brittany, Aquitaine and Anjou were
conferred on Arthur. Philip invaded Normandy, took Lyons-
la-Forêt and Eu, and, establishing himself in Gournay, besieged
Arques. But John, joined by William des Roches and other
lords of Maine and Poitou, jealous at the increase of Philip's
power, defeated and took Arthur prisoner at Mirebeau. Philip
abandoned the siege of Arques in a fit of fury, marched to the
Loire, burning everywhere, and then returned to Paris. But
John soon alienated the Poitevin barons, and William des
Roches signed a treaty with Philip on the 22nd of March 1203.
Then Philip continued his great task, the conquest of Normandy,
capturing the towns around the fortress of Château-Gaillard which
was occupied by the English, and the conquest of the valley of the
Seine. Pope Innocent III. tried to bring peace, but the peace of
Jarnac was concluded, and after murdering Arthur of Brittany John took refuge
in England in December 1203. The fall of Château-Gaillard, after
a siege which lasted from September 1203 to April 1204, decided
the fate of Normandy. Rouen, bound by ties of trade to Eng-
land, resisted for forty days; but it surrendered on the 24th of
June 1204. The conquest of Maine, Touraine, Anjou and Poitou
in 1204 and 1205 was little more than a military promenade,
though the castles of Loches and Chinon held out for a year.
Philip secured his conquest by lavishing privileges on the con-
vents and towns. He left the great lords, such as William des
Roches, in full possession of their feudal power. In 1206 Philip
marched through Brittany and divided it amongst his adherents.
A truce for two years was made on the 26th of October 1206 by
which John renounced all claims in Normandy, Maine, Brittany,
Touraine and Anjou, but it did not last six months. Then
Poitou was thoroughly subdued, and another truce was made in
1208, little more than southern Saintonge and Gascony being left
in the hands of John. Philip had reduced to a mere remnant
the formidable continental empire of the Angevins, which had
threatened the existence of the Capetian monarchy.
Philip then undertook to invade England. In the assembly of
Soissons on the 8th of April 1213 he made every preparation
for carrying out the sentence of deposition pronounced by the
pope against John. He had collected 1500 vessels and summoned
all his barons when Innocent III., having sufficiently frightened
John, sent Pandulf with the terms of submission, which John
accepted on the 13th of May.
Disappointed of his hopes of England, Philip turned his arms
against Ferdinand, count of Flanders. Ferdinand, son of
Sancho I., king of Portugal, owed his county to Philip, who,
hoping to find him a docile protégé, had married him to Jeanne,
heirless of Flanders, daughter of Count Baldwin IX., who became
emperor of the East, using the weak Philip of Namur, her guar-
dian, to accomplish that end. They were married on January 1212.
On the marriage of Louis, afterwards Louis VIII.,
seized Aire and St Omer in right of his mother, Isabella,
and on this account Ferdinand refused his feudal duty in the English
expedition. Moreover, the trade interests of his subjects, who
got their raw wool from England, drew him to an alliance with
England. Philip's attack brought this about on the 22nd of
May 1213. He invaded Flanders and took the chief towns
within a week; but he had part of his fleet burned by the English
at Damme, and had to burn the rest to save it from falling into
their hands. He returned to Paris, and Ferdinand retook most
of the towns which had been taken by the king. A war of fire
and pillage began, in which Philip and his son Louis burned their
way through Flanders, and Ferdinand did the same through
Artois.
In 1214 came the great crisis of Philip's life. All the forces
against which he had been struggling united to overwhelm him.
Paris was to be attacked from Flanders and Guienne at the same
time. A league including his rebel vassals, Renaud of Dammartin,
count of Boulogne, and Ferdinand, count of Flanders, with the
emperor Otto IV. and a number of German princes of the Rhine
region, had been formed in the north-east, while John of England
made one more attempt to recover his heritage at the head of an army of mercenaries aid by the fierce baronage of Poitou. John landed at La Rochelle on the 16th of February 1214, and was at first successful. On the 19th of June he laid siege to La Rochelle-

mésines, the fortress which defended Angers and commanded the Loire valley; but on the approach of a royal army under Prince Louis on the 2nd of July his forces were forced to risk a pitched battle, and he fled hastily to La Rochelle. The Angevin Empire in France was lost. Meanwhile Philip himself won his greatest victory at the bridge of Bouvines, among the morasses of Flanders. At first taken by surprise, he turned the abortive attack into a complete rout. Renaud and Ferdinand were taken prisoner, and Otto IV. fled from the battlefield. The army of the allies was utterly destroyed (July 27, 1214). Nothing shows the progress of the Capetian monarchy more than the enthusiasm and joy of the people of France, as described by William the Breton, over this crowning victory. The battle of Bouvines, a decisive battle for the history of Germany as well as for France and England, sealed the work of Philip Augustus. The expedition of his son Louis to conquer England can hardly be considered as an incident of his reign, though he was careful to safeguard the rights of the French Crown. More important was the Albigensian crusade, in which he allowed Louis to take part, though he himself, preoccupied with the king of England, had refused time after time to do anything. He treated Simon de Montfort as if he were a royal baili; but it was not in virtue of any deep-laid scheme of his that in the end Amaury de Montfort, Simon’s son, resigned himself to leave his lands to the Crown of France, and gave the Crown a power it had never before possessed in Languedoc.

Even more than by his conquests Philip II. marks an epoch in French history by his work as an organization and statesman. He surrounded himself with clerks and legists of more or less humble origin, who gave him counsel and acted as his agents. His bailis, who at first rather resembled the itinerant justices of Henry II. of England, were sent into the royal domain to supervise the conduct of the prévôts and hear complaints, while in the newly acquired lands in the south local feudal magnates were given similar powers with the title of seigneurial. Feudal service was more and more complicated for by a money payment, while additional taxes were raised, all going to pay the mercenaries with whom he fought Richard I. and John. The Châtel, system of the seigneurie, by which abbey, towns or lay vassals put themselves under the special protection of the king, and that of pariège, by which the possessor surrendered half the interest in his estate to the king in return for protection or some further grant, increased the royal power. The small barons were completely reduced to submission, whilst the greater feudalatories could often appoint a castellan to their own castles only after he had taken an oath to the king. Philip supported the clergy against the feudal lords, and in many cases against the burghers of the towns, but rigidly exacted from them the performance of their secular duties, ironically promising to aid the clergy of Reims, who had failed to do so, “with his prayers only,” against the violence of the lords of Rethel and Roucy. He clung to his right of regal, or enjoyment of the revenues of bishops during their vacancy, though it was at times commuted for a fixed payment. The attempt to raise a tithe for the crusade in 1189 failed, however, before a general resistance owing to an unfair assessment.

It has been said with some justice that Philip II. was the first king of France to take the bourgeoisie into partnership. He favoured the great merchants, granting them trade privileges and monopolies. The Jews he protected and plundered by turns, after the fashion of medieval kings. Amongst the subject towns administered by prévôts, a great extension of the “custom of Lorraines” took place during his reign. But it is as the ally and protector of the communes that he takes his almost unique place in French history. Before him they were resisted and often crushed; after him they were exploited, oppressed, and finally destroyed. In the case of Sensis he extended the jurisdiction of the commune to all crimes committed in the district. It is true that he suppressed some communes in the newly conquered fiefs, such as Normandy, where John had been prodigal of privileges, but he erected new communes in his own private domain, quite contrary to the custom of other kings. He seems to have regarded them as a kind of garrison against feudal unrighteousness, while the rents they furnished increased his financial resources. He could make the communes a tool of state, however, except Peronne, which received a maximum of political independence, the twenty-four electors, who named the jures and other officers, being elected by the corps de métiers.

The newly organized powers of the Crown were in evidence everywhere, interfering in the family affairs of the great feudalatories and taking advantage of minorities, such as that of Theobald IV. of Champagne. The great feudalatories accepted his legislation on doner in 1214 and 1219 and the établissement of 1209 making co-heirs of fiefs hold direct from the king and not from one of their number. The Tournois was substituted for the Angevin money in Normandy after 1204. The army which safeguarded this absolute monarchy consisted chiefly of mercenaries. The old feudal est was but rarely convoked. The communes, though they appear as taking part in the battle of Bouvines, compounded for their service by a money payment as early as 1194. Philip’s policy of building up a strong monarchy was pursued with a steadiness of aim which excluded both enthusiasm and scruple. But he seems to have prided himself on a certain humanity, or even generosity of temper, which led him to avoid putting his enemies to death, though he did not scruple to condemn Renaud of Dommanin to the most inhuman of imprisonments. He was impulsive and could display extraordinary activity at times, but he acted also with caution. He shrank from no trickery in carrying out his ends, and had no room for pity. He could not even trust his own son with any power, and was brutal in his relations with his queen, Ingeborg. He is described by Païn Gâtineau as “a well-knit, handsome man, bald (from his illness at Acre), of agreeable face and ruddy complexion, loving good cheer, wine and women. Generous to his friends, he was miserly to those who displeased him; very skilled in the art of the engineer, catholic in his faith, far-seeing, obstinate in his resolution. His judgment was sound and quick. He was also quick in his anger, but easily appeased.” As the result of his steadiness of aim and patient sagacity, at the end of his reign the royal domain extended from the frontier along both royal authority. Artois, the Amienois, Valois, Vermandois, the greater part of the Beauvaisis, Normandy, Maine, Anjou, Touraine, and an important part of Poitou and Saintonge, were added to the domain during his reign. The number of prévôts was increased from thirty-eight to ninety-four, and the royal revenue increased from 19,000 livres a month to 1200 livres a day.

Philip Augustus died on the 14th of July 1223. He was thrice married. His first wife, Isabella, by whom he had one son, Louis, died in 1189 or 1190. After her death he married Ingeborg or Ingeborg (q.v.), daughter of Valdemar I. of Denmark. This unlucky marriage was negotiated, it is said, chiefly to acquire the old claims of Denmark over England, to be used as a weapon against Richard I. However that may be, he soon repudiated this Danish princess, for whom he seems to have conceived an unconquerable aversion on the very morrow of his marriage to her, and in 1166, in defiance of the pope, who had refused to nullify his union with Ingeborg, married Agnes, daughter of Bertold IV., duke of Meran. This led to his excommunication and brought the interdict upon France, and did more to weaken him than any other act of his. In 1200 he was forced to put away Agnes and to recognize Ingeborg as his lawful wife, but he kept her in prison until 1223. By Agnes (d. 1201) he had a son Philip, called “the Great,” count of Clermont and a daughter Mary, who married Philip, count of Namur (d. 1212), and then Henry II., duke of Brabant. Ingeborg lived until 1236.

See A. Luchaire in E. Lavisse’s Histoire de France, tome iii. 53-264 (Paris, 1904), and literature there indicated; L. Desirée, Catalogue des actes de Philippe Auguste (Paris, 1856 and 1901); A. Cartellieri, Philippe II. August, Bd. I. Bis zum Tod Ludwigs VII.
PHILIP III. (1245-1285), surnamed "the Bold" (le Hardi), king of France, son of Louis IX. and Margaret, daughter of Raymond-Bérenger IV., count of Provence, was born on the 3rd of April 1245. His funeral monument at St Denis depicts a man with beardless, square-cut features, but lacking character and animation. The authenticity of this effigy is fairly well borne out by what is known of him from other sources. He had many of the virtues of St Louis, but neither decision of character nor devotion to duty. He was pious, charitable, of unimpeachable morality, quick-tempered but placable, no great scholar, and only energetic as a hunter. The absence in him of the qualities that fit a man to rule made his court the arena of intriguing factions, which in reality ruled France during his reign of fifteen years. Matthew of Vendôme, abbot of St Denis, an old servant of Louis IX., acted as Philip's counsellor, so the chroniclers state, throughout the reign; but he is only a shadowy figure, and it is difficult to reconcile the statement that "everything was done according to his will" with the knowledge fact that he was probably without administration, and not policy, that Matthew was chiefly concerned. In one instance at least his advice was openly flouted. Coming to the throne by the death of his father on the 25th of August 1270, Philip began his reign by falling entirely under the influence of Pierre de la Brosse, who had been surgeon and valet-de-chambre to his father, upon whom he lavished lands and honours, making him lord (sicur) of Langeais, Chartillon-sur-Indre and Damville. Even Edward I. of England and William Dampierre, count of Flanders, strove to win his favour by gifts. But his fall was assured when Philip, who in 1271 lost his first wife, Isabella, daughter of James I., king of Aragon, married in 1274 Marie, daughter of Henry III., duke of Brabant. She was young and beautiful, and supplied a centre round which those who wished the downfall of the favourite grouped themselves. In June 1278 he was charged with various crimes, including one of poisoning the king's eldest son, and hanged at Montfaucon. His death left the parties of Marie, the queen, and Margaret, the queen-mother, to struggle for the mastery. The first subject of dispute was the inheritance of the count of Provence, Raymond-Bérenger IV., father of Margaret and of Eleanor, wife of Henry III. of England. Upon his death, in 1245, his youngest daughter, Beatrice, wife of Charles of Anjou, the king would not acknowledge his legitimate right to his brother, who claimed some portion of them for themselves. In 1281 war nearly broke out on this question. Margaret and her friends formed the league of Mâcon against Charles of Anjou, but the king managed to keep them at peace. The settlement of the claims of the king of England in Aquitaine by the treaty of Amiens in 1279 was a victory for the party of Margaret. Agenais and southern Saintonge, which fell to the Crown by the death of Alfonso of Poitiers in 1276, as part of his vast possessions in Aquitaine and Languedoc, were ceded to Edward I. of England in accordance with the treaty of Paris 1259. Another portion of the heritage of Alfonso, the Venaisin, was ceded to Edward in return for Edward's personal allegiance and the strokes of Charles of Anjou directed Philip's policy. He secretly urged his nephew's candidature for the imperial crown, left vacant by the death of Richard of Cornwall, king of the Romans, in 1272, but without success. In May 1275 the party of Marie secured for Philip, the king's second son, the hand of Jeanne, the heiress of Navarre and Champagne, along with the guardianship of the kingdom of Navarre during the minority of Jeanne. But early in 1276 Jeanne's mother, Blanche, the widow of Henry III. of Navarre and Champagne, married Edmund, first earl of Lancaster, brother of Edward I.; and she and her English husband kept Champagne until, in 1284, Jeanne came of age. A expedition of Philip against Castile in aid of the children of his sister, Blanche, proved abortive. Regardless of this warning, he was induced in 1284 to take up the quarrel of his uncle Charles in Sicily, after the Sicilian Vespers in 1282. Two assemblies of barons and prelates were held at Bourges in November 1283 and February 1284, to deliberate on the question. This was a mere matter of form; Marie of Brabant and her party had made the decision beforehand, and the crown of Aragon, which the French pope Martin IV. had declared forfeited by Peter, was accepted for Charles of Valois, Philip's third son. The project was strongly opposed by Matthew of Vendôme, who was in correspondence with the king of England on the subject. It was the first real venture of a political undertaking by the house of Capet outside France. It proved a disastrous failure. The French army laid siege to Gerona on the 26th of June 1285. The town surrendered on the 7th of September, but disease and the defeat of the fleet by the Aragonese navy at Las Farmiguas Islands led to a retreat, during which, on the 5th of October, the king died. In the same month the garrison placed at Gerona surrendered. It is typical of Philip's character and career that he should die thus, in an expedition undertaken against the interests of his kingdom, at the instigation of his ambitious uncle. Philip was twice married. On the 28th of May 1262 he married Isabella, daughter of James I., king of Aragon, who died in 1273, leaving three children: Louis, who died in 1276; Philip, born in 1268; Charles of Valois, born on the 12th of March 1270; and Robert, who died young. By his second wife, Marie (d. 1322), daughter of Henry III. of Brabant, whom he married in 1274, he had three children: Louis, count of Evreux; Margaret; who married in 1290 Edward I., king of England; and Blanche, who married Rudolph III., duke of Austria.

PHILIP IV. (1268-1314), called "le Bel" or "the Fair," king of France, was the son of Philip III. and his wife, Isabella of Aragon. His reign, which began in October 1285, is one of the most momentous in the history of medieval Europe, yet it belongs rather to the history of France and to that of the papacy than to the biography of the king. Little is known of the personal part played by Philip in the events associated with his name, and later historians have been divided between the view which paints him as a faithful and conscientious statesman, or which paints him as a master of statecraft who, under a veil of phlegmatic indifference and pious sentiment, masked an inflexible purpose, of which his ministers were but the spokesmen and executors. The first view seems to be borne out by the language of contemporary chroniclers. To his enemy, Bernard Saisset, he was neither man nor beast, but a statue, "the handsomest man in the world, but unable to do anything but stare fixedly at people without saying a word." Guillaume de Nogaret, his minister, draws a far more flattering picture, enlarging on his charm, his amiability, his modesty, his charity to all men, and his piety; and the traits of this over-coloured portrait are more or less repeated by his 13th-century biographer, Farmiguas. There is, however, no word of any qualities of will or initiative. All of which suggests a personality mentally and physically phlegmatic, a suggestion strengthened by the fact that Bartholomaeus de Neoastro (quoted by Wenck) describes him as corpulent in 1290.

Yet this was the king who with equal implacability brought the papacy under his yoke, carried out the destruction of the powerful order of the Temple, and laid the foundations of the national monarchy of France. In this last achievement Professor Finke finds the solution of a problem which Langlois had declared to be insoluble. In 1292, in the midst of a hostile assembly, Philip cursed his sons should they consent to hold the Crown of France in common. Yet God; for no one but he sees the key to his character. "Philip was not a man of violent initiative, the planner of daring and fateful operations; otherwise there

1 Wenck, p. 49.
would have been some signs of it. His personality was that of a well-instructed, outwardly cold, because cool and calculating man, essentially receptive, afores only one idea: the highest possible development of the French monarchy, both internally and externally, as against both the secular powers and the Church. His merit was that he carried through this idea in spite of dangers to himself and to the state. A resolution once arrived at he carried out with iron obstinacy.” Certainly he was no roi fainéant. His courage at the battle of Mons-en-Pévèle was the admiration of friend and foe alike. It was against the advice of his tutor, Aegidius Colonna, that on coming to the throne he chose as his counsellors men of the legal class, and the names of his great ministers—Guillaume de Nogaret, Enguerrand de Marigny, Pierre Flotte (d. 1302)—attest the excellent quality of his judgment. He was, too, one of the few monarchs who have left to their successors reasoned programmes of reform for the state.

The new materials from the Aragonese archives, published by Finke, give the same general impression of “uncanny” reticence on Philip’s part; when other contemporary kings would have spoken he keeps silence, allowing his ministers to speak for him.

Isolated passages in some of the Aragonese letters included in the collection, however, throw a new light on contemporary estimate of his character, describing him as all-powerful, as “pope and king and emperor in one person.”

The reign of Philip IV. is of peculiar interest, because of the intrusion of economic problems into the spheres of national policy and even of religion. The increased cost of government and the growing wealth of the middle class, rather than the avarice of the king and the genius of his ministers, were responsible for the genesis and direction of the new order. The greatest event of the reign was the struggle with Pope Boniface VIII. (g.v.). The pope, in his opposition to the imposition of royal taxation upon the clergy, went so far in the bull Clerici laicos of 1306 as to forbid any lay authority to demand taxes from the clergy without his consent. When Philip retaliated by a decree forbidding the exportation of any coin from France, Boniface gave way to save the papal ducats, and the bulls issued by him in 1307 were a decided victory for the French king. Peace between the two potentates followed until 1311. After the arrest, by Philip’s orders, of Bernard Saisset (g.v.), bishop of Pamiers, in that year, the quarrel flamed up again; other causes of difference existed, and in 1302 the pope issued the bull Unam sanctam, one of the most extravagant of all statements of papal claims. To ensure the support of his people the king had called an assembly of the three estates of his kingdom at Paris in April 1302; then in the following year Guillaume de Nogaret seized the person of the pope at Anagni, an event immortalized by Dante. Boniface escaped from his captors only to die (October 11), and the short pontificate of his saintly successor, Benedict XI., was occupied in a vain effort to restore harmony to the Church. The conclavists that met at Perugia on his death was divided between the partisan of the irreconcilable policy of Boniface VIII. and those of a policy of compromise with the new state theories represented by France. The election was ultimately determined by the diplomacy and the gold of Philip’s agents, and the new pope, Clement V., was the weak-willed creature of the French king, to whom he owed the tiara. When in 1306 the pope installed himself at Avignon, the new relation of the papacy and the French monarchy was patent to the world. It was the beginning of the long “Babylonian captivity” of the popes. The most notable of its first-fruits was the hideous persecution of the Templars (g.v.), which began with the sudden arrest of the members of the order in France in 1307, and ended with the suppression of the order by Pope Clement at the council of Vienne in 1313.

It is now tolerably clear that Philip’s motives in this sinister proceeding were lack of money, and probably the deliberate wish to destroy a body which, with its privileged position and international financial and military organization, constituted a possible menace to the state. He had already persecuted and plundered the Jews and the Lombard bankers, and repeated recourse to the debasing of the coinage had led to a series of small risings. But under his rule something was done towards systematizing the royal taxes, and, as in England, the financial needs of the king led to the association of the people in the work of government.

In 1294 Philip IV. attacked Edward I. of England, then busied with the Scottish War, and seized Guienne. Edward won over the counts of Bar and of Flanders, but they were defeated and he was obliged to make peace in 1297. Then the Flemish cities rose against the French royal officers, and utterly defeated the French army at Courtvrai in 1302. The reign closed with the French position unimproved in Flanders, except for the transfer to Philip by Count Robert of Lille, Douai and Béthune, and their dependencies. Philip died on the 29th of November 1314. His wife was Jeanne, queen of Navarre (d. 1304), through whom that country passed under the rule of Philip on his marriage in 1284; three of his sons, Louis X., Philip V. and Charles IV., succeeded in turn to the throne of France, and a daughter, Isabella, married Edward II. of England.

See the Chronique de Geoffrey of Paris, edited by M. Bouquet, in vol. xxii. of the Recueil des historiens des Gaules et de la France. Of the later historians see Philippe le Bel (1861); G. Digard, Philippe le Bel et le Saint-Siège (1900); C. V. Langlois in E. Lavisse’s Histoire de France, vol. iii. (1901); K. Wenck, Philipp der Schone von Frankreich (Marburg, 1905); H. Finke, Papsttum und Untergang des Tempelordens, 2 vols. (Münster i. W. 1897), esp. i. ch. ii.

Philip V. (c. 1294-1322), “the Tall,” king of France, second son of Philip the Fair and Jeanne of Navarre, received the county of Poitiers as an appanage, and was affianced when a year old to Jeanne, daughter and heiress of Otto IV., count of Burgundy. The marriage took place in 1307 when he was thirteen years of age. When his elder brother, Louis X., died, on the 5th of July 1316, leaving his second wife, Clemence of Hungary, with child, Philip was appointed regent for eighteen years by the parliament of Paris, even in the event of a male heir being born. Clemence’s son, born on the 13th of November, lived only four days, and Philip immediately proclaimed himself king, though several of the great barons declared that the rights of Jeanne, daughter of Louis X. by his first wife, Margaret of Burgundy, ought to be examined before anything else was done. The coronation at Reims, on the 9th of January 1317, took place with the gates of the city closed for fear of a surprise. The states-general of the 2nd of February 1317, consisting of the nobles, prelates, and the burgesses of Paris, approved the coronation of Philip, swore to obey him, and declared that women did not succeed to the Crown of France. The university of Paris approved this declaration, but its members did not take the oath. The Salic law was not involved, and it was later that the lawyers of the 14th century tried to accept the principle to an article of the Salic law, which accords inheritance in land (i.e. property) to males. In the Frankish law the article refers to private property, not to public law. The death of Philip’s son Louis, in 1317, disarmed the opposition of Charles, count of La Marche, who now hoped to succeed to the Crown himself. Odo or Eudes IV., duke of Burgundy, was married to Jeanne, Philip’s daughter, and received the county of Burgundy as her dower. The barons all did homage except Edward II. of England, and Philip’s position was secured. The war with Flanders, which had begun under Philip IV. the Fair, was brought to an end by the 2nd of June 1320. The revolt of the Pastoureaux who assembled at Paris in 1320 to go on a crusade against the seneschal of Carmagnolle, whether they marched. One of the special objects of their hatred, the Jews, were also mutinied heavily by Philip, who extorted 120,000 livres from those of Paris alone. He died at Longchamp on the night of the 2nd of January 1322.

Philip was a lover of poetry, surrounded himself with Provençal poets and even wrote in Provençal himself, but he was also one of the most hard-working kings of the house of Capet. The
insecurity of his position made him seek the support of national assemblies and of provincial estates. His reign in some ways resembled that of Edward I. of England. He published a series of ordinances organizing the royal household and affecting the financial administration, the “parlement” and the royal forests. He abolished all garrisons in the towns except those on the frontier and provided for public order by allowing the inhabitants of his towns to arm themselves under the command of captains. He tried hard to procure a unification of coinage and weights and measures, but failed owing to the opposition of the estates, who were afraid of the new taxation necessary to meet the loss involved in raising the standard of the coinage, and who held to their local measures and currency partly from conservatism, partly as a relic of local liberty. Philip as a reformer was in many ways before his time, but his people failed to understand him, and he died under the reproach of extortion.

See P. Lehugueur, Histoire de Philippe le Long (Paris, 1897); E. Lavisse, Histoire de France (Tome III, 2); and sources indicated in A. Molinier, Répertoire des sources de l’histoire de France (Paris, 1903).

**PHILIP VI.** (1302-1350), king of France, was the son of Charles of Valois, third son of Philip III, the Bold, and of Margaret of Sicily, and was thus the nephew of Philip IV, the Fair, whose sons, Louis X., Philip V. and Charles IV., died successively without leaving male heirs. He succeeded to the throne on the death of his cousin, Charles IV., in 1328. Before his accession Philip had enjoyed considerable influence, for he was count of Valois, Anjou, Maine, Chartres and Alençon. He had married in 1313 Jeanne (d. 1348), daughter of Robert II. of Burgundy, a determined woman who was long known as the real ruler of France. An expedition to Italy in 1319-20 against Galéas Visconti brought him little glory; he was more successful in a small expedition to Guienne, undertaken against a revolted vassal who was supported by the English.

When Charles IV. died, in February 1328, his wife was eneinte, and it became necessary to appoint a regency until the birth of the child, who would, if a son, succeed to the throne. At the assembly of barons called to choose a regent, Edward III. of England, the nephew and nearest male relation of Charles IV., put in a claim. Edward III., however, descended from the royal house of France by his mother Isabel, and the barons, probably actuated by an objection to the regency of an English king, decided that neither a woman, “nor by consequence her son, could succeed to the kingdom of France,” and Philip, Valois, in spite of his belonging to a junior branch of the family, was elected regent. On the birth of a girl to the queen widow the regency naturally led to the throne of France, and Philip was crowned at Reims on the 20th of May 1328. Navarre had not accepted the regency, that kingdom being claimed by her husband for Jeanne, countess of Evreux, the eldest daughter of Louis X., the count of Evreux himself being, like Philip of Valois, a grandson of Philip the Bold. The new king secured the friendship of the count by allowing Jeanne’s claim to Navarre, in return for a renunciation of any right to Champagne. Edward III. of England, after more than one citation, tendered verbal homage for part of Guienne at Amiens in 1329, but he declined to place his son, the young Edward, in the hands of the regent to formally acknowledge him as his liege lord. Two years later, however, he forwarded the acknowledgment by letters patent. Meanwhile Philip VI. had won a victory, which he turned into a massacre, at Cassel (August 23, 1328) over Bruges and the other towns of West Flanders, which under the leadership of Jakob van Artevelde had thrown off the authority of their count, Louis of Nevers. The count of Flanders was reinstated, and maintained his authority by a reign of terror.

Much harm was done to Philip VI.’s authority by the scandal arising out of the prosecution of Robert of Artois, count of Beaumont, who was the king’s brother-in-law. The count had presented to the parlement of Paris forged deeds in support of his claim to the county of Artois, held by his aunt, Mahaut, countess of Burgundy. The sudden death of Mahaut, and of her daughter and heiress, Jeanne, widow of Philip V., lent colour to other suspicions, and Robert was driven from France and his goods confiscated. He found refuge, first in Brabant and then at the English court, where he was received as a relative and a victim of false accusations.

Philip VI. enjoyed powerful alliances. In Italy he was allied with his uncle, Robert of Anjou, king of Sicily, and with his former enemy, Galéas Visconti; in the north with the duke of Brabant and the princes of the Netherlands; on the east with the reigning princes of Lorraine and Savoy; with the king of Bohemia and with Pope John XXII. at Avignon, and his successor, Benedict XII. In 1336 it seemed that the Crusade, for which Philip VI. had long been preparing, would at last start; but the relations with Edward III. of England, which had always been strained, became worse, and within a year France was embarked on the struggle of the Hundred Years’ War. The causes which led to war, the conflict for commercial supremacy in Flanders, disputed rights in Guienne, the help given by France to the Scots, and the unnatural situation of an English king who was also a vassal of the French Crown are dealt with elsewhere (see France: History). The immediate rupture in Flanders was due chiefly to the tyranny of the count of Flanders, Louis of Nevers, whom Philip VI. had reinstated. Edward III. had won over most of Philip’s German and Flemish allies, and the English naval victory at Sluys (June 24, 1340), in which the French fleet was annihilated, effectually restored Edward preponderance in Flanders. A truce followed, but this was disturbed after a short duration by the disputed succession to the duchy of Brittany. Edward III. supported John of Montfort; Philip IV. his own nephew, Charles of Blois. A truce made at Malestroit in 1343 at the invitation of the pope, was rudely broken by Philip’s violence. Olivier de Clisson, who with fourteen other Breton gentlemen, was suspected of intrigue with Edward III., was invited to a great tournament in Paris. On their arrival they were seized by Philip’s orders, and without form of trial beheaded. Then followed Edward III.’s invasion of Normandy and the campaign of Crecy (q.v.). Philip’s army was destroyed; he himself was wounded and fled from the field. He sought in vain to divert Edward from the siege of Calais by supporting the Scots in their invasion of England; but eventually a truce was arranged, which lasted until 1351. Philip VI. died at Nogent-le-Roi on the 12th of August 1350.

Philip VI. met his necessities by the imposition of the hated gabelle or salt tax, which was invented by his legal advisers. The value of the coinage fluctuated continuously, to the great hindrance of trade; although at a meeting of the States-General it was asserted that the king could levy no extraordinary taxes without the consent of the estates, he obtained heavy subsidies from the various provinces. Towards the close of his reign he acquired from Humbert II., comte de Vienne, the province of Dauphiné, and Montpellier from the king of Majorca. These acquisitions made the ultimate annexation of Provence a certainty. Philip married a second wife, Blanche of Navarre. By his first wife he left two sons—his successor, John II., and Philip of Orleans, count of Valois.

**PHILIP (c. 1177-1208).** German king and duke of Swabia, the rival of the emperor Otto IV., was the fifth and youngest son of the emperor Frederick I. and Beatrix, daughter of Renaud III., count of the Upper Bourgogne, and consequently brother of the emperor Henry VI. He entered the church, was made provost of Aix-la-Chapelle, and in 1199 or 1191 was chosen bishop of Würzburg. Having accompanied his brother Henry to Italy in 1191, Philip forsook his ecclesiastical calling, and, travelling again to Italy, was made duke of Tuscany in 1195 and received
PHILIP I.—II. (SPAIN)

an extensive grant of lands. In 1196 he became duke of Swabia, on the death of his brother Conrad; and in May 1197 he married Irene, daughter of the eastern emperor, Isaac Angelus, and widow of Roger II., king of Sicily, a lady who is described by Walther von der Vogelweide as the "rose without a thorn, the dew without guilt." Philip enjoyed his brother's confidence to a very great extent, and appears to have been designated as guardian of the young Frederick, afterwards the emperor Frederick II., in case of his father's early death. In 1197 he had set out to fetch Frederick from Sicily for his coronation when he heard of the emperor's death and returned at once to Germany. He appears to have desired to protect the interests of his nephew and to quell the disorder which arose on Henry's death, but events were too strong for him. The hostility to the kingship of a child was growing, and after Philip had been chosen as defender of the empire during Frederick's minority he consented to his own election. He was elected German king at Mühlhausen on the 8th of March 1198, and crowned at Mainz on the 8th of September following. Meanwhile a number of princes hostile to Philip, under the leadership of Adolph, archbishop of Cologne, had elected an anti-king in the person of Otto, second son of Henry the Lion, duke of Saxony. In the war that followed, Philip, who drew his principal support from south Germany, met with considerable success. In 1199 he received further accessions to his party and carried the war into his opponent's territory, although unable to obtain the support of Pope Innocent III., and only feebly assisted by his ally Philip Augustus, king of France. The following year was less favourable to his arms; and in March 1201 Innocent took the decisive step of placing Philip and his associates under the ban, and began to work energetically in favour of Otto. The two succeeding years were still more unfavourable to Philip. Otto, aided by Ottakar I., king of Bohemia, and Hermann I., landgrave of Thuringia, drove him from north Germany, thus compelling him to seek by abject concessions, but without success, reconciliation with Innocent. The submission to Philip of Hermann of Thuringia in 1204 marks the turning-point of his fortunes, and he was soon joined by Adolph of Cologne and Henry I., duke of Brabant. On the 6th of January 1205 he was crowned again with great ceremony by Adolph at Aix-la-Chapelle, though it was not till 1207 that his entry into Cologne practically brought the war to a close. A month or two later Philip was loosed from the papal ban, and in March 1208 it seems probable that a treaty was concluded by which a nephew of the pope was to marry one of Philip's daughters and to receive the disputed dukedom of Tuscany. Philip was preparing to crush the last flicker of the rebellion in Brunswick when he was murdered at Bamberg, on the 21st of June 1208, by Otto of Wittelsbach, count palatine in Bavaria, to whom he had refused the hand of one of his daughters. He left no sons, but four daughters; one of whom, Beatriz, afterwards married his rival, the emperor Otto IV. Philip was a brave and handsome man, and contemporary writers, among whom was Walther von der Vogelweide, praise his mildness and generosity.

See W. von Giesebrecht, Geschichte der deutschen Kaiserzeit, Bd. V. (Leipzig, 1888); E. Winkelmann, Philipp von Schwaben und Otto IV. von Braunschweig (Leipzig, 1873-1879); O. Abel, König Philipp der Hohenstaufen (Berlin, 1895); Regel (Reperiti, ed. by Ficker, 1882); R. Schwemer, Innocent III. und die deutsche Kirche während des Thronstreites von 1198-1208 (Strassburg, 1882); and R. Riant, Innocent III., Philippe de Souabe, et Boniface de Montferrat (Paris, 1873).

PHILIP I., the Handsome (1478-1506), king of Spain, son of the emperor Maximilian I., and husband of Joanna the Mad, daughter of Ferdinand and Isabella, was the founder of the Habsburg dynasty in Spain, and reigned from the 22nd of June 1478. In 1482 he succeeded to the Burgundian possessions of his mother Mary, daughter of Charles the Bold, under the guardianship of his father. In 1496 he married Joanna. The marriage was one of a set of family alliances with Austria and Portugal designed to strengthen Spain against France. The death of John, the only son of Ferdinand and Isabella, opened the succession to the Spanish Crown to Joanna. In 1502 she and her husband received the homage of the cortes of Castile and of Aragon as heirs. Philip returned to Flanders before the close of the year. His life with Joanna was rendered extremely unhappy by his infidelity and by her jealousy, which, working on her avaricious temperament, poisoned her incompatibility. The princess gave way to paroxysms of rage, in which she was guilty of acts of atrocious violence. Before her mother's death, in 1504, she was unquestionably quite insane, and husband and wife lived apart. When Isabella died, Ferdinand endeavoured to lay hands on the regency of Castile, but the nobles, who disliked and feared him, forced him to withdraw. Philip was summoned to Spain, where he was recognized as king. He landed, with his wife, at Corunna on the 28th of April 1506, accompanied by a body of German mercenaries. Father and son-in-law had interviews at Résenaal, near Pueblo de Sanabria, and at Renedo, the only result of which was an indecent family quarrel, in which Ferdinand professed to defend the interests of his daughter, who he said was imprisoned by his husband. A civil war would probably have broken out between them; but Philip, who had only been in Spain long enough to prove his incapacity, died suddenly at Burgos, apparently of typhoid fever, on the 25th of September 1506. His wife refused for long to allow his body to be buried or to part from it. Philip was the father of the emperors Charles V. and Ferdinand I.

PHILIP II. (1527-1598) king of Spain, was born at Valladolid on the 21st of May 1527. He was the son of the emperor Charles V., and of his wife Isabella of Portugal, who were first cousins. Philip received his education in Spain. His tutor, Dr Juan Martinez Pedernales, who latinized his name to Spanish, and who was also his confessor, does not appear to have done his duty very thoroughly. The prince, though he had a good command of Latin, never equalled his father as a linguist. Don Juan de Zuñiga, who was appointed to teach him the use of arms, was more conscientious; but he had a very poor pupil. From his earliest years Philip showed himself more addicted to the desk than the saddle and to the pen than to the sword. The emperor, who spent his life moving from one part of his wide dominions to another and in the camps of his armies, watched his heir's education from afar. The trend of his letters was to impress on the boy a profound sense of the high destinies to which he was born, the necessity for keeping his nobles apart from all share in the conduct of the internal government of his kingdom, and the wisdom of distrusting counsellors, who would be sure to wish to influence him for their own ends. Philip grew up grave, self Possessed and distrustful. He was beloved by his Spanish subjects, but utterly without the power of attracting men of other races. Though accused of extreme licentiousness in his relations with women, and though he lived for years in adultery with Doña Maria de Osorio, Philip was probably less immoral than most kings of his time, including his father, and was rigidly abstemious in eating and drinking. His power of work was unbounded, and he had an absolute love of reading, annotating and drafting despatches. If he had not become sovereign of the Low Countries, as heir of Mary of Burgundy through his father, Philip would in all probability have devoted himself to warfare with the Turks in the Mediterranean, and to the conquest of northern Africa. Unhappily for Spain, Charles, after some hesitation, decided to transmit the Netherlands to his son, and not to allow them to go with the empire. Philip was summoned in 1548 to Flanders, where he went unwillingly, and was ill regarded. In 1551 he was back in Spain, and intrusted with its government. In 1543 he had been married to his cousin Mary of Portugal, who bore him a son, the unhappy Don Carlos, and who died in 1545. In 1554, when Charles was meditating his abdication, he proposed to the position of Itamar to summoned Philip to Flanders again, and arranged the marriage with Mary, queen of England, who was the daughter of his sister Catherine, in order to form a union of Spain, the Netherlands and England, before which France would be powerless. The marriage proved barren. The abdication of his father on the 16th of January 1556 constituted Philip sovereign of Spain with its American possessions, of the Aragonese inheritance
in Italy, Naples and Sicily, of the Burgundian inheritance—the Netherlands and Franche Comté, and of the duchy of Milan, which his father separated from the empire for his benefit. It was a legacy of immense responsibilities and perils, for France was bound in common prudence to endeavour to ruin a power which encircled her on every side save the sea and threatened her independence. France was for a time beaten at the battles of St Quentin and Gravelines, and forced to make the Peace of Cateau Cambresis (April 2, 1559). But the death of Mary of England on the 17th of November 1558 had deprived Philip of English support. The establishment of Elizabeth on the English throne put on the line of all his scattered and another power, forced no less than France by unavoidable political necessities to be his enemy. The early difficulties of Elizabeth's reign secured him a deceitful peace on that side for a time. His marriage with Elizabeth of Valois on the 22nd of June 1559, and the approach of the wars of religion, gave him a temporary security from France. But the religious agitation was affecting his own Flemish possessions, and when Philip went back to Spain, in August 1559, he was committed to a life-long struggle in which he could not prove victorious except by the conquest of France and England.

If Philip II. had deserved his name of the Prudent he would have made haste, so soon as his father, who continued to intervene in the government from his retreat at Yuste in Extremadura, was dead, to relieve himself of the ruinous inheritance of the Low Countries. It was perhaps impossible for him to renounce his rights, and his education, co-operating with his natural disposition, made it morally impossible for him to believe that he could be in the wrong. Like the rest of his generation, he was convinced that unity of religion was indispensable to the maintenance of the authority of the State and of good order. Family pride, also, was carried by him to its highest possible pitch. Thus external and internal influences alike drove him into conflict with the Netherlands, France and England; with the first because political and religious discontent combined to bring about revolt, which he felt bound in duty to crush; with the second and third because they helped the Flemings and the Hollanders. The conflict assumed the character of a struggle between Protestantism and Roman Catholicism, in which Philip appeared as the champion of the Church. It was a part he rejoiced to play. He became, and could not but become, a persecutor in and out of Spain; and his persecutions not only hardened the obstinacy of the Dutch, but helped to exasperate the English, but they provoked a revolt of the Moriscos, which impoverished his kingdom. No experience of the failure of his policy could shake his belief in its essential excellence. That whatever dominates desire is the measure of his satisfaction, he was to test later on the inscrutable will of the Almighty and not on himself, were his guiding convictions, which he transmitted to his successors. The "service of God and his majesty" was the formula which expressed the belief of the sovereign and his subjects. Philip must therefore be held primarily responsible for the insane policy which brought Spain to ruin. He had a high ideal of his duty as a king to his own people, and had no natural preference for violent courses. The strong measures he took against disorderly elements in Aragon in 1591 were provoked by extreme misconduct on the part of a faction. When he enforced his claim to the crown of Portugal (1579–1581) he preferred to place his new subjects by paying attention to their feelings and their privileges. He even made dangerous political concessions to secure the support of the gentry. It is true that he was ready to make use of assassination for political purposes; but he had been taught by his lawyers that he was "the prince," the embodied state, and as such had a right to act for the public good, legibus solutus. This was but in accordance with the temper of the times. Coligny, Lord Burghley and William the Silent also entered into murder plots. In his private life he was orderly and affectionate to his family and servants. He was slow to withdraw the confidence he had once given. In the painful episode of the imprisonment and death of his firstborn son, Don Carlos, Philip behaved honourably. He bore the acute agony of the disease which killed him with many patience, and he died piously at the Escorial on the 13th of September 1598.

As an administrator Philip had all the vices of his type, that of the laborious, self-righteous man, who thinks he can supervise everything, is capable of endless toil, and jealous of his authority, and who therefore will let none of his servants act without his instructions. He set the example of the unending discussions in committee and boundless minute writing which finally choked the Spanish administration.

The Historie de Philippe II. of M. H. Forneron (Paris, 1881), contains many references to authorities and is exhaustive, but the author has some violent prejudices. Philip II., by Martin Hume (London, 1897), is more just in its treatment of Philip's personal character, and gives a useful bibliography. The main sources for the history and state papers of Philip II. are: Las generaux et contre-generaux et autres discours para la historia de Espana (Madrid, 1842, &c.), vols. i., iii., vii., xvi., xxiv., xl., xvii., cl., clix., cx., cxc. and others; L. P. Gachard, Actes des états généraux des Pays Bas, 1570–1586 (Brussels, 1861–1866); and the Calendars of State Papers, Foreign Series, Elizabeth (London, 1863–1901). See also Martin Hume, Two English Queens and Philip (1908).

PHILIP III. (1578–1621), king of Spain, son of Philip II. and his fourth wife, Anne, daughter of the emperor Maximilian II., was born at Madrid on the 14th of April 1578. He inherited the beliefs of his father, but no share of his industry. The old king had been deeply concerned for God, and had hoped to make Spain capable of governing his vast dominions, and had foreseen that Philip III. would be led by his servants. This calculation was exactly fulfilled. The new king put the direction of his government entirely into the hands of his favourite, the duke of Lerma, and when he fell under the influence of Lerma's son, the duke of Uceda, in 1585, he trusted himself and his states to the new favourite. The king's own life was passed amid court festivities, on which enormous sums of money were wasted, or in the practice of childish piety. It was said that he was so virtuous as hardly to have committed a venial sin. He cannot be justly blamed for having been born to rule a despotic monarchy, without even the capacity which would have qualified him to manage a small estate. He died at Madrid on the 31st of March 1621. The story told in the memoirs of the French ambassador Bassompierre, that he was killed by the heat of a brasero (a pan of hot charcoal), because the proper official to take it away was not at hand, is a humorous exaggeration of the formal etiquette of the court.

R. Watson and W. Thompson, History of Philip III. (1786), give the most available general account of his reign; see also the continuation of Mariana's History of Spain by Miliana (Madrid, 1800–1801).

PHILIP IV. (1605–1665), king of Spain, eldest son of Philip III. and his wife Margaret, sister of the emperor Ferdinand II., was born at Valladolid on the 8th of April 1605. His reign, after a few passing years of barren successes, was a long story of political and military decay and disaster. The king had been held responsible for the fall of Spain, which was, however, due in the main to internal causes beyond the control of the most despotic ruler, however capable he had been. Philip certainly possessed more energy, both mental and physical, than his father. There is still in existence a translation of Guicciardini which he wrote with his own hand in order to qualify himself for government by acquiring a knowledge of political history. He was a fine horseman and keen hunter. His artistic taste was shown by his patronage of Velasquez, and his love of letters by his favour to Lope de Vega, Calderon, and other dramatists. He is even credited, on fairly probable testimony, with a share at least in the composition of several comedies. His good intentions were of no avail to his government. Coming to the throne at the age of sixteen, he did the wisest thing he could by allowing himself to be guided by the most capable man he could find. His favourite, Olivares, was a far more honest man than the duke of Lerma, and was more fit for the place of prime minister than any Spaniard of the time. But Philip IV. had not the strength of mind to free himself from the influence of Olivares when he had grown to manhood. The amusements which the favourite had encouraged became the business of the
king's life. When, in 1643, the disasters falling on the monarchy on all sides led to the dismissal of Olivares, Philip had lost the power to devote himself to hard work. After a brief struggle with the task of directing the administration of the most extensive and the worst organized monarchy in Europe, he sank back into his pleasures and was governed by other favourites. His political opinions were those he had inherited from his father and grandfather. He thought it his duty to support the German Habsburgs and the cause of the Roman Catholic Church against the Protestants, to assert his sovereignty over Holland, and to extend the dominions of his house. The utter exhaustion of his people in the course of a hopeless struggle with Holland, France and England was seen by him with sympathy, but he considered it an unavoidable misfortune and not the result of his own errors, since he could not be expected to renounce his rights or to desert the cause of God and the Church. In public he maintained a bearing of rigid solemnity, and was seen to laugh only three times in the course of his life. But in private he indulged in horseplay and very coarse immorality. His court was grossly vicious. The early death of his eldest son, Baltasar Carlos, was unquestionably due to debauchery encouraged by the gentlemen entrusted by the king with his education. The lesson shocked the king, but its effect soon wore off. Philip IV. died broken-hearted on the 17th of September 1665, expressing the hope that his surviving son, Carlos, would be more fortunate than himself.

The best accounts of Philip IV. will be found in the "Estudios del reinado de Felipe IV.", by Don A. Canovas del Castillo (Madrid, 1889), and in the introduction, by Don F. Silvela to his edition of the "Cartas de Sor Maria de Agreda y del rey Felipe IV.", (Madrid, 1885-1886).

PHILIP V. (1663-1746), king of Spain, founder of the present Bourbon dynasty, was the son of the Dauphin Louis and his wife, Maria Anna, daughter of Ferdinand Maria, elector of Bavaria. He was born at Versailles on the 16th of December 1663. On the extinction of the male line of the house of Habsburg in Spain he was named heir by the will of Charles II. He had shared in the careful education given to his elder brother, Louis, duke of Burgundy, by Fénelon, and was himself known as duke of Anjou. Philip was by nature dull and phlegmatic. He had learnt morality from Fénelon's teaching, and showed himself throughout his life strongly adverse to the moral laxity of his brothers and most of the princes of his time. But his very domestic regularity caused him to be entirely under the influence of his two wives, Maria Louisa of Savoy, whom he married in 1702, and who died in February 1714, and Elizabeth Farnese of Parma, whom he married in December of the same year, and who survived him. He showed courage on the field of battle, both in Italy and Spain, during the War of the Spanish Succession, and was flattered by his courtiers with the title of El Anímose, or the spirited. But he had no taste for military adventure. If he had a strong passion, it was to provide for his succession to the throne of France, if his nephew, Louis XV., should die, and he indulged in many intrigues against the house of Orleans, whose right to the succession was supposed to be secured by Philip's solemn renunciation of all claim to the French throne, when he became king of Spain. It was in pursuit of one of these intrigues that he abdicated in 1724 in favour of his son Louis. But Louis died in a few months, and Philip returned to the throne. At a later period he tried to abdicate again, and his wife had to keep him in a species of disguised confinement. Throughout his life, but particularly in the later part of it, he was subject to prolonged fits of melancholia, during which he would not even speak. He died of apoplexy on the 9th of July 1746. The best account of Philip's character and reign is still that given by Coke in his "Memoirs of the Kings of Spain of the House of Bourbon" (London, 1815).

PHILIP THE BOLD (1342-1404), duke of Burgundy, fourth son of John II. of France and Bonne of Luxemburg, was born on the 15th of January 1342. He earned his surname by his bravery while fighting by his father's side on the field of Poitiers. After the defeat of King John he accompanied him into captivity in England. In 1360 he received the title of duke of Touraine, and in June 1363 was entrusted with the government of Burgundy, which John had united to the crown at the death of the last duke of the Capetian family, Philip of Rouvre, in 1361. In September 1363 John bestowed on Philip the title of duke of Burgundy, together with that of first peer of France. John was anxious not to displease the Burgundians, who were accustomed to their independence; and, moreover, with Philip as duke of Burgundy he was in a better posture to resist the king of Navarre, Charles the Bad, who laid claim to the duchy. The donation, which was at first kept secret in spite of a request made in 1363 for its confirmation by the emperor Charles IV., was ratified at the accession of Charles V. of France; but in consequence of Philip's preoccupation with the Grand Companies, which had invaded France, it was not until November 1364 that he definitely took possession of the duchy. Charles continued to show favour to his brother, appointing him (in 1366) his lieutenant in Champagne and marrying him to Margaret, daughter and heiress of Louis of Mâle, count of Flanders, and widow of Philip of Rouvre. Edward III. of England was negotiating for the marriage of this princess with his son Edmund, earl of Cambridge; but Charles prevailed upon Pope Urban V. to refuse the dispensation necessary on grounds of kinship, and even consented to give up Lille, Douai and Orchies to Flanders on condition that Margaret should marry his brother. Philip eventually won the day, thanks to the support of the late count's mother, and the marriage took place with high revel at Ghent on the 19th of June 1366.

During the succeeding years Philip proved a faithful ally to Charles. He took part in the almost bloodless campaign against the duke of Lancaster, who had landed at Calais; in 1377 he took several towns in French Flanders from the English; and in 1379 relieved Troyes, which had been besieged by the English. On Charles's death Philip found himself, with his brothers, the dukes of Anjou and Berry, in charge of the government of France in the name of Charles VI., who was a minor; and in the absence of the duke of Anjou, who left France in 1382 to conquer the kingdom of Naples, Philip occupied the most powerful position in the realm. He persuaded the young king to intervene in Flanders, where the citizens of Ghent, whose rebellious spirit had necessitated Philip's intervention in 1379, had again revolted under Philip van Artevelde and had expelled Louis of Mâle. On the 27th of November 1382 the Franco-Burgundian chivalry crushed the rebels at Rosebecke, and on his return the dukes of Burgundy took part in repressing the popular movements which had broken out in Paris and other French towns. In 1383 an insurrection in Flanders supported by England gave rise to another French expedition; but in January 1384 the death of Louis of Mâle made Philip master of the countships of Flanders, Artois, Rethel and Nevers; and in the following year the citizens of Ghent decided to submit. At this period Philip sought to ingratiate himself with the emperor, who was a near neighbour, and of whom he had a part of his dominions, by giving two of his daughters in marriage to two princes of the house of Bavaria; he also took an important part in bringing about the marriage of a princess of the same family, Isabel, to King Charles VI.

Hostilities, however, were renewed between France and England. A formidable expedition was prepared under the direction of the duke of Burgundy, and a fleet of 1400 sail assembled at Sluys; but the enterprise failed owing to the dilatoriness of the duke of Berry. The fatiguing and inglorious expedition in the Netherlands, into which the duke dragged Charles for the purpose of supporting his kinswoman, Joan of Brabant, against the claims of John the Stain of the Valois, sealed Philip's credit with his nephew, who on his return declared himself against and confided the government to the ancient councillors of his father, the "Marmousets." The king's madness (1392) restored his uncle's power, and particularly Philip, who after assuring peace by treating with the duke of Brittany and by concluding a truce of twenty-eight years with England, made strenuous efforts to put an end to the Great Schism, visiting Pope Benedict XIII.
at Avignon in 1395 in the hope of obtaining a voluntary resignation from him. The growing influence of the king's brother, Louis of Orleans, who was the focus of great intimacy with Queen Isabel and was accused of being a Freemason, was a serious obstruction. Discord broke out in the council, and for the intervention of the dauphin of Berry and Bourbon the two princes would have come to an open struggle. For a brief period Philip was dispossessed of authority, but he regained it in 1402 and kept it till his death, which took place on the 27th of April 1404. The cathedral of St Bénigne at Dijon contains his remains, and his tomb (formerly in the Chartreuse of Dijon) is now in the museum in the Hôtel-de-ville.

Moreover, Liege 1430 obtaining his redemption of dudgeon, Philip appears to have governed his territories with sagacity and a certain moderation, and he was particularly successful in employing the resources of France in the interests of Burgundy. He granted numerous privileges to the inhabitants of Dijon, and created in 1386 two chambres des comptes, one at Dijon and the other at Lille. He was, in the phrase of a contemporary, "kindly and amiable to high and low and those of middle rank, liberal as an Alexander, noble and pontifical, in court and state magnificent." But his liberality and his love of display involved him in enormous expense, and he left so many debts that his widow was compelled to renounce her personal estate to avoid the responsibility of discharging them. By his wife Margaret (d. 1405) he had a numerous family: John the Fearless, who succeeded him; Charles and Louis, who both died in infancy; Anthony, count of Rethel, and Philip, count of Nevers, both killed at Agincourt; Margaret, who married William of Bavaria, count of Ostrevant; Catherine, wife of Leopold, duke of Austria; Mary, wife of Amadeus VIII of Savoy; and Bonne, who was betrothed to John of Bourbon and died young.

(R. Fo.)

PHILIP THE GOOD (1396-1467), duke of Burgundy, son of John the Fearless, duke of Burgundy and Margaret, daughter of Braband, was born at Dijon on the 13th of June 1396, and succeeded his father on the 10th of September 1419. The natural outcome of the assassination of John the Fearless (q.v.) was to drive his successor to the English side. In 1419 Philip signed with Henry V. of England the treaty of Arras, by which he recognised Henry as regent and future heir of the kingdom of France, and in 1420 gave his adherence to the treaty of Troyes. Early in December 1420 Philip entered Paris with the king of England, and subsequently took part in the defeat of the French at Mons-en-Vimeur. By a treaty concluded by Philip at Amiens in April 1423 with the dukes of Brittany and Bedford, John, duke of Bedford, married Philip's sister Anne, and Arthur of Brittany, earl of Richmond, became the husband of Philip's sister Margaret. A few years later discord arose among the allies. When the duke of Bedford besieged Orleans the inhabitants offered to surrender, but to the duke of Burgundy; whereupon Bedford retorted that "he did not beat the bushes for others to take the birds." When this speech reached Philip's ears he withdrew his troops in dudgeon, and concluded a truce with France (1429). Bedford, however, succeeded in conciliating him by promises and presents, and in 1430 Philip took part in the campaign against Compiègne.

But another conflict arose between the duke of Burgundy and the English. Jacqueline, countess of Hainaut, the divorced wife of the duke of Brabant and the heiress of Holland and Zeeland, had married the duke of Gloucester, who attempted to take forcible possession of his wife's territories. Philip, however, himself claimed Brabant as having been bequeathed to him by his cousin Philip, the late duke, with the result that the Burgundians repulsed the troops of the duke of Gloucester, and Jacqueline was forced to recognize the duke of Burgundy as her lieutenant and heir. Moreover, the duchess of Bedford had died in 1433. Charles VII., who in spite of the efforts of the cardinal of Ste-Croix and the conferences held by him at Auxerre and Semur had hitherto refused to return to France, finally decided to take part in the conferences which were opened at St Vaast d'Arras on the 6th of August 1435, and to throw the whole of Christendom into disorders. In consequence, all the princes of Europe and the pope and the council of Basel being represented. Philip consented to a reconciliation with the king of France, and agreed to recognize him as his legitimate sovereign on condition that he should not be required to pay him homage during his lifetime. Charles, on his part, solemnly vowed a crown for the murder of John the Fearless through the mouth of the dean of the church in Paris, and handed over to the duke the counties of Mâcon, Auxerre, Bar-sur-Seine and Pontchic, and the towns on and near the Somme (Roye, Montdidier, Péronne), reserving the option of further cessions to the king. Philip had meanwhile procured a faithful ally of the king, aiding him in re-entering Paris and preparing an expedition against Calais, which, however, failed through the ill-will of his Flemish subjects (1436). In 1440 he paid the ransom of Charles of Orleans (the son of his father's old enemy), who had been a prisoner in England since the battle of Agincourt; received him with great honour at Gravelines; and married him to Mary of Cleves, upon whom he bestowed a handsome dowry. In 1442 Philip entered into a conspiracy to give the duke of Orleans a larger share in the affairs of the kingdom. To René d'Anjou, the duke of Loraine, he showed himself less generous, setting up another claimant to the duchy of Lorraine in the person of Anthony of Vaudemont, and taking René prisoner in 1431; it was not until 1436 that he consented definitively to release René on condition that he should abandon several strong places and pay an enormous ransom. In 1445, at the conferences of Châlons-sur-Marne, the duchess of Burgundy renounced these claims in her husband's name in order to assure the execution of the treaty of Arras.

Philip was frequently disturbed by the insubordination of the Flemish communes. He had to quell seditions at Liége (1430), Ghent (1432) and Antwerp (1433). In 1438 he was driven with the duchess out of Bruges by the revolted citizens, a revolt which he reppressed with great severity. In 1448 the citizens of Ghent rose in rebellion, but, disappointed of French support, they were defeated at Rupelmonde and in 1453 were overwhelmed at the battle of Gavre, where they left 20,000 dead on the field. At a banquet shortly afterwards Philip vowed that he would lead a crusade against the Turks, who had seized Constantinople, and the knights of his court swore to follow his example. The expedition, however, did not take place, and was but a pretext for levying subsidies and for knightly entertainments. In 1459 Philip sent an embassy under the duke of Cleves into Italy to take part in the conferences preparatory to a fresh expedition against the Turks, but this enterprise likewise fell to the ground. In 1456 the duke of Burgundy had given an asylum to the Dauphin Louis (afterwards Louis XI.), who had quarrelled with his father and had been forced to leave France. The "fox who would rob his host's hen-roost," as the old king called Louis, repaid his protector by attempting to sow discord in the ducal family of Burgundy, and then retired to the castle of Genappe in Brabant. At Charles VII.'s death, however, Philip was one of the first to recognize the new king, and accompanied him to Paris. During the journey Louis won over the seigneurs of Croy, the principal counsellors of the duke of Burgundy, and persuaded Philip to allow him to redeem the Somme towns for the sum stipulated in the treaty of Arras. This proceeding infuriated Philip's son Charles, count of Charolais, who prevailed upon his father to break his pledge and declare war on the king of France. On the 12th of April 1465 Philip handed over to his son the entire administration of his

1 This was the singular vow known as "the vow of the phaenost," from the fact that Philip placed his hand solemnly on a phaenost, which had been brought to him by his herald, and vowed that he would fight the Turks and challenge their sultan to single combat.
estates. The old duke died at Bruges on the 15th of June 1497, and was buried at Dijon.

Philip was a great lover of pomp and luxury and a friend of letters, being the patron of Georges Chastelain, Olivier de la Marche and Antoine de la Salle, and the founder of the collection of MSS. known as the "Bibliothèque de Bourgogne" (now at Brussels), and also of the university of Dôle (1421).

He administered his estates wisely; promoted commerce and industry, particularly in Flanders; and left his son a well-lined treasury. He was thrice married: in 1409 to Michelle (d. 1422), daughter of Charles VI, of France; in 1424 to Bonne of Artois (d. 1425); and in 1429 to Isabel (d. 1472), daughter of John I, king of Portugal. On the occasion of his third marriage Philip founded the order of the Golden Fleece. He was succeeded by Charles, afterwards known as Charles the Bold, his only surviving son by Isabel. He had several illegitimate children, among them being Cornelle, called the Grand Bastard, who was killed in 1452 at the battle of Rupelmonde.

(R. P. O.)

PHILIP, LANDGRAVE OF HESSE (1504-1567), son of the landgrave William II, was born at Marburg on the 15th of November 1504. He became landgrave on his father's death in 1509, and having been declared of age in 1518, was married in 1523 to Christina, daughter of George, duke of Saxony (d. 1530). In 1522 and 1523 he assisted to quell the rising of Franz von Sickingen (q.v.), who had raided Hesse five years previously, and in 1525 he took a leading part in crushing the rebellion of the peasants in north Germany, being mainly responsible for their defeat at Frankenthal. About this time Philip adopted the reformed faith, of which he was afterwards the zealous and daring defender. Indifferent to theological, or even to patriotic, considerations, his plans to protect the reformers rested upon two main principles—unity among the Protestants at home and military aid from abroad. The schemes he put forward as one of the heads of the league of Schmalkalden, aimed primarily at overthrowing the house of Habsburg; to this end aid was sought from foreigner and native, from Protestant and Catholic alike. Envoy was sent repeatedly to France, England and Denmark; Turkey and Venice were looked to for assistance; the jealousy felt towards the Habsburgs by the Bavarian Wittelsbachs was skillfully fomented; and Roman Catholics amongst the revolutionists assured that attack was the best, nay the only, means of defence. Before the formation of the league of Schmalkalden Philip was very intimate with Zwingli, and up to the time of the reformer's death, in 1531, he hoped that material aid would be forthcoming from his followers. In 1526 he had aided John the Constant, elector of Saxony, to form an alliance of reforming princes; and in 1529 he called together the abortive conference at Marburg, hoping thus to close the breach between Lutherans and Zwinglians. More aggressive was his action in 1528. Deceived by the forgeries of Otto von Pack (q.v.), he believed in the existence of a conspiracy to crush the reformers, and was only restrained from attacking his enemies by the influence of John of Saxony and Luther. He succeeded, however, in compelling the archbishop of Mainz and the bishops of Würzburg and Bamberg to contribute to the cost of his mobilization. Philip was freely accused of having employed Pack to concoct the forgery; and, although this charge is doubtful, false, his eager acceptance of Pack's untrue statements aroused considerable ill-feeling among the Catholics, which he was not slow to return. In 1529 the landgrave signed the "protest" which was presented to the diet at Spires, being thus one of the original "Protestants." In 1530 he was among the subscribers to the confession of Augsburg; and the formation of the league of Schmalkalden in the same year was largely due to his energy.

His next important undertaking, the restoration of Ulrich, duke of Württemberg (q.v.), to his duchy, was attended with conspicuous success. Württemberg had passed into the possession of the Habsburgs, but after Philip's brief and victorious campaign in 1534 the humiliation of Charles V. and his brother, the German king, Ferdinand I., was so complete that it was said the landgrave had done more for Protestantism by this enterprise than a thousand of Luther's books would do. After this victory Philip entertained the idea of coming to terms with Charles V. on the basis of extensive concessions to the Protestants; but he quickly returned to his former plans for leading a general attack on the Habsburgs. The Concord of Wittenberg, made in 1536, was favourable for these schemes, but after five years spent in assiduous preparation war was prevented by the serious illness of the landgrave and the lukewarmness of his allies. Recovering from his malady, he had returned to his intrigues when an event happened which materially affected the fortunes of the Reformation. His union with Christina was not a happy one, and having fixed his affections upon Margaret von der Saal (d. 1560), he obtained an opinion from Protestant theologians that bigamy was not forbidden by Holy Writ. Luther and Melancthon at length consented to the marriage, but stipulated that it should be kept secret, and it was celebrated in March 1546. The marriage, however, became known, and a great outcry arose against Philip, whose friends quickly deserted him. He objected to Luther's counsel to deny the existence of a second marriage; abused John Frederick, elector of Saxony, for not coming to support him; and caused bigamy to be publicly defended. Alarmed, however, by the strength of his enemies, and by their evident determination to punish him as a bigamist, he in June 1541 made a treaty with Charles V. at Regensburg. In return for a general pardon he undertook to break off relations with France and England and loyally to support the emperor.

During these years Philip had been forwarding the progress of the Reformation in Hesse. This was begun about 1526, when an important synod was held at Homburg; the university of Marburg was founded in the interests of the reformers in 1527; and after the diet of Spires in 1529 the work was conducted with renewed vigour. The Catholic worship was suppressed, and the secularized church revenues supplied an endowment of the new university.

The peace between the emperor and the landgrave was soon broken. In 1542 Philip persuaded the league of Schmalkalden to attack Henry II., duke of Brunswick-Wolfenbüttel, ostensibly in the interests of the Protestant towns of Brunswick and Goslar. The duchy was quickly overrun, and Henry—a Catholic prince—was put to death, but the good understanding between the emperor and the landgrave was destroyed, and the relations between Protestants and Catholics became worse than before. Nor was the fissure in the Protestant ranks closed, and Charles took advantage of this disunion to conquer Gelderland and to mature his preparations for overthrowing the league of Schmalkalden. Unlike John Frederick of Saxony, Philip divined, or partly divined, the emperor's intentions, and urged repeatedly that the forces of the league should be put in order. This advice passed unheeded, and when Charles suddenly showed his hand, and in July 1546 issued the imperial ban against the landgrave and the elector, it was seen that the two princes were almost isolated. Philip was busied along the upper Danube, and when indecision and want of funds had ruined the league's chances of success, Philip returned to Hesse and busied himself with seeking help from foreign powers; while in April 1547 John Frederick was captured at Mühlberg. After this defeat the landgrave was induced to surrender to Charles in June by his son-in-law, Maurice, now elector of Saxony, and Joachim II., elector of Brandenburg, who promised Philip that he should be pardoned, and were greatly incensed when the emperor refused to assent to this condition. There is, however, no truth in the story that the word ewiges, rendered by an imperial servant into ewiges, thus making the phrase "without any imprisonment," in the original sentence to read "without any perpetual imprisonment." Philip was sentenced to detention for fifteen years, and as he was heartily disliked by Charles his imprisonment was a rigorous one, and became still more so after he had made an attempt to escape. His acceptance of the Interim in 1548 did not bring him freedom; but this came in consequence of the humiliation of
Charles V. at the hands of Maurice in 1552; and after the conclusion of the peace of Passau in this year he returned to Hesse. Although less active than formerly, the landgrave did not cease to intrigue on behalf of the Protestants while continuing the work of reformating and organizing the Church in Hesse. In 1562 he aided the Huguenots with troops, and he was frequently in communication with the insurgents in the Netherlands; but his efforts to form a union of the Protestants were fruitless. Philip, who had since nominally called the Magnaten, died at Calw on 31st of March 1567. By Christina he had four sons and five daughters, and according to his directions the landgraviate was partitioned at his death between his sons. He had also by Margaret von der Saal seven sons, who were called counts of Dietz, and one daughter.

PHILIP, JOHN (1775–1851). British missionary in South Africa, was born on the 14th of April 1775, at Kirkcaldy, Fife, the son of a schoolmaster in that town. After having been apprenticed to a linendraper, and for three years a clerk in a Dundee business house, he entered the Hoxton (Congregational) Theological College, and in 1804 was appointed to a Congregational chapel in Aberdeen. In 1818 he joined the Rev. John Campbell in his second journey to South Africa to inspect the stations of the London Missionary Society, and reported that the conduct of the Cape Colonists towards the natives was deserving of strong reprobation. In 1822 the London Missionary Society appointed him superintendent of their South African stations. He made his headquarters at Cape Town, where he also established and undertook the printing of the Bible. In June 1828 he was arrested by the barbarities inflicted upon the Hottentots and Kaffirs (by a minority of the colonists), and he set himself to remedy their grievances; but his zeal was greater than his knowledge. He misjudged the character both of the colonists and of the natives, his cardinal mistake being in regarding the African as little removed from the European in intellect and capacity. It was the period of the agitation for the abolition of slavery in England, where Philip’s charges against the colonists and the colonial government found powerful support. His influence was seen in the ordinance of 1828 granting all free coloured persons at the Cape every right to which any other British subjects were entitled. But in 1826–1828 he was in England, and in the last-named year he published Researches in South Africa, containing his views on the native question. His recommendations were adopted by the House of Commons, but his unpopularity in South Africa was great, and in 1830 he was convicted of libelling a Cape official. The British government, however, caused the Cape government to conform to the views of Philip, who for over twenty years exercised a powerful, and in many respects unfavourable, influence over the destinies of the country. One of Philip’s ideals was the curing of colonial "aggression" by the creation of a belt of native states around Cape Colony. In Sir Benjamin D’Urban Philip found a governor anxious to promote the interests of the natives at Grossmäthigen (Cassel, 1900); when the close of the Kaffir War of 1834–35 D’Urban annexed the country up to the Kei River, Philip’s hostility was aroused. He came to England in 1836, in company with a Kaffir convert and a Hottentot convert, and aroused public opinion against the Cape government. His views triumphed, D’Urban was dismissed, and Philip returned to the Cape as unofficial adviser to the government on all matters affecting the natives. For a time his plan of buffer states was carried out, but in 1836 another Kaffir rising convinced him of the futility of his schemes. The Kaffir chief who had accompanied him to England joined the enemy; and many of his converts showed that his efforts on their behalf had effected no change in their character. This was a blow from which he did not recover. The annexation of the Orange River Sovereignty in 1848 followed, finally destroying his hope of maintaining independent native states. In 1849 he severed his connexion with politics and retired to the mission station at Hankey, Cape Colony, where he died on the 27th of August 1851.

PHILIP, KING (c. 1635–1676), chief sachem of the Wampanoag Indians in America, and the son of Massasoit (d. 1662) as the English, mistaking this title (great chief) for a proper name, called Wooseamequin (Yellow Feather) — who for forty years was the friend and ally of the English colonists at Plymouth. To Massasoit’s two sons, Wamsutta and Metacomet, the English gave the names respectively of Alexander and Philip. Alexander succeeded his father as sachem, and in the same year, while in Marshfield, whither he had gone to explain certain alleged unfriendly acts toward the English, was taken ill; he died on his way home. Philip, who succeeded Alexander, suspected the English of poisoning his brother. The English had grown stronger and more numerous, and had begun to meddle in the internal affairs of the Indians. In 1667 one of Philip’s Indians accused him to the English of attempting to betray them to the French or Dutch, but this charge was not proved. In 1671 the Plymouth authorities demanded that the Wampanoags should surrender their arms; Philip consented, but his followers failed to comply, and measures were taken to enforce the promise. Philip thereupon went before the general court, agreed to pay an annual tribute, and not to sell lands or engage in war with other Indians without the consent of the Plymouth government. In 1674, when three Wampanoags were executed at Plymouth for the alleged murder of Sassamon, an Indian convert who had played the part of informer to the English, Philip could no longer hold his followers in check. There were outbreaks in the middle of the island when the whites began. There was no concerted movement of the various tribes and the war had not been previously planned. The Nipmuck Indians rose in July; the tribes along the Connecticut river in August; those in the present states of Maine and New Hampshire in September and October, and the Narragansets in December, when (on the 19th) they were attacked and seriously crippled, in what is now the township of South Kingstown, Rhode Island, by the English (under Governor Josiah Winslow of Plymouth), who suspected their loyalty.

The colony of Connecticut took quick measures of defence, guarded its frontier, maintained its alliance with the Mohicans, and suffered little injury. Massasoit and Plymouth were slower in acting and suffered great loss. Rhode Island raised no troops, and suffered severely. Early in the autumn Philip went nearly as far west as Albany in an unsuccessful attempt to get aid from the French and the Mohawks and supplies from the Dutch traders. At Deerfield on the 18th of September about 60 English were killed and the settlement was abandoned. In the spring of 1676 it became evident that the Indian power was waning. The warriors had been unable to plant their crops; they were weaker numerically and more poorly armed than the English, and the latter had also made an alliance with the friendly Naticks and the Niantics. On the 1st of August 1676 Philip’s wife and nine-year old son were captured, and on the 11th of August an Indian trader came to the English, and the sachem’s hiding place in a swamp at the foot of Mount Hope (in what is now the township of Bristol, Rhode Island), where early the next morning he was surprised, and while trying to escape was killed by an Indian. The head of Philip was sent to Plymouth and set...
PHILIPPA OF HAINAUT—PHILIPPIANS

on a pole in a public place, where it remained for a quarter of a century; his right hand was given to his slayer, who preserved it in rum and won many pennies by exhibiting it in the New England towns. The struggle was now carried in support of New England, but it continued along the north-eastern frontier till the spring of 1678, and nearly every settlement beyond the Piscataqua was destroyed. In the colonies of Plymouth, Massachusetts, Rhode Island and Connecticut six hundred men (or about 9% of the fighting population), besides many women and children, had been killed; thirteen settlements had been completely destroyed, and about forty others were partly burned. Plymouth had incurred a debt greater than the value of the personal property of her people. The Indians suffered even worse: in addition to the large number of men, women and children slain, great numbers, among them the wife and son of Philip, were sold into slavery in the Spanish Indies and the Bermudas. Many others migrated from New England to New York; and the few remaining Indians, feeble and dispirited, were no longer a power to be reckoned with. Philip was an Indian patriot and statesman, not a warrior; he united the tribes in their resistance to the colonists, but was not a great leader in battle.

See George M. Bodges, Soldiers in King Philip’s War (Lexington, Mass., 1896); John Gorham Palfrey, History of New England, vol. iii. (Boston, 1864); and especially George W. Ellis and John Saccarappa, Entertaining Passages Relating to King Philip’s War (Boston, 1871; new edition, edited with notes by H. M. Dexter, Boston, 1898), the account by Colonel Benjamin Church (1659-1718), of the principal leaders of the English, of the warfare in southeastern New England, in which he took part; it is one of the most famous and realistic accounts of early Indian warfare.

PHILIPPA OF HAINAUT (c. 1314-1369), queen of the English king Edward III., was the daughter of William the Good, count of Holland and Hainaut, and his wife Jeanne de Valois, granddaughter of Philip III. of France. Edward visited the court of Count William in 1326 with his mother Isabella, who immediately arranged a marriage between him and Philippa. After a dispensation had been obtained for the marriage of the cousins (they were both descendants of Philip III.) Philippa was married by proxy at Valenciennes in October 1327, and landed in England in December. She joined Edward at York, where she was married on the 30th of January 1328. Her marriage dowry had been seized by the queen dowager Isabella to pay a debt of Hainauters, with whose help she had compassed her husband’s deposition. The alliance ensured for Edward in his French wars the support of Philippa’s influential kindred; and before starting on his French campaign he secured troops from William the Good, as well as from the count of Gelderland, the count of Julich, and the emperor Louis the Bavarian. Her mother Jeanne de Valois, visited her in 1331 and further cemented the community of interests between England and Flanders. Before 1335 Philippa had established a small colony of Flemish weavers at Norwich, and she showed an active interest in the weaving trade by repeated visits to the town. She also encouraged coal-mining on her estates in Tynedale. Her eldest son, Edward the Black Prince, was born in 1330, and she subsequently bore six sons and five daughters. In November 1342 she became guardian of John of Gaunt and her younger children, with their lands. Her agents are said to have shown great harshness in collecting the feudal dues with which to supply her large household. The anecdotes of her piety and generosity which have been preserved are proof, however, of her popularity. She interceded in 1331 with the king for some carpenters whose careless work on a platform resulted in an accident to her son and her ladies, and on a more famous occasion her prayers saved the citizens of Calais from Edward’s vengeance. There is a generally accepted story, based on the chronicles of Jehan le Bel and Froissart, that she summoned the English forces to meet the Scottish invasion of 1346, and harangued the troops before the battle of Neville’s Cross. She certainly exercised considerable influence over her husband, whom she constantly accompanied on his campaigns; and her death on the 15th of August 1369 was a misfortune for the kingdom at large, since Edward from that time came under the domination of the rapacious Alice Perrers. Philippa was the patron and friend of Froissart, who was her secretary from 1361 to 1366. Queen Elizabeth, Oxford, was named as is stated in Skelton’s version of her epitaph, founded by her, but by her chaplain, Robert of Eglesfield. Her chief benefactions were made to the hospital of St Katharine’s by the Tower, London.

See Agnes Strickland, Lives of the Queens of England, vol. i. In addition to the account given in his Chroniques, Froissart wrote a formal eulogy of her, which has been lost.

PHILIPPEVILLE, a seaport of Algeria, chief town of an arrondissement in the department of Constantine, and 54 m. N. by E. of that city, on the Bay of Stora, in 36° 53’ N. 6° 54’ E. It is connected by railway with Constantine, Batna and Biskra. The town derives its importance from being the port of Constantine. The harbour works, with every vessel in port, having been destroyed by a storm in 1878, a more commodious harbour was built, at a cost of about £1,200,000. From Cape Skikda, on the east a mole or breakwater projects 450 ft. to the W.N.W., while from Château Vert on the west another mole runs out 1312 ft. to the north, leaving an entrance to the port about 650 ft. wide. The protected area comprises an outer and an inner basin. The depth of water at the entrance is about 33 ft., alongside the quays about 20 ft. The quays are faced with blocks of white marble brought from the quarries at Fililia, 16 m. distant. Pop. (1906), of the town 16,539, of the commune 26,950, of the arrondissement, which includes 12 communes, 147,607.

Philippeville occupies the site of successive Phoenician and Roman cities. By the Romans, under whom it attained a high state of prosperity, it was named Ruscida. In the middle ages the town ceased to be inhabited. The site was purchased from the Arabs by Marshal Valére in 1838 for £6. Some parts of the Roman theatre remain, but the stones of the amphitheatre, which stood without the walls of the modern town, and which the French found in an almost perfect state of preservation, were used by them for building purposes, and the railway was cut through the site. On a hill above the town are the Roman reservoirs, which have been restored and still supply the town with water. They are fed by a canal from the Wadi Beni Melah. The Roman baths, in the centre of the modern town, serve as cellars for military stores.

PHILIPPI (Turk. Filibejik), a city of ancient Macedonia, on a steep hill near the river Gangites (mod. Avgista), overlooking an extensive plain and at no great distance from the coast of the Aegean, on the highway between Neapolis (Kavalla) and Thessalonica. Originally called Crenides (Fountains), it took its later name from Philip II. of Macedon, who made himself master of the neighbouring gold mines of the Hill of Dionysus, and fortified the city as one of his frontier-towns. In 42 B.C., after the victory gained over the senatorial party by Octavius and Antony, it became a Roman colony, Colonia Julia Philippensis, which was probably increased after the battle of Actium (Col. Avg. Julia Phil.), the inhabitants received the Jus Italicum, and Philippus was one of the specially designated “first cities” (Acts xvi. 12; see Marquardt, Röm. Staatsverwaltung, i. 187). The city was twice visited by St Paul, whose Epistle to the Philippians was addressed to his converts here. The site, now uninhabited, is marked by ruins—the substructions of an amphitheatre, parts of a great temple—which have furnished interesting inscriptions. A little to the east is the huge stone monument of C. Vilius, known to the Turks as Dikeiltashlar and to the Greeks as the Manger of Buchephas.

See Heuzey and Daumat, Mission arch. en Macédoine, Paris (1865), and other authorities in bibliography of Macedonie; Corp. Inscriptionum Lat. iii. 1.

(PHILIPPIANS, EPISTLE TO THE, a book of the New Testament. Communications had already passed between the Christians of Philippia and Paul, not only when he was at Thessalonica (iv. 15-16), but at some subsequent period (iv. 18), when Eppharoditus had brought him a present of money from them. It is possible that this gift was accompanied by a letter. At any rate the extant epistle is the answer to one received from the Philippian Christians, who had evidently desired information about the
aphate's health and prospects (i. 12), assured them of his prayers (i. 19), and wondered whether he, their pride and glory (καίγομαι), would return to them (i. 25 seq.).

After a brief greeting (i. 1, 2), Paul assures them of his loving interest in their present attainments and future progress in the faith of the gospel (i. 3-11); then, relieving their anxiety about his own prospects, he expresses the confident hope that he will be released and thus able to return to them (ii. 12-26). Meantime they were to avoid any pride or factiousness which might break their unity as a church (i. 27-ii. 18), and they are promised a visit from two of Paul's coadjutors, who are well known to them (ii. 19-30). At this point the letter suddenly swerves into a passionate warning against some errors of Judaisers (iii. 1-iv. 1), after which the appeal to Christianity at Philippi is conducted (iv. 2-9), and the epistle closes with some personal details (iv. 10-23).

Paul is a prisoner when he writes, and the place of composition may therefore be Caesarea or Rome (Acts xxviii. 16, 30-31). The evidence upon the whole seems to point to the latter. The phrase οἴκα Καλαροσ (iv. 22) suits Rome better than Caesarea, and, while πρωτάρων (i. 13) does not necessarily imply the capital, it is most naturally understood of Rome. But the whole tone of the epistle suggests that Paul expected a speedy end to his case. Now at Caesarea this was out of the question. His appeal to Caesar involved a protracted process, and it is very improbable that the Philippian epistle was written during those e.g. of ii. 23 into such a situation. The critical outlook of Philippians does not correspond with the position of the apostle at Caesarea, nor can the latter town be said to have been a centre of vigorous Christian propaganda (i. 17). Finally, the contention that no visit of Timothy to Rome is known is an argument from silence which is of little more weight than the plea of Spitta that the cupidity of Felix (Acts xxiv. 26) was excited by the arrival of the money from Philippi (Phil. iv. 16).

A further examination of the epistle shows that it must have been written towards the close of the ἐβδοματία of Acts xxviii. 30, not in the earlier part of the Roman captivity. Paul is on the point of starting on his third mission (Acts xxvii. 23), and his epistle shows that he did pass a period during which considerable progress has been made in the local preaching and extension of the gospel, nor does the language of the apostle suggest that this fresh departure in the propaganda was stimulated by the mere novelty of his arrival. Furthermore, the relations between the Philippians and himself presuppose, on any fair estimate, an interval of time which cannot be crushed into a few months. News of his arrival must have reached them; money was collected (ii. 25, iv. 18) and then forwarded by Epaphroditus, who fell sick after he reached the capital; news of this again floated back to Philippi, and subsequently Paul heard of the Philippians' concern (ii. 26). Not till then this letter was written.

Philippians is thus the last extant letter we possess from Paul, unless some of the notes embedded in the pastoral epistles are to be dated subsequent to its composition. It unites the close of his career in Rome with the beginning of his mission work in Europe (iv. 15; cf. Acts xvi. 12), and illustrates not merely the situation of the apostle at Rome, but the terms of exceptional affecfion which existed from first to last between him and the Macedonian churches. The main argument for putting it earlier is derived from the admitted affinities between it and Romans, the Colossian and Ephesian epistles containing, it is held, a more advanced christiology (so Lightfoot especially, and Hort, Judaistic Christianity, pp. 115-139). But such considerations are not decisive. Paul wrote from time to time, not in the execution of a literary plan, but as different objects or interests called out his powers. The Philippians did not require, and therefore did not receive, the same elaborate warnings as the Asiatic churches. Hence on the one hand it is unreal to lay stress on coincidences with Romans, and on the other it is necessary to concede that both epistles must have been composed shortly after one another, whether we give the further stage of thought on Christ and the Church, which is evident in Colossians, does not prove that the latter must have followed the former. Upon the whole, the internal evidence of the epistle strongly favours its position as the last of the captivity epistles.

The attempts made during the 19th century to disprove the Pauline authorship now possess merely an historic interest, nor have the various hypotheses of more or less extensive interpolation won any serious support. More significance attaches to the view that the epistle is made up of two separate notes, one, dated 27 A.D. ii. 1-7, and the other intermediate (ii. 8-26). The fusion of the two is found in the abrupt hiatus of iii. 1, and evidence is led from supposed inconsistencies between the earlier and the latter parts of the epistle. But the flexibility of a letter-writer, under different moods of feeling, which would naturally lead to rapid transitions, may be adduced as some explanation of the latter phenomena. The exegesis does not absolutely necessitate a partition of the epistle, which (so Heinrichs and Paulus) would make iii. 1-iv. 20 a special letter addressed to some inner circle of the apostle's friends (in spite of iv. 16 seq.), or take iii.-iv. (Hausrath, History of N. T. Times, iv. 162 seq. and Bacon, Story of St Paul, pp. 306 seq.) as earlier than i.-ii. Besides, as Pelicer points out, the two halves of the epistle are balanced: "each of the epistles had but one essential part: the first, in particular, lacking an expression of thanks for the gift from the Philippians, which must nevertheless, according to ii. 25, have already taken place." In his letter to the Philippians (iii. 2) Polycarp indeed observes that Paul wrote ἐπιστολάς to them; but, even if the plural could not be taken as equivalent to a single dispatch, it would not necessarily support the partition theory of the canonical Philippians. Polycarp may have known of more than one Pauline note to Philippi, no longer extant, or he may be referring loosely to 2 Thessalonians, which was addressed to the Macedonian churches. The exegetical arguments are, in short, the final court of appeal, and their verdict tells rather in favour of the epistle's integrity. The simplest account of iii. 1 is to suppose that Paul started afresh to complete or supplement what he had already written, possibly because some fresh tidings from Philippi had reached him in the interval. Psychologically the change from iii. 19 seq., with its note of farewell, to the impassioned outburst of iii. 2 seq., is not incredible in an informal letter from a man like Paul. The hiatus is striking, but it cannot be held to necessitate an editorial dovetailing of two separate epistles. It is doubtful, therefore, if the ingenious attempts to analyse Philippians have proved much more consistent than the similar movement of literary criticism upon the first Philippi of Demosthenes, where researches swung back in the main to a conservative position (cf. A. Baroin in Wiener Studien, 1884, 173-205).

The first clear echoes of the epistle are heard in Polycarp, though it was probably known to Clement of Rome and Ignatius (cf. the evidence tabulated in The New Testament in the Apostolic Age). To the details furnished in the present writer's Historical New Testament (2nd ed., 1901, pp. 634-635) may be added references to Völter's Paulus ii, seine Briefe (1905), pp. 286-333, Beller's Einleitung in der N. T. (2nd ed., 1905), pp. 555 seq., and Schmiedel's paragraphs in Ency. Bib. (3147-3148). Pellicer (Primitive Christianity, i. 254 seq.) now hesitates on ii. 6 seq., following Frhr. Like Brückner and Schmiedel. The objections to Paul's authorship on the score of style and grammar are finally set aside by the philological Nägeli in Der Wortschatz des Apostol Paulus 1905), pp. 80-82.
PHILIPPICSA—PHILIPPINE ISLANDS

PHILIPPICS, or the Philippics, an archive belonging to the United States of America, situated about 300 m. off the S.E. coast of Asia between 4° 40' and 12° 30' N. latitude, between 116° 40' and 126° 34' E. It is bounded W. and N. by the China Sea, E. by the Pacific Ocean, and S. by the Celebes Sea and the coastal waters of Borneo. Of the large islands, Luzon (49,009 sq. m.) is the most northerly, and Mindanao (36,292 sq. m.), the most southerly. Between Luzon and Mindanao are Samar (5321 sq. m.), Negros (4881 sq. m.), Panay (4691 sq. m.), Mindoro (3851 sq. m.), Leyte (2722 sq. m.), Cebu (1762 sq. m.), Bohol (1441 sq. m.) and Masbate (1256 sq. m.). Further west and separated from the southern portion of this chain is the long narrow island of Palawan or Paragua (4027 sq. m.). The total land area of the Philippine Islands is 31,592 sq. m., and 92% of this is included in the eleven islands already named. The remaining twenty others, which have an area ranging from 106 sq. m. to 682 sq. m., and the total number of islands enumerated within the archipelago is 3114; of these 2775 contain less than 1 sq. m. each.

**Physical Features.**—The islands are mainly of volcanic origin, and their surface is much broken by hills, isolated volcanoes and mountain ranges, but the country is generally level. Two main chains extend from the east, or north-east and south-west. Extending for 350 m. along the east coast of central and northern Luzon is the Sierra Madre range, a series of summits and peaks to more than 4500 ft. and seldom less than 3500 ft. On the west coast of Luzon and the large island of Mindanao are the Cordilleras, the south-western extends north from the Gulf of Lingayen and the Zambales southward from that gulf to Manila Bay. The Caraballo Occidentales range is very narrow; the central ridge rises a few feet above the valley floor, but it rises in Mt. Datat to 7364 ft., and numerous lesser ranges rise from it. Much of the Zambales range has an average height of 4000 ft. or more, and several peaks are more than 5000 ft. high. Between the Sierra Madre and Caraballo Occidentales is the valley of the Cagayan river, about 50 m. wide, and east of the Zambales range is a lowland basin, about 150 m. long and 50 m. wide, and not more than 100 ft. above the sea except near its centre, where the Cagayan river enters. The valley rises to 2500 ft. and the great portion of southern Luzon is occupied by isolated volcanoes and irregular masses of hills and mountains. Mt. Mayon (7916 ft.), near the south-eastern extremity, is an active volcano with an almost perfect cone, the height of which is 4540 ft. and the diameter of the base 400 ft. Mt. Isarog (6834 ft.) and Mt. Masaraga (5244 ft.) are the prominent volcanoes of the Malayan group. The island of Mindanao is traversed north to south by mountain ranges, which rise in their summits to heights exceeding 4000 ft. That along the east coast is longest and least broken, and between it and the next range inland is the level valley of the Agusan river, from 40 to 50 m. wide. Further west and south-west is the valley of the Rio Grande de Mindanao, the largest on the island, and between the lower course of this river and the mountain chain range with a north-west and south-east trend. On the east border of the southern portion of the basin of the Rio Grande Mindanao is Mt. Togod (3372 ft.), an extinct volcano and the highest elevation in the archipelago.

Each of the larger islands between Luzon and Mindanao, except Samar and Bohol, is traversed longitudinally by a single mountain range with occasional spurs. In Leyte there are three isolated volcanic cones, two of which, in the north part, exceed 4000 ft. In Mindoro the range is broad, extending from coast to coast, and it culminates in Mt. Halcón (about 8800 ft.). In Negros is Mt. Canlón (8192 ft.), a volcano, and several summits exceeding 6000 ft. In Panay is Mt. Madiáas (7264 ft.) and several other peaks exceeding 4000 ft. The highest peaks in Masbate are about 2500 ft. high, and in Cebú not much more than 2000 ft. In Samar there are but few volcanic cones. The scenery in the mountain ranges is very hilly, but the northern portion is more level. Palawan, 275 m. long and about 15 m. wide, is traversed throughout its length by a range of mountains with an average height of 4000 to 5000 ft. and several summits exceeding 6000 ft. These ranges connect not only the islands within the archipelago, but also the archipelago itself with Borneo and Celebes, so that only shallow passes connect the interior waters with the Pacific Ocean and the China Sea. The coast of Palawan in the Palaumbia gulf, in length, is fringed with coral reefs and broken by numerous gulfs and bays.

The Cagayan river, in north Luzon, is the largest in the archipelago. It is about 220 m. long and drains to the northward about 10,000 sq. m., or nearly one-fourth of the island. The Rio Grande de Mindanao (known in its upper course as the Rio Pulangia) drains into the sea in the south-western corner of the central area of Mindanao and is second in size. It and the Agusan, which drains to the northward the mountain valley in east Mindanao, are each about 200 m. in length. The principal rivers of the lowland basins of northern Luzon and the southern part of Mindanao are about 250 m. in length, and discharge through several channels into Manila Bay. The
Agno rises in the mountains on the north border, flows south, south-west and north-west, and discharges through several channels into the Gulf of Lingayen. Each of these has a great number of small tributaries, and along the coast of this lowland basin are many small lakes, e.g. the Minandao. The north of this region is drained by the casually important stream connecting Laguna de Bay with Manila Bay. The Río Bicol, which rises in Lake Bato and flows N.N.W. into the San Miguel Bay, is the principal river of south Luzon. Samar, Panay, Negros and Mindanao are drained by a few great rivers, and few of those in Samar, Panay and Negros are of considerable size.

In the lowland basin of central Luzon, 6 miles inland from Manila Bay, is Laguna de Bay, the largest body of fresh water in the Philippines. A well in the cause of the rest, it is the site of two towns and its coastline, broken on the north by two bays, is distributed as follows: 10 miles long. Lake Taal, a few miles south-west of Laguna de Bay, occupies the crater of a great volcano. It is 177 miles long and 12 miles wide, which, with its associated smaller lakes, forms a large freshwater lake, the island near its centre is the active volcano of Taal, 1050 ft. high.

In north Luzon is Lake Cagayán. In Mindanao there are lakes Las Pailas, Sibuyan, Pulag, and lakes Mainit, Pinaya, Dagon, Sadocum and Limao in the valley of the Agusan. There are small lakes in some of the other islands.

Geology.—The Philippines appear to be the remnants of a somewhat complex system of mountain arcs, which from their similarity in form and direction seem to be in some way connected with the mountain ranges of Annam. The oldest rocks exposed are gneiss, talc-schist and serpentinite, with intrusive masses of gabbro and diorite, dated as very old but possibly not as old as the earth itself; a series of well-preserved geologic deposits of a very late geological period occur near the coast and in the low-lying depressions. Volcanic rocks of modern date cover extensive areas, especially the western part of Luzon and, in Mindanao, the large Lagoons Fractured tuffs are sometimes interbedded with nummulitic limestone, thus showing that the eruptions had already begun in the Eocene period.

Volcanoes and Earthquakes.—There are twelve active volcanoes in the archipelago. They are Babyún Claro, Camiguin de Babuyanes and Didicas in the Babuyanes Islands off the north coast of Luzon; Caguga or Caua in north Luzon; Taal, Mayón and Bulusan in south Luzon; Mactan, Leyte and Leyte, in north Cebú; and the island of Camiguin, off the north coast of Mindanao; and Apo and Calayo in Mindanao. Only a few eruptions have been recorded of any of these, however, except Taal and Mayón, and there has been relatively little danger of eruption since 1754. The eruptions of Mayón in the 19th century, and those of 1814 and 1897 were of great violence. That of 1897 began practically without warning on the 23rd of June, became alarming on the 24th and destructive on the 25th, and ceased on the 30th. Streaks of lava completely destroyed several villages and injured others, as well as the town of San Fernando. The lava flow extended more than 7 miles beyond the town, and ashes were thrown 15 miles and 75 m. to the west. There are eight other volcanoes, which although extinct or dormant have well-preserved cones. They are Aráyát, Bandjao, San Cristobal, Isarog and Malino in south Luzon, and Macahig and Sibdare in Mindanao.

Earthquakes are frequent and occasionally violent. In the seven years 1902-1908 the microseismograph at Manila recorded 790 local earthquakes. In the 47 years ending March 1909 the various regions of the Philippines were visited by about 60 strong earthquakes; 16 of these, in ten different regions, occurred in the decade from 1890 to 1900. There were 8 in the year 1897 alone, and one of these ruined the town of Zamboanga in west Mindanao and caused considerable loss of life by falling buildings and sea waves. A new island appeared at this time off the coast of Borneo near Labuan. The principal centres of disturbance in the valley of the Agusan, in the region of Mayón volcano, in the region of Mactan, and in coastal Masbate and Sibuyan on the north-western shore of Luzon. The islands of Cebú, Bohol, Negros and Palawan are rarely shaken.

Fauna.—The Philippines, politically speaking, and the Philippine zoology, zoologically speaking, are not identical areas. Balabac, Palawan and the Calamianes being characterized by the occurrence of numerous Bornean forms which are conspicuously absent from the other groups, are held to form an eastern extension of the Indo-Malayan sub-region, there is a large amount of specialization in the fauna of the islands eastward of the Palawan group. Mammals are scarce. No mar- supials have been recorded in the northwest or the southeast (Manís sp.) of the Palawan group. In the seas are found the dolphin, cachalot and dugong. Wild hogs of at least two species occur. The beautiful arch deer of Sulu has apparently been brought there, and may now be found from the Sulu archipelago to Leyte, Samar and the Calamianes Islands. The number of species and their respective ranges have not been satisfactorily determined. In Masbate, Panay, Guimaras and Negros there is a dark-coloured species marked with buff spots. Deer are absent in Palawan, Tawi Tawi, Tablas, Romblon, Sibuyan and Siquijor. Humped cattle are raised on most of the islands. They are killed for their flesh, hides and horns and little attention is paid to their milk-giving properties. The water-buffalo, or carabao, occurs in a wild state in Luzon, Mindoro, the Calamianes group, Masbate, Negros and Palawan. Wild horses and tapirs have not originated from domesticated animals. The domesticated water-buffalo is sluggish in its movements, and will not work through the heat of the day; but it is a wonderful swimmer, and makes its journeys through thickets and marshes as though they were used as a draught animal and beast of burden. The most interesting of the ruminants is the timidu (Bubalus mindorensis, Heude), peculiar to Mindoro. Unlike the water-buffalo, it does not bathe in water. Its flesh is extensively consumed, and feeding by night and sleeping by day in the densest jungle. It sometimes charges the hunter without provocation, and is very dangerous when wounded. It attacks and kills the much larger wild buffalo. All attitudinizing movements of the latter is exhibited in Balabac. The house rat, introduced by man, is a common nuisance, and mice occasionally seriously damage sugar-cane and rice crops. Vipers are rare, but the cobras are common. Several species of snakes have been introduced on Marinduque and Mindoro, and on the islands are several species of lizards and iguanas. Some of these, as the chelon, the Burmese python, the Philippine boa, and the macaboo, are amongst the largest reptiles in the world. Several species of scorpions are found in the islands, and of snakes the species of uncertain origin, Echis carinatus, is probably native.

The Islands are rich in birds as they are poor in mammals, the total number of species recorded up to 1906 being 693, of which one-half are peculiar to the Philippines. A study of their geographical distribution has demonstrated that the islands may be divided into four natural groups. The first and smallest group of islands have no birds which are not also found in the Philippines. The birds show a degree of specialization closely correlated with diversity of environment and completeness and probable duration of separation from adjacent groups. Balabac, Palawan and the Calamianes show a very complete separation from the Luzon group by itself. Luzon and the small neighbouring islands have 51 peculiar forms. A close relationship exists between the birds of the entire eastern chain of islands. Numerous genera and some families which are absent from the islands south of Luzon are present from Luzon to Basilan. The genera and species of birds are also distinctly different, and few Formulas of Baldus, which are peculiar to the Philippine islands, are confined to these islands. Several species of birds are restricted to the islands south of Luzon, and again are not confined to the islands south of Luzon. The zoological position of Bohol has not been satisfactorily determined, and the zoological boundary between the central and eastern islands is uncertain. The zoological position of Bohol has not been satisfactorily determined, but all existing evidence indicates that it must be grouped with the central islands. Bohol is peculiar in containing many of the same birds as the islands to the north, but as few of the birds as the islands to the south. Among the most interesting birds may be mentioned the "mountain builder" (Megalopus comingi, Dillwyn), which buries its large eggs in the soft sand along the sea beach, or under great mounds of earth. The eggs are forcibly propelled off the face of the mound by the force of the bird's wings. The eggs are highly prized by the natives. The jungle fowl abounds. There are 35 species of pigeons and doves, many of them most beautifully coloured and all indigenes. Sapi, plover, turnstones and other shore birds are abundant during the winter months.
PHILIPPINE ISLANDS

The cool season, and herons, bitterns and ducks at all times. The birds of prey, 45 species, of which 22 are peculiar to the group, vary in size from a tiny falcon not larger than a sparrow to the immense "hieroglyphic crane" (Grus fasciata, Grant), which is strong enough to seize monkeys as they leap from tree to tree. There are 21 species of kingfishers, 15 being indigenous. Of the 137 types of fish, about 60 are found outside of the Philippines. Frog-moths, bee-birds, night-hawks and swifts are found in considerable variety. One of the last (Collocalia troglodytes, Gray) constructs the edible nests so highly praised by the Chinese. Among the most beautiful water-fowl are the sun-birds, and 23 flower-peckers, tityme, shrikes, swallow-shrikes, tailor-birds, thrushes, fruit-thrushes, fairy blue-birds, fire-birds, 42 fly-catchers, 4 swallows, and 5 species of swifts. Animals with unusual and very large numbers of birds for which English names cannot be readily supplied.

Reptiles and batrachians are abundant, but have been little studied. Pythons occur throughout the group, and sometimes attain enormous size. There are numerous venemous serpents, but the mortality from snake-bite is low. Geckoes may be seen on the walls and ceilings of any house. Flying lizards abound in the inter-tidal zone. The September day is a vacation for them. Their eggs are prized by the natives, and the flesh of one species, known as ibit or pelubid, is highly esteemed. Crocodiles are extremely numerous in many of the streams, and are occasionally found in the sea. Large crocodiles are often obtained measuring 18 ft. in length. Land turtles of small size are common. Very large sea turtles are often captured by the fishermen, and their flesh is highly appreciated as a luxury, and their eggs are much in demand by business ladies. Large black peacock-toucan shell. Frogs occur in great variety. One small species appears in immense numbers with the oncoming of the rainy season, and at night the noise of its outcry almost deadens other sounds.

Fishes are very abundant. About 500 species of food fishes have been found, and common among them are the bangos or milkfish, the banak or mullet, mackerel, herring, anchovies, groupers, snappers, pompano, tarpon and bonito. The largest fish in the Philippines is the wahoo, a paddy-field or tarpon. The shells of the pearl manta are commonly used by the Visayans for drinking cups. From the great opercula of certain marine forms bracelets and other ornaments are carved, while the hard, strong, and beautiful murex shell is used in inlay and in the making of knives for rice-keeping. The land molluscs have been thoroughly classified, but much still remains to be done with the marine species.

Wild hogs are very abundant and as yet little known. Shrimps, crabs and lobsters form an important source of food supply. Mosquitoes are numerous in the wet lowlands. Bees are abundant, and wild honey and wax are gathered in considerable quantities. The number of species of ants is very large. Some of them inest dwellings-houses and swarm over the food. The termites, or so-called "white ants," inflict great damage on wooden buildings. PLAGUE OF LOCUSTS OCCASIONALLY, DURING A DROUGHT, RUN GROWING CROPS; IN DAMP WET WEATHER THESE INSECTS ARE DESTROYED BY A FANGUS GROWTH (EMPUSA GYRIAE) WITHIN THEIR BODIES.

The coral reefs, which are the foundation of the big islands, and the small atolls, are beautiful, and Guimaras, Cebu and Siquijor are completely covered with a thick cap of coral limestone.

Flora.—The rich and varied flora of the Philippines is essentially Malayan, combined with Chinese and Australian elements, but with sufficient individuality to constitute a sub-region, there being at least 769 species peculiar to the archipelago. More than two-thirds of the land surfaces are covered with forest, of broad-leaved trees, common among which are the bamboo, the coco and other palms, and the hanyan tree; but on the higher mountains, most of the 34 species of forest trees are of commercial or local value, among them are woods well suited for structural purposes, inside finishing, cabinet work and carriage making. Plants valuable for their fibre include the abaca, the Manila hemp, and the various leaves of which Manila hemp is made. There are gattepa-tetta, india-rubber and other plants and trees yielding gums, the banana, mango, and many other trees and plants yielding fruits; and various trees and plants yielding nuts, spices, oils and medicinals.

Climate.—A uniformly high temperature, excessive humidity, heavy rainfalls and violent tropical storms, known as typhoons or the "wind of the gods," characterize the archipelago. According to the mean annual temperature is about 80° F., the range of mean monthly temperature 6-48°, from 77° in January to 85-4° in May; and the range of extremes (during the period from 1881 to 1902) 39°, from 57° in February to 80° in May. The annual rainfall in accordance with the monthly variations in temperature at Manila the year is divided into three seasons: temperate (November, December, January and February), hot (April, May and June) and cold (July, August, September and October), during which months of the archipelago the mean annual temperature varies much more with the altitude than with the latitude, but the range in mean monthly temperature varies from 20° in February to 30° in July. At October Trindad on 7° 15' N. to 12°6' at Santo Domingo, Batan Islands, in 20° 28' N. The exactitude of the temperature also decreases appreciably from the sea-coast to the interior. The maximum temperature in Manila, 106° F., occurred on 18th November, 1881, and the minimum temperature, 57° F., on 15th June to the middle of October, when the winds blow from the south-west. During the period from 1865 to 1902 the annual rainfall varied from 35-6 in. in 1885 to 117-3 in. in 1887 when in the month of August. September and August two-thirds of the days are rainy, but in February, March and April only one-tenth of them are rainy. On Leyte Island, the coast of which is exposed to the occasional typhoons, the rainy season is from November to May, when the winds blow from the east or the north-east. In the year ending August 1903 the amounts of rainfall at 41 observation stations widely distributed throughout the archipelago varied from 47-6 in. at Zamboanga to 322 in. at Santa Cruz to 152 in. at Masinloc, on the west coast of central Luzon. The Philippines are visited on the average by twenty or more typhoons annually. About one-fifth of them occur in September. During January, February, March and April they are rare; in May, June and July they become increasingly common, and in August there is a falling off in the number, which reaches its maximum in September, gradually decreasing in October, November and December. The vortex of which has been known as the "green isle" is a vortex caused by winds which have passed over Manila, an immense amount of damage was done in the city. Two thousand persons lost their lives in Samar and Leyte during the great storm of 1897. The typhoon warnings sent out from the Manila observatory annually save heavy loss of life and property.

Soil.—The soil, usually of a reddish-brown colour, is for the most part provided with necessary inorganic elements. However occasionally there is also a mixture of disintegrated coral limestone.

Agriculture.—Agriculture is the principal industry. In 1903 about 40% of the working population were engaged in agricultural pursuits. The staple food, rice, is grown all over the islands. The native farmers are lazy and slow to appreciate the advantages of the methods recommended by the Americans. Only 5-6% of the land in the archipelago was in "farms" in 1903. The government of 1904, with a view to encourage agriculture, transferred to the province of La Laguna, Luzon, was the only province in which more than 90% of the land was included in "farms," and Cebú the only island in which more than 25% of the land was included in farms; in the province of Mindanao, the land included in "farms" was only 18.4% in Mindanado only 3.9%. There were 815,453 "farms" or individual holdings, but more than one-fifth of these were small parcels or gardens containing less than an acre each; about one-half contained less than 1/20 of an acre, and the average area was 0.07 of an acre. More than four-fifths of them were worked by owners, and the remainder chiefly by share tenants. The principal crops are hemp (abacá), sugar, tobacco, coco-nuts and rice. Most of the hemp (356,402 acres in 1902) is grown in south Luzon and in Samar and Leyte, but smaller crops are produced in Cebú, Mindanao, Marinduque, north Mindanao and south Negros; the crop became of commercial importance about 1800. Java tobacco is produced on Mindanao and northern Mindanao, and of the area of 112,895 tons. About two-thirds of the sugar is produced in Negros, but it is an important crop in the provinces of Pampanga and Tarlac, within the lowland basin of Luzon, also in the province of Batangus on the south coast of Luzon, in the south and east of Panay, and in Cebú. The production increased from about 6000 tons in 1855 to 300,000 tons in 1893, and for many years prior to 1887 it was a more important crop than hemp, but since the American government began to encourage its growth the hemp was grown in 1881, the yield for export was 115,955 tons. Approximately one-half of the tobacco, 77,632 acres yielding 37,485 lb. in 1902, is grown near the coastal town of Camarines, which is of inferior quality, in the neighbouring provinces of Union, Ilocos Norte and Abra, and in Panay, Cebú, Masbate and Negros. The natives chew betel nuts sparingly, and for medicinal purposes the betelnut is eaten by more than 60,000 acres. The rich soil of the lowlands of the province of Laguna is especially well adapted to the culture of the coco-nut palm, and since the American occupation considerable land in this province that had formerly been devoted to sugar
PHILIPPINE ISLANDS

has been planted with these trees. They thrive well also in most low districts along the coasts; in 1902 about 375,000 acres were devoted to the culture of them.

Rice is the staple food of the natives. When the Philippines were first occupied, they did not plant any crops other than rice, because of the great importance, and until the 19th century it was the chief article of export, but as the culture of the more profitable crops of hemp, sugar, and tobacco extended it became an article of import. As late as 1902, however, of the estimated output of rice the last product was small, and the consumption of rice very general. In some districts Indian corn is the staple food instead of rice, and the production of this cereal in small quantities for livestock is general. It is grown most extensively in the southern islands, and is also grown extensively in the north. In 1897 the export of rice from the archipelago was about 254,470. For several years prior to 1891, coffee, grown principally in the provinces of Cavitte, Batangas and Lepanto-Bonito, Luzon, was nearly as important a crop as tobacco, but between 1891 and 1893 most of the coffee plantations were destroyed by insects and disease. A small quantity of coffee is grown in the province of Benguet, Luzon, and is of superior quality. Cotton, the cultivation of which was discouraged by the Spanish government as a means of increasing the cultivation of tobacco, is a very small crop, except in the provinces of Hocos Norte, and Hocos Sur on the west coast of north Luzon; in 1902 these provinces alone produced 4,582 pounds of cotton. The tropical fruits grow wild but their quality is often inferior; those cultivated most extensively are mangoes and bananas. Grapes, blackberries, figs and strawberries have been introduced from the United States; they are grown successfully in a few places, but their cultivation has not increased. The natives care little for the garden vegetables common to Europe and America, but in the vicinity of Manila and other large centers of population the Chinese grow many of these for consumption by the European and American inhabitants.

With the exception of the water-buffalo, which is indispensable for agricultural purposes, the domestic animals are very inferior in quality and few in numbers. The horses, which are of Mexican, Spanish and Chinese origin, are small and poorly cared for; some American horses have been introduced for the purpose of improving the breed. The next cattle, which are of Australian and Indian origin, number about 27,000. Boars and hogs are numerous; about nine-tenths of them were destroyed by the rinderpest and the war at the close of the 19th century. Swine are numerous but they are of a kind known in the United States as "razorbacks." There is a large forest of near 2,000 acres near Marinduque and another near Marinduque duck-raising is of considerable importance, but the principal branch of the poultry industry consists in the raising of game-cocks for cock-fighting, which is the national sport.

Mineral Resources.—Numerous mineral deposits have been discovered, but little has been determined with respect to their value. Lignite is widely distributed, and there is a deposit of lignite in the vicinity of the town of Malabite, which is very likely rich. As the result of favourable indications extensive gold-mining operations have been instituted in the provinces of Benguet and Ambos Camarines in Luzon, and on the island of Mindanao. Copper is scarcely less widely distributed than gold, and the production of it awaits smelters and better facilities for transportation. There are extensive deposits of iron ore (magnetite and hematite) in the province of Bulacan, Luzon. Iron ore has been found in other provinces of Luzon and in the islands of Cebu, Panay and Marinduque. There are outcrops of lead in Marinduque and Cebu, and in Marinduque considerable silver is associated with the lead. Antimony is found in Ilocos Norte.

Manufactures.—The manufacturing industry consists mainly in preparing agricultural products for market, and in the production by the natives of wearing apparel, furniture, household utensils, and other articles required to supply their primitive wants. The most important factories are those for the manufacture of cigars and cigarettes, but most cigars and some of the cigarettes are made by hand. In the manufacture of sugar most of the mills in use extract only the juice of the sugar cane; only 73% of it was manufactured by 528 mills operated by steam; 17% by 470 mills operated by hand or by a carabao; and 10% by 71 mills operated by water-power. In the principal districts sugar is made from raw cane and clarified by refineries, but in other districts more primitive methods are employed. Most of the cloth which the natives wear is made in their own homes. The cotton and hemp which is manufactured in these islands is selected hemp fibres and is worn by both men and women; jute, which is made from a mixture of hemp and pineapple-plant fibres with or without the addition of some cotton and silk and is used for making women's dresses and men's shirts; pina, which is made from the fibres in the leaf of the pineapple-plant and is used for making women's garments, handkerchiefs and scarves. Nipa, made from the fibre of the agave or nipa plant and worn by women, is generally woven in small mats. Various kinds of buri, split bamboo and various grasses. Mats, rugs and carpets are made principally of split bamboo; chairs and beds of balings and other woods. The foundations of these mats are split buri (Corypha umbraciformis), cauang (Coryota onusta), pugahan (Coryota urens) and Indian corn. Other manufactures of the natives include vessels of various kinds, harnesses, indigo, or dyes, and a variety of drugs. Communications and Commerce.—The railway in the Philippine Islands was the line from Manila to Dagupan (120 m.) which was built by an English corporation under a guaranty of the Spanish government, and which was opened for traffic in 1887. There had been several other lines of smaller importance built and operated under the laws of the state of New Jersey, agreed to construct about 600 m. of railway in Luzon; and the Philippine Railroad Company, organized under the laws of the state of Connecticut, agreed to construct 460 m. in Mindanao. In 1906 there were in operation more than 300 m. in Luzon, 60 m. in Cebu and 50 m. in Panay. At the beginning of the American occupation the roads were in an embryonic stage; but in 1906 there were at least 400 m. of good roads. The Cagayan river, which is navigable for native boats 160 m. from its mouth, and for rafts 40 m. farther up, is an important highway of commerce in north Luzon. Many islands of inland water communication with small boats or bamboo rafts are afforded by the Pampanga, Agno, Abra, Pasing and Bicol rivers in Luzon, and by the Agusan and Rio Grande de Mindanao in Mindanao. There are also navigable streams in the Sulu archipelago. The principal ports of the islands are Manila, and its branch at Calayan, and Iloilo, and its branch at Cabanatuan. In 1907 the number of vessels engaged in trade was about 100. There were in the same period 350,000 passengers and 600,000 tons of freight handled by vessels of various kinds, including steamers, under the British, Spanish, American and German flags. The quantity of exports increased from $1,781,000 in the year ending 30th June 1899 to $2,914,000 in the year ending 30th June 1909, and the exports of the United States, during the same period from $20,501,430 to $30,918,357. A very large part of the trade is with the United States and Great Britain. The imports from Britain exceed those from the United States, but the imports from the United States are increasing. In 1905 the importation into Great Britain, and the total trade with the United States is greater than that with any other country. In 1909 8-5% of the imports were from the United States and 17-8% of the exports were for the United States; in 1906 16.4% of the exports were from the United States and 31.4% of the exports were for the United States. In 1909 free trade was established between the United States and the Philippines in all goods which are the growth, product or manufacture of these countries, with the exception of rice, except that a limit to the free importation from the Philippines to the United States in any one year is fixed on cigars at $15,000; on tobacco, at $25,000; on sugar, at $250,000; on hemp, at $10,000; and on tobacco, at $1,000,000; and on sugar, at $1,000,000. In the manufacture of these articles the United States is discouraged from importing more than 15% of wrapper tobacco, at $1,000,000; on tobacco, at $1,000,000; and on sugar, at $300,000 gross tons. In the case of manufactures the law provides that only those articles which do not exceed 10% in value of foreign material shall be admitted free.

Population.—The total population of the archipelago as enumerated in the census of 1903 was 7,653,426. Of this number 6,987,868 were classed as civilized and 647,740 as wild; 7,579,885 or 99.2% were native-born and 55,138 were foreign-born; 7,539,632 were of the Malayon or brown race, 42,907 were of the yellow race, 24,016 were of the black race, 14,271 were of the white race, and 15,419 were of mixed races. Of the black race 23,517, or 97.8%, were Negrillos, who are believed to be the aborigines of the Philippines. Nearly all of them live in a primitive state in the interior of Luzon, Panay, Mindanao and
Negros. They are very short of stature, 4 ft. 10 in. being about the average height of a full-grown man, and the women are shorter. Their colour is black, their skull decidedly round, their hair thick and frizzly, their legs thin and almost without calves, and their toes so prehensile that they can use them nearly as well as their fingers. They tattoo themselves and wear very little clothing; usually only a goring. They have no furniture except bowls, but roam about in groups of a few families. They are skilful with the bow and in throwing stones, and they can easily kindle a fire, even in the wet season, by rubbing together two pieces of dry bamboo. Their food consists principally of game, roots and wild fruits. The women, who do all the work, collect wax and honey, which are their principal staples in trade. Few Negritos live to be fifty years of age. The brown race, which came from the south in successive waves of immigration beginning in prehistoric times, is composed of twenty-three distinct tribes varying widely in culture, language and appearance; their languages however belong to one common stock and there is a general resemblance in physical features and in quality of mind. The great bulk of the population, approximately 96%, is included in seven Christian tribes as follows: Visayan, 3,210,030; Tagalog, 1,460,605; Ilocano, 803,942; Bicol, 566,365; Pangasinan, 343,686; Pampanga, 280,084; and Cagayan, 159,648. The Visayans are the principal inhabitants of the islands in the central part of the archipelago (Panay, Cebú, Negros, Leyte, Bohol, Samar, Masbate and Paragua) and on the north and east coasts of Mindanao; they were perhaps the most civilized people in the archipelago when discovered by the Spanish; by whom they were originally called Pintados because they were in the habit of painting their bodies; but since then their progress has been less rapid than that of the Tagalog—those who constitute the bulk of the population of Manila and central Luzon and the majority of the population of Mindanao—who are now the most cultured of the brown races in the Philippines. Most of the Ilocanos are in the western half of north Luzon; most of the Bicolos in south Luzon; most of the Pangasinens in the province of Pangasian, which borders on the Gulf of Lingayén; most of the Pampangans in the province of Pampanga, which borders the north shore of Manila Bay; and most of the Cagayáns in the valley of the Cagayán river. More than three-fourths of the wild population is included in the Moro, Igorot and Negrito tribes. The Igorots (197,038 wild and 13,582 civilized, the chief representatives of the last-mentioned, are the principal immigrants to the archipelago. They are the principal inhabitants of the provinces of Lepanto-Bontoc and Benguet in north Luzon and are numerous in the mountain districts of neighboring provinces. Among the wildest of them head-hunting is still a common practice; but the majority are industrious farmers laying out their fields on artificial terraces and constructing irrigation canals with remarkable skill. The Moros (275,224 wild and 2,325 civilized) were the last of the Malays to migrate to the islands; they came after their conversion to the Mahomedan religion, and their migration continued until the Spanish conquest. More than one-half of them are in Mindanao and they are the principal inhabitants of the small islands of Jolo, Basilan, Siasi and Tawi Tawi south-west of Mindanao. Slavery is common among them. They are generally miserably poor, cruel and haughty. Nearly three-fourths of the foreign-born and 97.5% of the representatives of the white race come from China. The mixture of the races is principally that of the Chinese with the Malays or the Spaniards with the Malays. More than half the representatives of the white race (1903) were Americans. Most of the inhabitants live in groups of villages. In 1903 there were 11,430 villages and nearly three-fourths of them contained fewer than 600 inhabitants each. Laoag in north Luzon with a population of 10,609, Hilo in Panay with a population of 15,562, Cagayan de Oro with a population of 18,338 and Nueva Caceres in south Luzon (10,201), were the only towns with a population exceeding 10,000; and Manila (219,028) was the only city. After the 1903 census many towns were enlarged by annexation of suburbs.

Government.—At the beginning of the American occupation, in August 1898, a purely military government was established; but in May 1899 the military authorities began the re-establishment of civil courts, and in July of the same year they began the organization of civil municipal governments. To continue the work of organizing and establishing civil government the president of the United States appointed in February 1900 a Philippine Commission of five members, with William H. Taft as chairman. On the 1st of September 1900 this body assumed the legislative functions of the central government at Manila; on the 4th of July 1901 the executive authority was, by order of the president, transferred from the military governor to Judge Taft, whom he had appointed civil governor; on the 6th of September 1901 the Philippine Commission, by authority of the president, established the four executive departments, of interior, commerce and police, finance and justice, and public instruction; and on the 29th of October 1901 the president appointed a vice-governor. The Congress of the United States, in an act approved on the 1st of July 1902, ratified and confirmed the government as thus established, but required that future appointments by the president of the governor, vice-governor, members of the commission and heads of the executive departments should be made with the consent of the Senate. The organic act contained a bill of rights, provided for the establishment of a popular assembly two years after the completion of a census of the Philippines, and more definitely provided for the organization of the judiciary. The first popular assembly, of 80 members, was opened at Manila on the 16th of October 1907, and since then the legislature has been composed of two branches, the Philippine Commission (five Americans and four, formerly three, Filipinos) and the Philippine Assembly. The members of the Assembly are elected by districts (the population of which is approximately equal) for a term of two years. A voter must be twenty-three years of age, must have been a resident of the municipality for six months, must not be a citizen or subject of any foreign country, and must possess at least one of the following qualifications: have been an office-holder under Spanish rule, own real estate worth 500 pesos, pay taxes amounting annually to 30 pesos, or be able to speak, read and write either Spanish or English. The legislature meets annually; a regular session is limited to 90 days, and a special session to 30 days.

Justice is administered principally by a supreme court, courts of first instance, and courts of justices of the peace. The supreme court consists of seven members, four Americans and three Filipinos; and the chief justice and associate justices of the supreme court are appointed by the president of the United States with the consent of the Senate. The judges of the courts of first instance are appointed by the governor with the consent of the Philippine Commission. A judgment of the supreme court of the Philippines which affects any statute, treaty, title, right or privilege of the United States may be reversed, modified or affirmed by the Supreme Court of the United States; an appeal to the Supreme Court of the United States may also be had in any case in which the value in controversy exceeds $25,000.

The most common form of provincial government is that by a governor, who is elected biennially by the municipal councillors in convention, and a secretary, a treasurer, a supervisor, and a fiscal or prosecuting attorney, who are appointed by the Philippine Commission. Each municipality is governed by a president, a vice-president, and a municipal council, all of whom are elected biennially by the qualified electors of the municipality. The Philippine "municipality" is an administrative area, often sparsely settled, is often called a town, and may be compared to a New England township; the municipalities are the units into which the provinces are divided. Each municipality is made up of barrios or small villages (about 13,400 in the entire archipelago) and of one, or more, more thickly peopled areas, each called a poblacion, and resembling the township "centre" of New England.

Education.—The establishment of an efficient system of elementary schools has been an important part of the administration. Under Spanish rule the Church established colleges and seminaries for training priests, but the Spanish system of secular schools for elementary instruction, established in 1665, accomplished little; the schools were taught by unqualified native teachers and the supervision of them was very lax. The American
system, established by the Philippine Commission in 1903, provides a course of instruction (in the English language) for 11 years: 4 primary, 3 intermediate and 4 secondary. In the intermediate and secondary departments there is a choice of six courses; general, teaching, farming, forestry, household, and household business. The administrative head of the system is the director of education, who is appointed by the commission, and who arranges the course of study, approves the plans for school houses, determines in what towns secondary schools shall be established and in what towns American teachers shall teach, divides the archipelago into school divisions and appoints a division superintendent in each, and supervises the examination of teachers and the application of the school fund. As such an office was an association was appointed by the commission. In each school division, of which there were 35 in 1908, the division superintendent appoints the teachers, prepares schedules of school estimates of school expenses, and approves all expenditures from the school funds. In each municipality there is a school board consisting of the president of the municipality and from four to six other members as the division superintendent shall determine; one-half of them are elected by the municipal council and one-half are appointed by the division superintendent. In 1902 there were 928 American teachers employed in the Philippine schools; the employment of American teachers is only a part of the policy, however, and by 1908 the number has been reduced to 795. In 1910 there were more than 6000 Filipino teachers who were teaching English to more than 500,000 pupils. The total number of children of school age is about 700,000. The insular government also makes annual appropriations for the maintenance of Filipino students at educational institutions in the United States. For the year 1908, $35,000 was voted. Besides the elementary schools there are at Manila the Philippine Normal School, the Philippine School of Arts and Trades, the Philippine School of Commerce and the school for the instruction of the deaf. In 1908 the legislature passed an act for the establishment of a university of the Philippines.

Finance.—Revenue is derived largely from customs duties and internal revenue taxes. In 1909 the receipts were $22,737,000, the expenditure $23,337,000, and the total bonded debt $16,000,000. (N. M.)

History.—The Philippine Islands were discovered by Magellan in March 1521. The first island on which he landed was Malhou, between Samar and Dinagat. Then sailing south he touched at Mindanao, from which he sailed north-west, past Bohol to Cebú. Here he found a good harbour in the bay on which the city of Cebú now stands. He made an alliance with the natives, who undertook to supply him with provisions. With his new allies he crossed to the little island of Mactan, where he was killed in a skirmish. A Portuguese by birth, he had been sailing in the employ of King Charles I. of Spain (the emperor Charles V.), with the object of proving that the Moluccas lay within that part of the world which Pope Alexander VI. and the treaty of Tordesillas (June 7, 1494) had given to Spain and not to Portugal. Magellan discovered his country the Archipelago of San Lazarus. The Spaniards, however, called the group the Islas de Poniente (Western Islands). The Portuguese called them the Islas de Oriente. The distinction was not accidental. To the Portuguese they constituted the eastern boundary of their sphere. From the Spanish point of view the islands were on the extreme western verge of the national domain. In 1529, by the treaty of Zaragoza, Spain relinquished to Portugal all claims to the Moluccas and agreed that no Spaniard should trade or sail west of a meridian drawn 29° east of the Moluccas. This was a plain renunciation of any rights over the Philippines, which lie several degrees west of the Moluccas. This fact, however, was ignored and in 1542 an attempt to conquer the Philippines was made by Ruy Lopez de Villalobos (c. 1500-1544). Villalobos chose to honour the heir-apparent of the Spanish throne by naming some of the islands which he discovered, west and north of Magellan’s discovery, the Islas Filipinas. After the accession of Philip II. (1555-1598) a much more important expedition was fitted out on the same lines. In 1565 under the supervision of the conquistador, Miguel Lopez de Legaspi (1523-1572). In the sailing directions, issued in 1561, for the use of this expedition the phrase “las Islas Filipinas” was used as applying to the entire archipelago. Starting on the 2nd of November 1564, from Navidad, with four ships built and equipped on the spot, Legaspi began an enterprise which entitles him to a place among the greatest of colonial pioneers. He was accompanied by five Augustinian friars and four hundred men. In 1565 he founded, on the island of Cebú, San Miguel, the first permanent Spanish settlement in the islands, destined to become the Villa de Santisimo Nombre de Jesus, later the city of Cebú. In 1571 the city of Manila was founded, not far from the coast, under the leadership of Miguel López de Legazpi. The conquest of the islands was facilitated by the fact that there were no established native states, but rather a congeries of small clan-like groups, the headship of which was hereditary. Legaspi was reinforced from time to time by small contingents of troops and friars. Although he encountered numerous obstacles, including famine and mutiny, the hostility and treachery of the natives and of foreigners, and the neglect of the home government, he laid a sure foundation for permanent Spanish occupation. By a combination of tact, courage and resourcefulness he won the hearts of the natives, repelled the Portuguese and, notwithstanding the great distance from Spain, established the new colony on a practical basis. Before his death in 1572 he had explored and pacified a large part of the island territory, had established trade, and had arrested the progress of Islamommedanism.

The conquest of the Philippines was essentially a missionary conquest. Inspired by apostolic zeal the friars braved the terrors of life in the remote villages, raised the natives from barbarianism and taught them the forms of the Christianity. As a result of their labours the Christian Filipinos stand unique as the only large mass of Asians converted to Christianity in modern times. The friars promoted the social and economic advancement of the islands, cultivated a taste for music, introduced improvements in agriculture and imported Indian corn and cacao from America. Tobacco was introduced by the government.

The colonial government was patterned on that of Spanish America. The powers of the governor-general were limited only by the audiencia or supreme court, of which he was president, and by the residencia or official investigation at the expiration of his term. The islands were subdivided into provinces under alcaldes mayores who exercised both executive and judicial functions. The-lavouirism and corruption that honeycombed the civil service of Spain frequently resulted in placing in responsible positions persons who were entirely unfit. Hairdressers were made into alcaldes, and sailors were transformed into gobernadores by the miraculous grace of royal decrees. The provinces were subdivided into pueblos, each under a native gobernadorcillo, elected annually. The permanent offices could be bought, sold and inherited. The mistake was made of paying very low salaries to the officials, who took this as a justification for illegal exactions. The difficulty of securing proper officials gradually resulted in the more important civil functions being handed over to the friars, who frequently exercised a benevolent despotism. In more than half of the twelve hundred villages there was no other Spaniard beside the priest. The Spanish language was practically unknown. It was far easier for the monks to learn the native dialects than to teach their parishioners Spanish. For two centuries and a half after the conquest there is little narrative history worth recording. There were border wars with rebellious savage tribes, attacks made by Chinese pirates seeking plunder or refuge, volcanic eruptions, earthquakes, tornadoes and the periodical visits of marauders from the southern islands.

In 1762, however, as an incident of the war between Spain and England, a British fleet of thirteen ships, under the command of Admiral Samuel Cornish (d. 1770) and Brigadier-British General William Draper (1721-1737) was sent to Occupation of the Philippines. The available Spanish army consisted of about 600 men, while the attacking force numbered 2929; the victor, Draper, was made a peer, and the fleet, commanded by Manuel Casas and on the 3rd of October the British entered the city. By the terms of the capitulation the whole of the archipelago was surrendered to the British and an indemnity of $4,000,000 pesos was to be paid. As there was no governor-general at the time, the British were obliged to treat with the acting governor, the Archbishop Manuel Antonio Rojo; but his authority was set aside by a war-party who rallied around Simon Anda y Salazar, a member of the audiencia. Anda proclaimed himself governor-general and practically
succeeded in confusing the British to Manila. At the close of the war the Philippines were returned to Spain. Manila was evacuated in March 1764.

For the first quarter of a century after the Spanish conquest the islands were allowed free trade. Then came the familiar economic restrictions, limiting commerce to a fixed amount annually, and effectively checking economic development. In 1597 direct trade between the Philippines and South America was prohibited. In 1593 trade between the Philippines and Mexico, the only route open between the colony and Spain, was limited to two native annually, the ships not to exceed two tons burden. The result was that the command of the Acapulco galleon was rarely worth less than $50,000. The passenger fare from Manila to Acapulco, at the end of the 18th century, was $1,000. This monopoly lasted until the Mexican War of Independence forced the Spanish government to regard the Philippines as being in the East instead of the West. Spain’s colonial policy was not based on an exaltation of the commercial ideal. However much the administrators may have fallen short in actual practice, the Spanish ideal was to preserve and civilize the native races, rather than to establish lucrative trading posts where the confined they might be, with the natives or with the ships. The laws which provided elaborate safeguards for the protection of the Indians were, to a large degree, nullified by the just for gold and silver and the consequent demand for labourers in the mines.

In the Philippines the humane policy of the home government had no such powerful obstacles to contend with. Business was not developed. The natives were allowed to live the indolent life of the tropics. Compared with the results of English or Dutch colonization the conversion and civilization of the Filipinos is a most remarkable achievement. Notwithstanding the undeniable vices, follies and absurd illiteracies of the Spanish colonial régime, the Philippines were the only group in the East Indies that improved in civilization in the three centuries following their discovery. The chief defect in the Spanish Philippine policy was that while it made converts it did not make citizens. Self-reliance, free-thought and mental growth were not encouraged. Progress in scientific knowledge was effectively blocked by the friars. Their presses confined their activities to the production of catechisms, martyrologies and handbooks in the native languages after the fashion of the presses of Mexico. Five hundred such works were printed and distributed in Manila alone before 1800. To reach the masses, unfamiliar with Spanish, manuals of devotion and outlines of Christian doctrine were translated into the various native languages. Even in the Philippines itself, no part was translated or published. A knowledge of reading and writing was generally diffused throughout the group.

The era of discontent may be said to have begun in 1825 when the loss of her colonies on the mainland of America caused Spain to take a more immediate interest in the Philippines, and increased emigration to the islands. Between 1840 and 1872 thirty newspapers were founded. The introduction of secular books and papers, more or less surreptitiously, helped to spread the seeds of sedition. In 1852 the Spanish Filipino Bank was established. In 1856 foreign trade, higher than in any other colony, was permitted to enter the port of Iloilo, and foreign traders were allowed to open branch houses outside of the capital. The change in Spain’s economic policy, including an attempt to exploit the coalfields and to encourage both agriculture and commerce, helped to awaken hitherto dormant elements. In 1861 the Jesuits had opened a college in Manila for the education of Spanish youth. In 1768 they had been expelled. In 1859 they were permitted to return on the understanding that they were to devote themselves to education.

The Spanish Revolution of 1868 caused a further influx of Spaniards and a second introduction of the pernicious “spoils system.” With every change of aid came a new lot of hungry politicians anxious to fill universal offices. The opening of the Suez Canal in 1869, followed by the establishment of direct steam communication between Spain and the Philippines, sounded the death knell of the peaceful missionary era and brought about the definite entry of the islands into the world of commerce and progress.

The friars, by perpetuating medieval conditions in a country that was now being opened to contact with the civilized world, increased the feeling of discontent. The natural result was a violent conflict. The more advanced Filipinos desired the fulfillment of the decrees of the Council of Trent whereby the incum- bencies in Christianized towns and villages should be held by regular clergy and not by friars. Filipinos had for generations been ordained into priesthood although not received into the monastic orders. This measure was really aimed at the political and economic supremacy of the Spanish-born friars, who had by this time acquired 400,000 acres of agricultural land, more than half of it in the vicinity of Manila. The agrarian question added to the growing discontent. All the revolutions began in the province of Cavite, where the friars owned 125,000 acres.

In 1872 the secret agents of the friars induced the native garrison at Cavite to mutiny and then give the friars an excuse to press for vigorous action. The mutiny was not successful, but Father Burgos, the leader of the reform party, was publicly garrotted by the Spanish priests; and the native clergy were declared to be incapable of being the custodians of souls. Several of the richest and best educated Filipinos were convicted of treason and banished.

With the increased facilities for European travel Filipinos began to visit Europe and return with new and broader notions of life. The most distinguished of the travellers was José Rizal (1861-1896). Born in Calahin, in the province of Luzon, of pure Tagalog parentage, he attended the newly reopened Jesuit university in Manila. He was then sent to Europe to complete his studies, first in Madrid, where he became a doctor of medicine, and later in Germany, where he received the degree of Ph.D. He came into touch with advanced methods of scientific research, acquired great ability as a writer, kept perception of truth and an unflinching realization of the defects of his own people, and the unpleasant but essential fact that to have better government they must first desire it. His propaganda, aimed at the small body of Filipinos who had sufficient education to appreciate political satire, was very effective. His most famous novel, Noli me tangere, was published in 1886. In this he drew a masterly picture, not only of the life and immorality of the friars but also of the insolent Filipino chiefs or caciques, subservient to the powers above, tyrannical to those below, superstitious, unprogressive and grasping. Caciquismo or “local government” was the worst vice of the Filipinos, the prime feature of village life in the islands during the entire period of Spanish rule and existed long before their arrival.

The campaign of Rizal, Marcelo del Pilar, Graciano Lopez Jaena and Apolinario Mabini, the leaders in the “Young Filipino Party,” was a protest against both the domination of the friars and economic and administrative caciquismo. To escape the vengeance of the friars, Rizal was obliged to flee to Europe. In 1892 he returned to the islands on the assurance of the governor, Eulogio Despujol y Dusay, that he might live there in peace. His enemies, however, succeeded in having him arrested on a charge of treason. Meanwhile, the “Labor party” had assumed the title of Liga Filipina. Its object had been to procure, by pacific means, several reforms in the government of the islands, the chief of which were the expulsion of the friars, and the withdrawal of the governor-general’s arbitrary power to deport Filipinos. The friars imported Despujols for Rizal’s life but he persistently refused their demand, and met the case half-way by banishing Rizal to Mindanao. Incensed by the failure of their plot, the friars obtained the recall of Despujols.

The new governor, Ramón Blanco, was like Despujols and many of his predecessors, humane at heart, but he could do little more than hold in check the tyrannical schemes of the clergy. The banishment of Rizal continued the reform party that peaceful endeavours was futile.

A secret organization, the Katipunan, was therefore started to secure reforms by force of arms. It was founded by Andres
Bonifacio, a schoolmaster of Cavite. In 1895-1896 the friars acting as spies for the government, obtained the banishment of the natives, who were kept under armed guard.

On the day after the Katipunan conspiracy had been brought prematurely to light by a traitor, three hundred prominent Filipinos were lodged in prison. This precipitated the revolt. The insurrectos attacked the civil guard outside the city, but were unsuccessful. A week later some hundreds of insurgents attacked the powder magazine at San Juan del Monte, but were completely routed. Four of their chiefs were taken prisoners and executed in Manila. Ten days after the plot was discovered Manila and five other provinces were officially proclaimed in a state of siege. The insurrectos concentrated their energies upon Cavite province. Several villages fell into their hands. The insurgent commander-in-chief was Emilio Aguinaldo. He was born in 1869 in Cavite, son of a native farmer of considerable ability, and of a half-caste mother whose father was a Chinaman. After attending the Tagalog school at Cavite he entered the Jesuit College in Manila but did not graduate. In 1891 he became municipal alcalde of Cavite, and later joined the Katipunan.

The government was in a difficult position. General Blanco had extremely few European troops at his disposal, and it was doubtful how far native troops could be trusted. Reinforcements were on the way from Spain, but the demands of Cuba had already depleted the Peninsula of the best fighting material. Blanco, blamed for not acting at once, was recalled. In December 1896 General Camilo Garcia de Polavieja (b. 1838) arrived as his successor, with General Jose Lachambre (b. 1836) as chief of staff. Before Blanco left he had released Rizal and allowed him to go to Spain, but the friars caused his arrest and he was sent back to Manila, where he was executed by Polavieja's orders in December 1896.

Lachambre took the field in Cavite with energy and succeeded in quelling the rebellion in that province. He was then despatched north. Numerous small battles were fought with Aguinaldo and the insurgents, who were repeatedly defeated only to reappear in other places. Polavieja's demand for more troops having been refused, he resigned, and was succeeded in the spring of 1897 by General Fernando Primo de Rivera. Hostilities continued, but the wet season set in, making operations extremely difficult. Before Primo de Rivera could make much headway against the insurgents affairs in Cuba became so serious that the Spanish government cabled him that pacification was most urgently desired. As a result he suspended operations and signed the treaty of Biacabato (Dec. 12, 1897), by which Aguinaldo and thirty-five of his chief followers were allowed to retire to Hongkong with a cash indemnity of $200,000 pesos. The Madrid government refused to confirm the terms of peace, and the peace rejoicings in Manilla were followed by the persecution of all those who were known to have sympathized with the movement.

On the 15th of February 1898 in Havana harbour, the U.S.S. "Maine" was blown up. On the 15th of March Primo de Rivera, learning that the American Commodore George Dewey was mobilizing his fleet in the harbour of Hongkong, called a council at which the Spanish Admiral Patricio Montojo (b. 1839) stated that, in the event of a conflict, his own fleet would be inevitably destroyed. Primo de Rivera was now recalled and General Basilio Augusti (b. 1840) took his place. With a new governor-general all plans had to be reconsidered. Before suitable defences could be made, word came from Hongkong that Dewey had started for Manilla and Montojo hurriedly sailed from Subig Bay to Cavite, barely in time to anchor before Dewey arrived. Few among his crew understood handling a gun properly, and owing to the poor care which his vessels had received they were actually inferior to the individual vessels of the American squadron. Commodore Dewey arrived in the Bay of Manila on the 1st of May, and totally destroyed or disabled the Spanish fleet. The surrender of the city was refused. The Americans occupied Cavite. The battle of Manilla Bay and the defeat of the Spanish fleet destroyed the prestige of Spain throughout the islands. Insurrections began in nearly every province. Aguinaldo and his friends were allowed to come to Cavite in an American transport. With the arrival of Commodore Merritt, who allowed arms to be supplied him, Aguinaldo successfully renewed his campaign against the Spaniards until practically all Luzon, except the city of Manilla and suburbs, was in his control. Reinforcements arrived, and on the 13th of August Manilla was taken by the Americans, under General Wesley Merritt (b. 1836).

The refusal of General Merritt to permit Aguinaldo's troops to enter Manilla created resentment on the part of the Filipinos. A so-called constitutional convention was held at Malolos, and a constitution was adopted. At the same time the Visayan Republic was organized, and it professed allegiance to Aguinaldo. After Aguinaldo's government the Visayan government was able to maintain order, and the whole country was subject to the looting of robber bands. The treaty of peace between the United States and Spain, by which the Philippine Islands passed into the hands of the former, was signed in Paris on the 10th of December 1898, but it was not confirmed by the Senate until the 6th of February 1899. During this period the Filipino army remained under arms. On the 4th of February hostilities broke out between the Americans and the Filipinos. The latter were defeated on the 5th, at Paco, with heavy loss. The American troops, now under General E. S. Otis (b. 1838), following up the enemy, drove them out of Malolos and then withdrew to Manila to await reinforcements, which brought the total American force up to about 60,000 men. It is unnecessary to trace in detail the gradual conquest of the islands, or the hundreds of engagements, often small, between the rebels and the Americans. Owing to the nature of the country, and the hope of securing independence from a possible overthrow of the Republican party in the United States, the war was prolonged for two or three years. With the capture of Aguinaldo on the 23rd of March 1901, the resistance became little more than that of guerrillas.

The civil government was introduced as fast as possible. During 1899 the Schurman commission, headed by Dr. Jacob G. Schurman of Cornell University, was sent by President McKinley to report on the state of affairs. In February 1900 a second and more powerful commission was appointed, consisting of Judge W. H. Taft, Professor D. C. Worcester (b. 1866), General L. E. Wright (b. 1846), Mr. H. C. Ide (b. 1844), and Professor Bernard Moses (b. 1846). Under the presidency of Mr. Taft it began to exercise a legislative jurisdiction in September 1900. Its first act was to appropriate $1,000,000 for the construction and improvement of roads. It next provided for the improvement of Manilla harbour, which involved an expenditure of $3,000,000. The fifth act extended to the islands the benefits of a civil service based on merit. In 1901 a general school law was passed under which 1000 American school teachers were introduced. They were scattered among 500 towns, to teach 2500 Filipino teachers English and modern methods of school teaching. Other legislation provided for the organization of a judiciary, a supreme court, the enactment of a code of civil procedure, the establishment of a bureau of forestry, a health department, and an agricultural bureau and a bureau of constabulary, made up of native soldiers officered by white men. Ladronism was very widely distributed under Spanish rule, and the old guardia civil committed outrages almost equal to those of the brigands themselves. The new constabulary has been eminently successful in maintaining law and order. Great progress has been made in the scientific mapping of the islands.

On the 4th of July 1901 the office of military governor was abolished, the military forces being largely recalled, and the part remaining being made henceforth subordinate to the civil authorities. Mr. Taft became governor-general. A general amnesty was granted to all rebels and political prisoners who would take the oath of allegiance to the United States. On the 1st of July 1902 President
PHILIPPOPOLIS

Roosevelt signed an act establishing the civil government of the Philippines and providing for a new legislative body. A census was authorized and was taken in 1903. The act of 1902 also authorized the purchase of land belonging to the friars. Although among such an ignorant and diversified body as that of the Filipinos public opinion can hardly be said to exist, there is no doubt that the hatred of the friars was practically universal. When the revolution came the members of the four orders had to flee for their lives, although the people who were killed or imprisoned those they could catch were generally good Catholics. As the insular government could not safely allow the friars to return to their parishes the friars’ lands were bought for $7,000,000. Mr Taft managed the delicate task of conducting negotiations with the Vatican without arousing the hostility of either Catholics or Protestants. On the 1st of February 1904 General L. E. Wright became governor. He was succeeded in 1905 by Mr H. C. Ide, who was succeeded by General James T. Smith in 1906. The elections for the first Philippine Assembly were held on the 30th of July 1907, and 31 Nationalists, 16 Progressists, 33 Independents and others were elected. It was not until 1917 that the legislature was composed of men elected by the voters at large. In many districts the Nationalists’ candidates promised that if they were returned immediate independence would follow. When the Assembly met it became apparent that the great majority were more anxious to act as a dignified branch of the legislature than to maintain consistency with their pre-election declarations. The legislature convened for its second session on the 1st of February 1909. During this session 72 laws were passed, of which 23 had been introduced by the Commission and 49 by the Assembly. Among the acts was one providing for the continuation of Spanish as the official language of the courts until 1913; an act providing for bankruptcy; and an act fixing the age of majority at 21 years.

Governor Smith left the islands in May 1909 and was succeeded by W. Cameron Forbes. On the 6th of August 1909 the Payne and Colton bills became law, greatly promoting trade between the Islands and the United States (see Communications and Commerce). On the 2nd of November 1909 delegates were elected for the second Philippine Assembly. (H. Bt.)

PHILIPPINOS (Bulgarian, Pelidose; Turkish, Felide), the capital of Eastern Rumelia, and of the department of Philippopolis, Bulgaria; situated in the midst of picturesque granite eminences on the right bank of the river Maritsa, 60 m. E.S.E. of Sofia and 07 m. W.N.W. of Adrianople. Pop. (1906) 45,572, of whom a large majority are Bulgarians, and the remainder chiefly Turks, Greeks, Jews, Armenians or gipsies. Philipopolis is on the main railway from Vienna to Constantinople, via Belgrade and Sofia. The Maritsa is navigable up to this point, and as the city has communication by rail both with the port of Dëddagatch on the Mediterranean and that of Burgas on the Black Sea, and is situated in a remarkably fertile country, it has become the chief commercial centre of southern Bulgaria, and is the seat of both Greek and Bulgarian archbishops. The residences of the richer Greeks and Bulgarians occupy the slopes of the largest eminence, the Jambaz-tepe, in the centre of the city; between it and the Nobet-tepe, from the summit of which there is a magnificent view of the city, is the Armenian quarter; near the bridge over the Maritsa is the poorer Turkish quarter; and south-west of the Jambaz-tepe there is a suburb of villages. On the Bumburni a monument has been erected by the Russians in commemoration of the war of 1877, and near this is the new palace of the king of Bulgaria. The Sahmet-tepe is crowned by a clock-tower. Not far from it are the beautiful Exhibition Park laid out in 1892 and the fine Jami Mosque. Near the Maritsa are the remains of the ancient konak (palace) of the Turkish pashas, the public park formed by the Russians in 1877, the gymnasium, and the new Greek cathedral. The city has a large commerce in rice, attar of roses, and cochons; other exports being wheat, wine, tobacco, alcohol and hides.

Philipopolis, a Thracian town, was captured by Philip V of Macedon and made one of his frontier posts; hence its name of Philipopolis, or "Philip's City." The town was an important station on the overland route from the Romans Philipopolis or Trumonita became the capital of Thrace; and, even after its capture by the Goths, when 100,000 persons are said to have been slain, it continued to be a flourishing city till it was again sacked by the Bulgarians in 1205. It passed under Turkish rule in 1365; in 1818 it was destroyed by an earthquake; and in 1846 it suffered from a severe conflagration. During the war of 1877-78 the city was occupied by the Russians (see also BULGARIA: History).

PHILIPSBURG, a town of Germany, in the grand duchy of Baden, situated on the railway Bruchsal—Germersheim. Pop. (1905) 2625. It has manufactures of tobacco and cigars, and some trade in cattle and hops. Phildsburgh, formerly an important fortress, originally belonged to the ecclesiastical principality of Spires, and was named Udenheim. In 1338 it was surrounded with walls by bishop Gerhard. A later bishop of Spire, Philipp Christoph von Stötern, made the place his residence early in the 17th century, strengthened the fortifications, and renamed it PhilipSBURG after himself. At the peace of Westphalia in 1648 the French remained in possession of the town, but in 1679 it was restored to Germany, and though again captured by the French in 1688 it was once more restored in 1697. In 1734 the dilapidated fortress fell an easy prey to the French under Marshal Berwick, who nevertheless lost his life beneath its walls. It was restored to Germany in 1735 and was again besieged by the French in 1799. The town was assigned to Baden in 1803.

See Nopp. Geschichte der Stadt PhilippSBURG (PhilippSBURG, 1881).
PHILIPPOS, MARCUS JULIUS, Roman emperor A.D. 244 to 249, often called "Philip the Arab," was a native of Bostra in Arabia Trachonitis. Having entered the Roman army, he rose to be praetorian prefect in the Persian campaign of Gordian III, and, invincible to the soldiery, was the young emperor, raised by them to the purple (244). Of his reign little is known except that he celebrated the secular games with great pomp in 248, when Rome was supposed to have reached the thousandth year of her existence. A rebellion broke out among the legions of Moesia, and Decius, who was sent to quell it, was forced by the troops to put himself at their head and march upon Italy. Philip was defeated and slain in a battle near Verona. According to Christian writers, he was a convert to Christianity.

Suet. Aurelius Victor, Caesar, 28; Eutropius, i. 3; Zonaras, xii. 19.

PHILIPPS, AMBROSE (c. 1675-1749), English poet, was born in Shropshire a member of a Leicestershire family. He was educated at Shrewsbury school and St John's College, Cambridge, of which he became a fellow in 1709. He seems to have lived chiefly at Cambridge until he resigned his fellowship in 1708, and his pastoral sonnets probably belong to this period. He worked for Jacob Tonson the bookseller, and his Pastoral Sonnets, with the pseudonym of Thomas Whitt, and a friend of Steele and Addison. In No. 22, 23, 30 and 32 (1713) of the Guardian he was injudiciously praised as the only worthy successor of Spenser. The writer of the papers, who is supposed to have been Thomas Tickell, pointedly ignored Pope's pastoral sonnets. In The Spectator Addison applauds him for his simplicity, and for having written English eclogues unencumbered by the machinery of classical mythology. Pope's jealousy was roused, and he sent an anonymous contribution to the Guardian (No. 40) in which he drew an ironical comparison between his own and Philip's pastoral sonnets, censuring himself and praising Philip's worst passages. Philips is said to have threatened to come to Pope with a rod he kept bung up in his garden, a picture of Byron's or my house for the purpose. It was at Pope's request that Gay burlesqued Philips's pastoral sonnets in his Shepherd's Week, but the parody pleased by the very quality of simplicity which it was intended to ridicule. Samuel Johnson describes the relations between Pope and Philips as a "perpetual reciprocation of malevolence." Pope lost no opportunity of scoffing at Philips, who figured in the Bathos and the Dunciad, as Mazer in the Characters; and in the "Instructions to a purter how to find Mr Cull's authors" he is a "Pindaric writer in red stockings." In 1718 he started a Whig paper, The Freethinker, in conjunction with Hugh Boulter, then vicar of St Olave's, Southwark. He had been made justice of the peace for the two parishes, commissioner for the lottery, and when Boulter was made archbishop of Armagh, Philips accompanied him as secretary. He sat in the Irish parliament for Co. Armagh, was secretary to the lord chancellor in 1726, and in 1733 became a judge of the prerogative court. His patron died in 1742, and six years later Philips retired to London, where he died on the 18th of June 1749. His contemporary reputation rested on his pastoral sonnets and epistles, particularly the description of winter addressed by him from Copenhagen (1770) to the earl of Dorset. In T. H. Ward's English Poets, however, he is represented by two of the simple and charming pieces addressed to the infant children of Lord Carteret and of Daniel Pelletney. These werecollected by Swift as "little flams on Miss Carteret," and earned for Philips from Henry Carey the nickname of "Nabm-Pamby."

Philips's works are an abridgment of Bishop Hacket's Life of John Williams (1700); The Thousand and One Days; Persian Tales and other works by him; also two of his plays, The Trestless (1712), an adaptation of Racine's Andromaque; The Briton (1722); Humphrey, duke of Gloucester (1723). Many of his poems, which included some translations from Sappho, Anacreon and Findar, were published separately, and a collected edition appeared in 1748.

PHILIPPS, JOHN (1675-1708), English poet and man of letters, son of Dr Stephen Philips, archdeacon of Shropshire, was born at his father's vicarage at Banston, Oxfordshire, on the 30th of December 1766. He was educated at Winchester and Christ Church, Oxford. He was a careful reader of Virgil and of Milton. In 1701 his poem, The Splendid Shilling, was published without his consent, and a second unauthorized version in 1705 induced him to print a correct edition in that year. The Splendid Shilling, with Addison in The Tatler called it "the finest burlesque poem in the British language," recites in Miltonic blank verse the miseries consequent on the want of that piece of money. Its success induced Philips to the notice of Robert Harley and Henry St John, who commissioned him to write a Troy counterblast to Joseph Addison's Campaign. Philips was happier in burlesquing his favourite author than in genuine imitation of a heroic theme. His Marlborough is modelled on the warriors of Homer and Virgil; he rides precipitate over heaps of fallen horses, changing the fortune of the battle by his own right arm. Cyclo (1708) is modelled on the Georgics of Virgil. Cœanna, a translation of the Georgics, became his best known work. He was for many years a contributor to the Gentleman's Magazine, and some of his anonymous verses on literary life and its characters, with Presbyterian traditions in both religion and politics, became an ardent admirer of the king and his church policy, and in 1647 married James Philips, a Welsh royalist. Her home at the Priory, Cardigan, became the centre of a "society of friendship," the members of which were known to one another by fantastic names, Mrs Philips being "Orinda," her husband "Antenor," Sir Charles Cotterell "Polarchus." The "matchless" Orinda, as her admirers called her, posed as the apostle of female friendship. That there was much solid worth under her affectations is proved by the respect and friendship she inspired. Jeremy Taylor in 1659 dedicated to her his "Discourse on the Nature, Offices and Measures of Friendship," and Cowley, Henry Vaughan the Silurist, the Earl of Roscommon and the Earl of Cork and Orrery all celebrated her talent. In 1662 she went to Dublin to pursue her husband's claim to certain Irish estates, and there she completed a translation of Cornelle's Pentée, produced with great success in 1663 in the Smock Alley Theatre, and printed in the same year both in Dublin and London. She went to London in March 1664 with a nearly completed translation of Cornelle's Horace, but died of smallpox on the 22nd of June. The literary atmosphere of her circle is preserved in the excellent Letters of Orinda to Polarchus, published by Bernard Jolivet in 1705 and 1709. "Polarchus" (Sir Charles Cotterell) was master of the ceremonies at the court of the Restoration, and afterwards translated the romances of La Calprenède. Mrs Philips had two children, one of whom, Katharine, became the wife of Lewis Wogan of Boulton, Pembroke. According to Mr Gosse, this lady may have been "Joan Philips," the author of a volume of Female Poems . . . written by Ephelia, which are in the style of Orinda, and display genuine feeling with very little reserve.

PHILISTINES, the general name for the people of Philistia (Ass. Pālāṣu; Pālīṣu; Eg. p-r-s-i), a district embracing the rich lowlands on the Mediterranean coast from the neighbourhood of Gerar to the upper Orontes. The term is often applied to the people of the Philistia, in a sense equivalent to "the enemy," as early as the begining of the 17th century, and later as a term for a bailiff or a sheriff's officer, or merely for drunken or vicious people generally. In German universalists the townsfolk
PHILISTINES

of Jaffa (Joppa) to the Egyptian desert south of Gaza (on the subsequent extension of the name in its Greek form Palaestina, see Palestine).

1. Egyptian Evidence.—The name is derived from the Parusati, one of a great confederation from north Syria, Asia Minor and the Levant, which threatened Egypt in the XXth Dynasty. They are not among the hordes enumerated by Xenophon. If. Mere- nephth, in the year of Ramses III (c. 1200 B.C.) the Parusati held a prominent place in a widespread movement on land and sea. The Syrian states were overwhelmed and the advance upon Egypt seemed irresistible. Rameses, however, collected a large fleet and an army of native troops and mercenaries and claimed decisive victories. The Egyptian monuments depict the flight of the enemy, the heavy ox-carts with their women and children, and the consignment of their ships. But the sequel of the events is not certain. Even if the increasing weakness of the Egyptian Empire did not invite a repetition of the invasion, it could have allowed the survivors to settle down, and about a century later one of the peoples formerly closely allied with the Parusati is found strongly entrenched at Dor, and together with the more northerly port of Byblos treats with scant respect the traditional suzerainty of Egypt. That some definite political changes ensued in this age has been inferred on other grounds, and the identification of the Parusati with the Philistines may permit the assumption that the latter succeeded in occupying the district with which they have always been associated.

The Egyptian monuments represent the Parusati with a very distinctive feather-head-dress resembling that of the Lycians and Mycenaans. Their general physiognomy is hardly Cilician or Hittite, but European. Their arms comprise two short swords, a longer spear, a round shield, and they sometimes wear a coat of mail; a curious feature is their tactics of fighting in a circle of protecting shields. The charioteers resemble the Hittite with two crossed receptacles for the weapons, but obviously these were not used by the Parusati alone. On archaeological grounds the Parusati have been connected with the people of Kefti, i.e. Mycenaean of Crete, although a wider application of this term is not to be excluded.

2. History. — Biblical tradition, too, has recognized the Philistines as immigrants from Caphtor (Amos i. 7). They appear in the pre-Mosaic age (Gen. xxii. 34, xxvi.); at the Exodus of the Israelites (Ex. xii. 17, xv. 14), and the invasion of Palestine. They are represented as a confederation of five cities (Ashdod, Ascalon [Ashkelon], Ekron, Gath and Gaza) which remained unconquered (Joshua xiii. 3 sqq.; Judges iii. 3; contrast Joshua xv. 45–47, xx. 43). The institution of the Hebrew monarchy (c. 1000 B.C.) followed upon periods of Philistine oppression (Judges iii. 31, x. 7, xi. 11, xiii. 1–5; see SAMSON; ELIJAH; SAMUEL; SAUL; DAVID). The subjugation of them is ascribed to the people called by the students Philister: they were "outsiders," the enemy of the chosen people. It is supposed that this use arose in 1693 in Jena after a "town and gown" row in which a student had been killed and a sermon preached on the text "the Philistines be my noise, and mine enemy." The term "Philistine" (see Quarterlies of April 1890 and April 1892) is quoted in the New English Dictionary). "Philistine" thus became the name of contempt applied by the cultured to those whom they considered untouchable in intellect and taste, and was first so used in English by Carlyle, and Matthew Arnold ("Heinrich Heine," 1865) gave the word its vogue and its final connotation, as signifying "inaccessible to and impotent of imitation."" 1

1 So the Papyrus first published by W. Gösenscheff (Rec. de traduct., xxi. 74 sqq.), on which see A. Erman, Zeit. f. saggy. Sprache, pp. 1–14 (1900); W. M. Müller, Middlet, d. vorderasiatischen, Gesell, pp. 14 sqq. (1900); J. H. Breasted, Hist. of Egypt, pp. 513 sqq.; Historical Records, iv. 274 sqq.; H. W. Hogg, in the Theolog. Series I. of the publications of university of Manchester, p. 90 sqq. to Samuel (1 Sam. vii. 13), Saul (xiv. 47), and David (2 Sam. viii. 1; for Solomon see 1 Kings x. 20); but they evidently recovered their independence, and we find that twice within a short time the northern Israelites lied siege to the border fortress of Gibbethon (1 Kings xv. 27, xvi. 15). Although this place has not been identified, it is mentioned in a list of Danite cities (Joshua xxi. 30, 34, 36; 1 Chronicles viii. 23), names of importance for the history. Somewhat later the evidence becomes fuller, and much valuable light is thrown upon the part which the Philistine coast played in the political history of Palestine. Gaza, the most southerly and famous of the Philistine towns, was the terminus of the great caravan-route from Edom and south Arabia, with whose Bedouin it was generally on good terms. It was "the outpost of Africa, the door of Asia" (G. A. Smith), the stepping-off point for the invasion of Egypt, and the fortress which, next in importance to Lachish, barred the maritime road to Phoenicia and Syria. It is necessary to realize Gaza's position and its links with trading centres, since conditions in the comparatively small and desert land of Judah depended essentially upon its relations with the Edomites and Arabian tribes on the south-east and with the Philistines on the west. 2 Jehoshaphat's supremacy over Philistines and Arabs (2 Chron. xxiv. 11, partly implied in 1 Kings xxii. 47) is followed by the revolt of Libnah (near Lachish) and Edom against his son Jehoram (2 Kings vii. 20, 22). The book of Chronicles mentions Philistines and Arabs, and knows of a previous warning by a prophet of Maresiah (east of Lachish; 2 Chron. xx. 37, xxi. 16). In like manner, the conquests of Uzziah over Edom and allied tribes (2 Kings xvii. 23, see 2 Chron. xxvi. 7) and over Gath, Ashdod and Jabneh (ibid. c. 6) find their sequel in the alliance of Samaria and Damascus against Ahaz, when Edom recovered its independence (so read for "Syria" in 2 Kings xvii. 6), and the Philistines attacked Beth-shemesh, Aijalon, Timnah, &c. (2 Chron. xxviii. 17 sqq.). These notices at least represent natural conditions, and the Assyrian inscriptions now are our authority. Tiglath-pileser IV. (734 B.C.) marched down and seized Gaza, removing its gods and goods. Its king Hanun had fled to Muṣri, but was pursued and captured; Ascalon, Judah and Edom appear in a list of tributaries. Muṣri was entrusted to the care of the Arabian Idhibi'il (of the desert district), but continued to support anti-Assyrian leagues (see Hoshea), and again in 720 (two years after the fall of Samaria) in rebellion with Riblash. Assyria under Sargon defeated the southern confederation at Rapibi (Raphia on the border of Egypt) and captured Hanun; the significance of the victory is evident from the submission of the queen of Arbei (Arabia), the Sabaeans Itamara, and Muṣri. This Muṣri appears to have been a district outside the limits of Egypt proper, and although tribes of the Delta may well have been concerned, its relations to Philistia agree with the independent biblical account of the part played previously by Edom and Arabian tribes (see MIZRAIM). But the disturbances continued, and although desert tribes were removed and settled in Samaria in 715, Muṣri and Philistia were soon in arms again. Ashdod (see Isa. xx.) and Gath were taken and sacked, the people removed, and fresh colonies were introduced. Judah, Edom and Moab were also involved, but submitted (711 B.C.). Scarcely ten years passed and the whole of Palestine and Syria was again torn with intrigues. Sennacherib (Sargon's successor in 705) marched to the land of the "Hittites," traversed

2 See G. A. Smith, Hist. Geog. of the Holy Land, chs. ix. sqq.; and M. A. Meyer, History of the City of Gaza (New York, 1907). The latter associating Gaza with Crete, see the latter. Index. r. Minos; the resemblance between the Mycenaen of South Arabia and Cretan inscriptions for all kinds of speculations, ancient (Pliny vi. 157) and modern.

3 Between the central Judaean plateau and the latter lay the Gebalites (Ṣūphēḥālī), a district open equally to Judaean and Philistines alike.

4 Cf. Gaza and Edom against Judah in Amos i. 6, and, for the part played by Damascus, the later vicissitudes under the Nabataeans (Josephus, Ant. xiii. 13, 3). It is difficult to date the alliance of Syria and Philistia against Israel in Isa. ix. 11 sqq. (on the text, see the commentaries).
the coast and, descending from Sidon, took Jaffa, Beth-dagon, Beneberak, Ekron and Timnah (all in the district ascribed to the southern Dan). At Eltekeh (also in Dan) the allies were defeated. Farther south came the turn. Ascalon, Achish, Lishah, Liphah. Judah under Hezekiah suffered severely, and its western cities were transferred to the faithful vassals of Ekron, Ashdod and Gaza. The immediate subsequent events are obscure (see further HEZEKIAH). In the 7th century B.C., Ascalon, Ashdod and Ekron were Assyrian vassals, together with Judah, Moab and Edom—in all, twenty-two kings of the “Hittites” —and the discovery of Assyrian contract-tablets at Gezer (c. 650) may indicate the presence of Assyrian garrisons. But as the Assyrian power declined Egyptian monarchs formed plans of aggrandizement. Herodotus mentions the Syracian invasion and says that the temple of Aphrodite Urania (Astarte) at Ascalon, also the pro-portion of Ashdod to the taken, was immediately after the occupation of Kadytis (7 B.C.) by Necho (i. 105, i. 157 sqq., iii. 5). But the Babylonian Empire followed upon traditional lines and thrust back Egypt, and Nabonidus (553 B.C.) claims his vassals as far as Gaza. The Persians took over the realm of their predecessors, and Gaza grew in importance as a seat of international commerce. Nehemiah speaks not of Philistines, but of Ashdodites (iv. 7), speaking an “Ashdodite” dialect (xii. 24); just as Strabo regards the Jews, the Idumeans, the Gazans and the Ashdodites as four cognate peoples having the common characteristic of combining agriculture with commerce. In southern Philistia at least, Arabian immigration became more pronounced. In the time of Cambyses Arabs were settled at Jenysos south of Gaza (Herod. iii. 5), and when Alexander marched upon Egypt, Gaza with its army of Arabs and Persians offered a strenuous resistance. Recent discoveries near Tell Sandahannah (or Mareshah) have revealed the presence of North Arabian (Edomite) names about the 2nd century B.C.1

On the history of the district see further JEWS; Maccabees; PALESTINE.

3. Philistine Traditions.—The interdependence of the south Palestinian peoples follows from geographical conditions which are unchangeable, and the fuller light thrown upon the last decades of the 8th century B.C. illuminates the more fragmentary evidence elsewhere.2 Hence the two sages of the Philistine Gibbethon by the Israelites (above) obviously have some significance for Judaean history, but the Judaean annals unfortunately afford no help (see ASA). Again, the Aramaean attack upon Israel by Hazael of Damascus leads to the capture of Gath (2 Kings xii. 17), and this, together with the statement that he took “the Philistine” from Jehoahaz of Israel (ibid. xiii. 22, Lucian’s recension), bears upon Judah, but the statements are isolated. Meanwhile later, the Assyrian king Adad-nirari IV. claimed tribute from Edom, Philistia and Beth-Omri (the Israelite kingdom); the curious omission of Judah has suggested that it was then included with the second or third of these (see Jews, § 12). The Philistines naturally had a prominent place in popular tradition, and the story of Isaac and the Philistine Abimelech (Gen. xxvi., cf. xxi. 32) is of great interest for its unbiased representation of intercourse, enmity, alliance and covenant. But it is important to notice that a parallel story (xx.) is without this distinctive Philistine background, and this variation is significant. One account of the Israelite invasion conceived a conquest of earlier giant inhabitants (Anakim) who survived in Gaza, Gath and Ashdod (Joshua xi. 21 seq., contrast xiii. 3), but were driven out by Hebron by Caleb (Joshua xv. 14, cf. Num. xiii. 22, 28). The Philistines themselves are called the remnant of the Anakim (Jer. xviii., ii. the Septuagint), or as Caphthorn replace the earlier Avvim (Deut. ii. 23, see Joshua xiii. 3). Samuel’s great defeat of the Philistines leads to “peace between Israel and the Amorites” (1 Sam. vii. 14); and the migration of the Danites is placed after the Philistine conquests (Judges xvi. 27 seq.), as due to the pressure of Amorites (i. 34). Even in David’s fights with the Philistines in Judah, Jerusalem is Jebusite, neighbouring non-Israelite cities are Hivite or Amorite (Joshua ix. 7, 2 Sam. xxi. 2), and his strange adversaries find a close parallel in the semi-mythical sons of Anak (2 Sam. xxi. 16, 18, 20, 22). This fluctuation, due partly to the different circles in which the biblical narratives took shape, and partly to definite reshaping of the traditions of the past, seriously complicates all attempts to combine the early history of Israel with the external evidence. The history of the Philistine district goes back long before the time of the Pusarati (c. 1200 B.C.), and if the Philistines are Phoenicians (Judges xvi. 27 seq.), as the anachronisms, which those which can be applied to the 12th-11th century do not at once acquire an historical value.3 The references of the time of the Exodus, the Invasion and the “Judges” —whatever chronological scheme be adopted—must be taken in connexion with a careful examination of all the evidence. It is inherently not improbable that a recollection has been preserved of Philistine oppressions in the 11th century, but it is extremely difficult to sketch any adequate sequence of events, and among the conflicting traditions are situations equally applicable to later periods of hostility. Biblical history has presented its own views of the Israelite and Judaeo-Mediterranean era, and its entire literary history is pouring itself from the south (1 Sam. xiii. 17, 18), while the founder of the Judaean dynasty has intimate relations with a Philistine king Achish (or Abimelech, Ps. xxxiv.), or, from another point of view, cleans the district of a prehistoric race of giants. In the stories of Samson and Samuel, the Philistines are located in the maritime plain, whereas, in the oldest trustworthy account of Saul’s rise (apparently shortly before 1000 B.C.) they hold Israel (1 Sam. i. 16, xiii. 3 seq., 7, xiv. 1, 11, 21). But there is no historical continuity between the two situations, and the immediate prelude to the achievements of Saul and Jonathan is lost. The biblical evidence does not favour any continued Philistine domination since the time of Rameses III., who indeed, later in his reign, made an expedition, not against the Pusarati, but into North Syria, and, as appears from the Papyrus Harris, restored Egyptian supremacy over Palestine and Syria. Upon the (incomplete) external evidence and upon a careful criticism of the biblical history of this period, and not upon any promising combination of the two sources, must depend the value of the plausible though broad reconstructions which have been proposed.4

Considerable stress is often laid upon Goliath’s armour of bronze and his iron weapon, but even David himself has helmet, sword and coat-of-mail at his disposal (1 Sam. xviii.), and suits of armour had already been taken from Mesopotamia by Tuthmosis III. Charioms of iron are ascribed to the Canaanites (Joshua xvii. 16, 18, Judges i. 19, iv. 3); but if early references to iron are treated as unhistorical (Gen. iv. 22, Num. xxxii. 22, xxvi. 16, Deut. iv. 20, viii. 9, xix. 5, xxvii. 5, xxviii. 48, xxxii. 25, Joshua vi. 19, 24) Goliath’s iron spear-head must be judged together with the whole narrative in the light of a consistent historical criticism.5

1 The inhabitants of Ascalon besieged by Rameses II are represented as Hittites. For an attempt to treat the pre-Mosaic references as historical, see A. Noordzij, De Philistijnen (Kampen, 1908).

2 See on these, W. M. Müller, Mittel, d. vororientl. Geschichte, p. 39 seq.; G. F. Moore, Enzyk. Bibl., art. “Philistines,” col. 3720 seq., and cf. W. H. Hogg, op. cit. p. 91. For the suggestion that the Philistines “come from” the Canaanites see further, e.g., the testimony of the Sinaitic inscription, see S. A. Cook, Crit. Notes on O. T. History, pp. 43 seq., 127 seq., 131 seq., 136 seq., 144; cf. from another point of view, T. K. Cheyne, Decline and Fall of Kingdom of Judah (1908), pp. xx. seq.

3 The introduction of iron has been proposed by 1000 B.C. (Macalister, Quart. Statein, p. 321 [1905], as against p. 122 [1904]; H. Vincent, Canaan d’apres l’exploration recente, p. 235 seq.). It need hardly be said that the height and might of Goliath must be regarded in the same way as Num. xii. 31: Deut. ii. 11. The arm of the heroic age are giants, as were the ‘Ad and Thamud to the later Arabs.

1 Peters and Thiersch, Painted Tombs in the Necropolis of Marissa (1903).

2 In Judges, the capture of Gezer by Egypt (1 Kings ix. 16) was presumably not only part of some more extensive operations, but their relation to Shishak’s great Palestine campaign is uncertain; see A. Alt, Israel u. Aegypten, pp. 10-13 (Leipzig, 1909). It would be misuse of much from the fact to refer to them, and consider (unjust meaning ambiguous)” of Canaan and Philistia (Bull. Mus. Cairo, i. 98).
4. Conclusions.—The Philistines appear in the Old Testament as a Semitic or at least a thoroughly Semitized people. Their proper names show that before and even during the Persian age their languages differed only dialectically from Hebrew. Among the exceptions must be reckoned Achish (Sept. ἀθήσι), with which has been compared Ikaus, a king of Ekron (1st century a.p.) and the “Keftian” name Akhashu of the XIXth Egyptian Dynasty. Names in -ath (Goliath; Ahuzzath; Gen. xxv. 18), were not restricted to Philistines, and Philo (ibid.) is too obscure to serve as evidence. The religion is not novel. The male god Dagon has his partner Astarte (qq.v.), and Baal-zebub, a famous oracle of Ekron (2 Kings i. 7) finds a parallel in the local “baals” of Palestine.1 Even when the region seems to be completely Hellenized after the Persian age, it is not so certain that Greek culture pervaded all classes (see G. F. Moore, Ency. Bibl. col. 3726), although a certain amount of foreign influence probably made itself felt upon the coast-towns at all times. The use of the term Διόλφος in Maccabean and later writings (cf. the contemptuous hatred of Ben Sira, Ecclusiastus l. 26, and the author of Jubilees xxiv. 30 sqq.) correctly expresses the conditions of the Greek age and the Maccabean wars, and naturally any allusion to the situations of many centuries previously is quite unnecessary. Similarly, the biblical evidence represents the traditions in the form which they had reached in the writer’s time, the true date of which is often uncertain. Antagonism between Philistines and Israelites was not a persistent feature, and, although the former are styled “uncircumcised” (ch. xlv.) (chiefly in the stories in the book of Samuel), the term gained new force when the expulsion of uncircumcised aliens from the sanctuary of Jerusalem was proclaimed in the writings ascribed to Ezekiel (ch. xlv.).2

In fact the question arises whether the history of the Philistines is not that of a territorial designation, rather than that of the lineal descendants of the Purasati, who, if one of the peoples who took part in the events of the XXth Dynasty, may well have bequeathed their name. The Mediterranean coast-land was always exposed to incursions of aliens, and when Carthaginians appear as royal and temple guards at Jerusalem (2 Kings xi. 4), it is sufficient to recall old Greek traditions of a Carian sea-power and relations between Philista and Greek lands.3 Even the presence of Carthaginians in the time of Psammetichus I. may possibly be suggested, and when these phenomena are noteworthy it is also closely associated with a Jewish colony (viz. Taanahes, Jer. xliii. seq.). Although the Purasati appear after the 15th-14th centuries, now illuminated by the Amarna tablets, their own history is perhaps earlier.4 But there is no reason at present to believe that their entrance caused any break in the archaeological history. The apparently “Aegyan” influence which enters into the general “Amarna” period seems to begin before the age of the Amarna tablets (at Lachish), and it passes gradually into later phases contemporary with the

1 See further, F. Schwalz, Zitt. Wissens. Theol., xxiv. 105-108. A few Hebrew words have been regarded as Philistine loan-words, so notably pilagess, “concubine” (παλασα, παλασοι, Lat. pelles), and seren (σαρωσ) the title applied to the five lords of the Philistine confederacy by the Amarna tablets. It may have been applied metaphorically like the Arab, gebi (W. R. Smith, Philo, 56). The other hand, a common origin in Asia Minor is also possible for these words.2

In the prophetic writings the Philistines are denounced with (Ammon, Moab and Edom) for their vengeance upon Judah (Exek. xxv. 15-17). With Tyre and Sidon they are condemned for plundering Judah, and for kidnapping its children to sell to the Greek merchants (Ezek. xxv. 1 sqq., ch. xxvi. 1 sqq.) and threatened with a foe from the north (Jer. xxxvii. 20; Isa. xiv. 29-31; see ZEPHANIAH), as also is Phoenicia. (Jer. xlvi. 2-7) upon whom they depend (cf. Zech. iii. 3-9). Judah is promised retributions (Zeph. iii. 8, Obad. 16), and a remnant of the Philistines may become worshippers of Yahweh (Zech. ix. 7). The historical background of these passages are disputed.

5 This is suggested by the recent discovery at Phaestos in Crete of a disk with evidence for a native script; see A. J. Evans, Scripta Minoa (Oxford, 1909), pp. 22 sqq.; E. Meyer, Säntnerberichte of the Berlin Academy for the 21st of October 1909.

Israelite monarchy. There is a fairly continuous intercourse with external culture (Cyproite, early and late Greek), and, if Gath be identified with Tel es-Sāh, Bliss and Macalister, who excavated it, found no trace of any interruption in its history. Only at Gezer—perhaps Philistine, 2 Sam. v. 25—has there been found evidence for a strange race with several distinctive features. It is possible that we have here discovered containing bodies outstretched (not contracted); the deposits were of an unusually fine character and comprised silex, alabaster and even iron. The culture appears to find Carian and Lydian parallels, and has been ascribed provisionally to the 13th-10th centuries. So far, however, of the cities lying within or immediately exposed to Philistine influence, the discoveries at Gezer are unique.6

According to the biblical traditions the Philistines are the remnant of Capthor (Jer. xlvii. 4, Amos ix. 7), and the Captörhm brought not the original Avva from Gaza and district, as the Horites and Rephaim were displaced by Edom and Ammon (Deut. ii. 23). These Captörhm, together with Ludim (Lydians) and other petty peoples, apparently of the Delta, are once reckoned to Egypt (Gen. x. 14).6 By Captörhm the Septuagint has sometimes understood Cappadocia, which indeed may be valid for its age, but the name is to be identified with the Egyptian Καπτόρ, which in later Ptolemaic times seems to mean Phoenicia, although Kefiliu had had another connotation. The Cherethites, associated with the Philistine district (1 Sam. xxxiv. 14, 16, Ezek. xxxv. 16, Zeph. ii. 5 seq.), are sometimes recognized by the Septuagint as Cretans, and with the Peletheres (often taken to be a rhyming form of Philistus), they form part of the royal body-guard of Judean kings (2 Sam. viii. 18, xv. 7, xvi. 7-11, Kings i. 38; 44 in 2 Sam. xx. 23 the Hebrew text has Cartes). However adequate these identifications may seem, the persistence of an independent clan or tribe of Cherethites-Cretans to the close of the 7th century would imply an unbroken chain of nearly six hundred years, unless, as is inherently more probable, later immigrations had occurred within the interval. But upon the ethnological relations either of the south Palestinian coast or of the Delta it would be unsafe to dogmatize. So far as can be ascertained, then, the first mention of the Philistines belongs to an age of disturbance and change in connexion with movements in Asia Minor. Archaeological evidence for their influence has indeed been adduced,7 but it is certain to have some ancient, rather than at all ages, a link by land from North Syria and Asia Minor. The influences, whether from the Levant or from the north, were not confined to the age of Rameses III. alone, and the biblical evidence, especially, while possibly preserving some recollection of the invasion of the Purasati, is in every case late and may be shaped by later historical vicissitudes. It is impossible that Palestine should have remained untouched by the external movements in connexion with the Delta, the Levant and Asia Minor, and it is possible that the course of internal history in the age immediately before and after 1000 B.C. ran upon lines different from the detailed popular religious traditions which the biblical historians have employed. (See further PERSIA: History.)

(S. A. C.)

PHILISTUS, Greek historian of Sicily, was born at Syracuse about the beginning of the Peloponnesian War (432 B.C.). He was a faithful supporter of the elder Dionysius, and commander

7 This may be a second meaning, "written from specially intimate acquaintance with the (later?) Egyptian geography." (J. Skinner, Genesis, p. 214.)

8 See D. G. Hogarth, Ionia and the East, pp. 28 sqq. (1909); Evans, Scripta Minoa, pp. 77 sqq.
of the citadel. In 386 he excited the jealousy of the tyrant by secretly marrying his niece, and was sent into banishment.

He settled at Thurii, but afterwards returned to Agrigentum, where he remained until the death of Dionysius (366). He was then recalled by the younger Dionysius, whom he persuaded to disman Plato and Dion. When Dion set sail from Zacynthus with the object of liberating Syracuse from the tyrants, Philistus was entrusted with the command of the fleet, but he was defeated and put to death (356). During his stay at Agrin, Philistus occupied himself with the composition of his Σκελετα, a history of Sicily in eleven books. The first part (bk. i.-vii.) comprised the history of the island from the earliest times to the capture of Agrigentum by the Carthaginians (406); the second, the history of the elder and the younger Dionysius down to (366). From this point the work was carried on by Philistus's fellow-countryman Athanas. Cicero (ad. Q. Fr. ii. 13), who had a high opinion of his work, calls him the minuscule Thucyides (πολυσιλον Θυκυδίδεω). He was admitted by the Alexandrian critics into the canon of historiographers, and his work was highly valued by Alexander the Great.

PHAIIUR, a town of British India, in Jullundur district, Punjab, on the north bank of the river Suslej, 8 m. N. of Ludhiana. Pop. (1901), 6896. Founded by the Mogul emperor Shah Jahan, it was long important as commanding the crossing of the Sutlej. At the Mutiny in 1857 the fort contained the siege train, which was sent safely to Delhi; but the sepoys regiment in the cantonment were afterwards mutinied and escaped. The fort is now occupied by the police training school and the central bureau of the criminal identification department.

PHILLIMORE, SIR ROBERT JOSEPH (1810-1885). English judge, third son of a well-known ecclesiastical lawyer, Dr Joseph Phillimore, was born at Whitehall on the 6th of November 1810. Educated at Westminster and Christ Church, Oxford, where he made a long friendship with W. E. Gladstone began, his first appointment was to a clerkship in the board of control, where he remained from 1832 to 1835. Admitted as an advocate at Doctors' Commons in 1836, he was called to the bar at the Middle Temple in 1841, and rose very rapidly in his profession. He was engaged as counsel in almost every case of importance that came before the admiralty, probate or divorce courts, and became successively master of faculties, commissary of the deanes and chapters of St Paul's and Westminster, official of the archdeaconries of Middlesex and London, and chancellor of the dioceses of Chichester and Salisbury. In 1853 he entered parliament as member for Tavistock. A moderate in politics, his energies were devoted to non-party measures, and in 1854 he introduced the bill for allowing viva voce evidence in the ecclesiastical courts. He sat for Tavistock until 1857, when he offered himself as a candidate for Coventry, but was defeated. He was appointed judge of the Cinque Ports in 1855, Queen's Counsel in 1858, and advocate-general in admiralty in 1862, and succeeded Dr Stephen Lushington (1782-1873) as judge of the court of arches five years later. Here his care, patience and courtesy, combined with unusual lucidity of expression, won general respect. In 1875, in accordance with the Public Worship Regulation Act, he resigned, and was succeeded by Lord Penzance. When the Judicature Act came into force the powers of the admiralty court were transferred to the High Court of Justice, and Sir Robert Phillimore was therefore the last judge of the admiralty court of the lord high admiral of England. He continued to sit as judge for the new admiralty, probate and divorce division until 1883, when he resigned. He wrote Ecclesiastical Law of the Church of England, a book which still holds its ground, Commentaries on International Law, and a translation of Lessing's Laocoon. He married, in 1844, Charlotte Anne, daughter of John Denison of Ossington Hall, Newark. He was knighted in 1862, and created a baronet in 1881. He died at Shiplake, near Henley-on-Thames, on the 4th of February 1885. His eldest son, Sir Walter G. F. Phillimore (b. 1845), also distinguished as an authority on admiralty law, became in 1897 a judge of the high court.

PHILLIP, JOHN (1817-1867). Scottish painter, was born at Aberdeen, Scotland, on the 16th of April 1817. His father, an old soldier, was in humble circumstances, and the son became an errand-boy to a tinsmith, and was then apprenticed to a painter and glazer. Having received some technical instruction from a local artist named William Mercer, he began, at the age of fifteen, to paint portraits. In 1834 he made a very brief visit to London. About this time he became assistant to James Forbes, an Aberdeen portrait-painter. He had already gained a valuable patron. Having been sent to repair a window in the church of St Mary, Longmarket, a work of art in the house attracted the attention of their owner. Gordon brought the young artist under the notice of Lord Panmure, who, in 1836 sent him to London, promising to bear the cost of his art education. At first Philipp was placed under T. M. Joy, but he soon entered the schools of the Royal Academy. In 1839 he figured for the first time in the royal academy exhibition with a portrait and a landscape, and in the following year he was represented by a more ambitious figure-picture of "Tasso in Disguise relating his Persecutions to his Sister." For the next ten years he supported himself mainly by portraiture and by paintings of subjects of national incident, such as "Presbyterian Caricature," "Baptism in Scotland," and "The Scotsman." His productions at this period, as well as his earlier subject-pictures, are reminiscent of the practice and method of Wilkie and the Scottish genre-painters of his time. In 1851 his health showed signs of delicacy, and he went to Spain in search of a warmer climate. He was brought face to face for the first time with the brilliant sunshine and the splendid colour of the south, and it was in coping with these that he first manifested his artistic individuality and finally displayed his full powers. In the "Letter-writer of Seville" (1854), commissioned by Queen Victoria at the suggestion of Sir Edwin Landseer, the artist is struggling with new difficulties in the portrayal of unattained splendours of colour and light. In 1857 Philip was elected an associate of the Royal Academy, and in 1859 a full member. In 1853 and in 1866 further visits to Spain were made, and in each case the painter returned with fresh materials to be embodied with increasing power and subtlety in the long series of works which won for him the title of "Spanish Philip." His highest point of execution is probably reached in "La Gloria" (1864) and a smaller single-figure painting of the same period entitled "El Cigarillo." These Spanish subjects were varied in 1866 by a rendering of the marriage of the princess royal with the crown prince of Prussia, executed by command of the queen, and in 1865 by a picture of the House of Commons. During his last visit to Spain Philip occupied himself in a careful study of the art of Velasquez, and the copies which he made fetched large prices after his death, examples having been secured by the royal and the royal Scottish academies. The year before his death he visited Italy and devoted attention to the works of Titian. The results of this study of the old masters are visible in such works as "La Loteria Nacional," "left uncompleted at his death. During this period he resided much in the Highlands, and seemed to be returning to his first love for Scottish subjects, painting several national scenes, and planning others that were never completed. He died in London on the 27th of February 1867.

His works were collected in the International Exhibition of 1873, and many of them are engraved by T. Oldham Barlow. In addition to the paintings already specified the following are among the more important: "Life among the Gipsies of Seville" (1883); "El Paseo" (1835); "Collection of the Offertory in a Scotch Kirk" (1865); A Gipsy Water-carter in Seville (1845); The Prayer of Faith shall save the Sick (1856); The Dying Contrabandist (1866); The Prison Window (1857); A Huff (1859); Early Career of Murillo (1860); A Chat round the Braser (1866).

PHILLIPS, ADELAIDE (1833-1882), American contralto singer, was born at Stratford-on-Avon, England, her family emigrating to America in 1840. Her mother taught dancing,
PHILLIPS, E.—PHILLIPS, S.

and Adelaide began a career on the Boston stage at ten years old. But in 1850 her talent for singing became evident, and through Jenny Lind and others she was sent to London and to Italy to study. In 1855 she returned to America an accomplished vocalist; and for many years she was the leading American contralto, equally successful in oratorio and on the concert platform. She died at Carlisle on the 3rd of October 1886.

PHILLIPS, EDWARD (1630-1690), English author, son of Edward Phillips of the crown office in chancery, and his wife Anne, only sister of John Milton, the poet, was born in August 1630 in the Strand, London. His father died in 1631, and Anne Phillips eventually married her husband's successor in the crown office, Thomas Agar. Edward Phillips and his younger brother, John, were educated by Milton. Edward entered Magdalen Hall, Oxford, in November 1650, but left the university in 1651 to be a bookseller's clerk in London. Although he entirely differed from Milton in his religious and political views, and seems, to judge from the free character of his Mysteries of Love and Eloquence (1658), to have undergone a certain revision from his Puritan upbringing, he remained on affectionate terms with his uncle to the end. He was tutor to the son of John Evelyn, the diarist, from 1653 to 1672 at Sayes Court, near Deptford, and in 1677-1679 in the family of Henry Bennet, earl of Arlington. The date of his death is unknown, but his last book is dated 1696.

His most important work is Theoriam postearum (1673), a list of the poets of the countries, but especially of the English poets, with short critical notes and a preface Discourse of the Poets and Poetry, which has usually been traced to Milton's hand. He also wrote A New World in Words, or a General Dictionary (1678), which went through many editions; a new edition of Baker's Chronicle, of which the section on the period from 1650 to 1658 was written by himself from the royalist standpoint; a supplement (1676) to John Speed's Theatre of Great Britain; and 1664 Enchiridion linguae latinae, said to have been taken chiefly from notes prepared by Milton. Aubrey states that all Milton's papers came into Phillips's hands, and in 1694 he published a translation of more valued texts.

His brother, John Phillips (1631-1706), in 1652 published a Latin reply to the anonymous attack on Milton entitled Pro Rege et populo anglicano. He appears to have acted as unofficial secretary to Milton, but, disappointed of regular political employment, and chafing against the discipline he was under, he published in 1653 a bitter attack on Puritanism entitled Satyr against Hypocrizes (1655). In 1656 he was summoned before the privy council for his share in a book of licentious poems, Sportive Wit, which was suppressed by the authorities but almost immediately replaced by a similar collection, Wit and Drollery. In Montelion (1660) he ridiculed the astrological almanacs of William Lilly. Two other skits of this name, in 1661 and 1663, also full of course royalist wit, were probably by another hand. In 1678 he supported the agitation of Titus Oates, writing on his behalf, says Wood, "many lies and villanies." Dr Oates's Narrative of the Popish Plot indicated was the first of these tracts. He began a monthly historical review in 1668 entitled Modern History or a Monthly Account of all considerable Occurrences, Civil, Ecclesiastical and Military, followed in 1690 by The Present State of Europe, or a Historical and Political Mercury, which was supplemented by a preliminary volume giving a history of events from 1668. He executed many translations from the French, and a version (1687) of Don Quixote.

An extended, but by no means friendly, account of the brothers is given by Wood, Athen. eunx. (ed. Bliss, iv. 754 seq.), where a long list of their works is dealt with. This formed the basis of William Godwin's Lives of Edward and John Phillips (1819), with which is reprinted Edward Phillips's Life of John Milton.

PHILLIPS, JOHN (1600-1674), English geologist, was born on the 27th of October 1600 at Marden in Wiltshire. His father belonged to an old Welsh family, and settled in England as an officer of excise and married the sister of William Marbury, the "Father of English Geology." Both parents dying when he was a child, Phillips came under the charge of his uncle; and after being educated at various schools, he accompanied Smith on his wanderings in connexion with his geological maps. In the spring of 1824 Smith went to York to deliver a course of lectures on geology, and his nephew accompanied him. Phillips accepted engagements in the principal Yorkshire towns to arrange their museums and give courses of lectures on the collections contained therein. York became his residence, where he obtained, in 1825, the situation of keeper of the Yorkshire museum and of the York Philosophical Society. Here he extended his operations to towns beyond the county; and in 1831 he included University College, London, in the sphere of his activity. In that year the British Association for the Advancement of Science was founded at York, and Phillips was one of the active minds who organized its machinery. He became in 1832 the first assistant secretary, a post which he held until 1850. In 1834 he accepted the professorship of geology at King's College, London, but retained his post at York. In 1834 he was elected F.R.S.; in later years he received hon. degrees of LL.D. from Dublin and Cambridge, and D.C.L. from Oxford; while in 1845 he was awarded the Wollaston Medal by the Geological Society of London. In 1840 he resigned his charge of the York museum and was appointed on the staff of the geological survey of Great Britain under De la Beche. He spent some time in studying the Palaeozoic fossils of Devon, Cornwall and West Somerset, of which he published a descriptive memoir (1841); and he made a detailed survey of the region of the Malvern Hills, of which he prepared the elaborate account that appears in vol. ii. of the Memoirs of the Survey (1848). In 1844 he became professor of geology in the university of Dublin. Nine years later, on the death of H. E. Strickland, who had acted as substitute for Dean Buckland in the readership of geology in the university of Oxford, Phillips succeeded to the post of deputy, and at the dean's death in 1856 became himself reader, a post which he held to the time of his death. During his residence in Oxford he took a leading part in the foundation and arrangement of the new museum erected in 1859 (see his Notices of Rocks and Fossils in the University Museum, 1863; and The Oxford Museum, by H. W. Acland and J. Ruskin, 1859; reprinted with additions 1893). Phillips was also keeper of the Ashmolean museum from 1854-1870. In 1859-1860 he was president of the Geological Society of London, and in 1865 president of the British Association. He dined at All Souls College on the 23rd of April 1874, but on leaving he slipped and fell down a flight of stone stairs, and died on the following day.

From the time he wrote his first paper "On the Direction of the Diggings in a Coalpit" (1822), events in the science he loved and practised throughout his life, Phillips continued a constant contributor to the literature of science. The pages of the Philosophical Magazine, the Journal of the Geological Society, the Geological Magazine and other publications were the scene of numerous separate works, which were of great benefit in extending a sound knowledge of geology. Among these may be specially mentioned: Illustrations of the Geology of Yorkshire (in two parts, 1829 and 1836; 2nd ed. of pt. i. in 1855, 3rd ed. edited by R. Etheridge, in 1875); A Treatise on Geology (1837-1839); Memoirs of William Smith (1844); The Rivers, Mountains and Sea-Coast of Yorkshire (1855); Manual of Geology, Practical and Theoretical (1855); Life on the Earth: its Origin and Succession (1860); Vestiges (1869); Geology of Oxford and the Valley of the Thames (1871). To these should be added his Monograph of British Belonidae (1864), formed for the Palaeontographical Society, and his geological map of the British Isles (1847).

See Biographical Memoir, with portrait, in Geol. Mag. (July 1870).

PHILLIPS, SAMUEL (1814-1854), English journalist, the son of a Jewish tradesman in London, was born on the 28th of December 1814. He was educated at University College, London, and then at Göttingen. Having renounced the Jewish faith, he returned to England and entered Sidney Sussex College, Cambridge, with the design of taking orders. His father's death, however, prevented this, and in 1841 he took to literary work. He wrote a novel, Caleb Steelkey (1853), and other tales, and about 1845 began a connexion with The Times as literary critic. In the following year he purchased the Society of Antiquaries, and edited it for a year. Two volumes of his Essays from The Times appeared in 1852 and 1854. Phillips took an active part in the formation of the Crystal Palace Company, and wrote their descriptive guides. In 1852 the university of Göttingen
PHILLIPS, S.—PHILLIPS, WENDELL

407

conferred upon him the honorary degree of LL.D. He died at Brighton on the 14th of October 1854.

PHILLIPS, STEPHEN (1770-1823), British poet and dramatist, was born on 17 July 1770 at Longdon near Oxford, the son of the Rev. Stephen Phillips, precentor of Peterborough Cathedral. He was educated at Stratford and Peterborough Grammar Schools, and entered Queen's College, Cambridge; but during his first term at Cambridge, when F. R. Benson's dramatic company visited the town, he joined it, and for six years played various small parts. In 1800 a slender volume of verse was published at Oxford with the title Primavera, which contained contributions by him and by his cousin Laurence Binyon and others. In 1804 he published Eremus, a long poem of loose structure in blank verse of a philosophical complexion. In 1805 appeared Christ in Hades, forming with a few other short pieces one of the slim paper-covered volumes of Elkin Mathews's "Shilling Garland." This poem arrested the attention of watchful critics of poetry, and when it was followed by a collection of Poems in 1807 the writer's position as a new poet of exceptional gifts was generally recognized. This volume contained a new edition of "Christ in Hades," together with "Marpessa," "The Woman with the Dead Soul," "The Wife," and shorter pieces, including the fine lines "To Milton, Blind." The volume won the prize of £100 offered by the Academy newspaper for the best new book of its year, ran through half a dozen editions in two years, and established Mr. Phillips's rank as poet, which was sustained by the publication in the Nineteenth Century in 1808 of his poem "Endymion." George Alexander, the actor-manager, moved perhaps by a certain glamour among the critics for a literary drama, then commissioned Mr Phillips to write him a play, the result being Paolo and Francesca (1800), a drama founded on Dante's famous episode. Encouraged by the great success of the drama in its literary form, Mr Alexander produced the piece at the St James's Theatre in the course of 1801. In the meantime, Mr Phillips's next play, Iero: a Tragedy, had been produced by Beerbohm Tree on the 31st of October 1800, and was published as a book in 1801; Ulysses, also produced by Beerbohm Tree, was published in 1802; The Sin of Daniel, a drama on the story of David and Bathsheba, translated into the times and terms of Cromwellian England, was published in 1804; and Nero, produced by Beerbohm Tree, was published in 1806. In these plays the poet's avowed aim was, instead of attempting to revive the method of Shakespeare and the Elizabethans, to revitalize the method of Greek drama. Paolo and Francesca (which admitted certainly one scene on an Elizabethan model) was the most successful, the subject being best adapted to the lyrical cast of Mr Phillips's poetical temperament; but all contained fine poetry, skilfully stage-managed by a writer who had practical experience of stage craft.

For bibliography up to July 1903, see English Illustrated Magazine new series, vol. xxix. p. 442.

PHILLIPS, THOMAS (1770-1843), English portrait and subject painter, was born at Dudley in Warwickshire on the 18th of October 1770. Having acquired the art of glass-painting at Birmingham he visited London in 1790 with an introduction to Benjamin West, who found him employment on the windows in St George's Chapel, Windsor Castle. In 1792 Phillips painted the portrait of the Duke of Wellington, and in the next two years he exhibited the "Death of Talbot, Earl of Shrewsbury, at the Battle of Castillon," "Ruth and Naomi," "Elijah restoring the Widow's Son," "Cupid disarmed by Euphrosyne," and other pictures. After 1796, however, he mainly confined himself to portrait-painting. It was not long before he became the chosen painter of men of genius and talent, notwithstanding the rivalry of Hoppner, Owen, Jackson and Lawrence; and he left behind portraits of nearly all the illustrious characters of his day. In 1804 he was elected associate and in 1808 member of the Royal Academy. In 1824 Phillips succeeded Fuseli as professor of painting to the Royal Academy, in which capacity he reigned for over twenty years, and he published ten Lectures on the History and Principles of Painting, which were published in 1833. He died on the 20th of April 1845.

PHILLIPS, WENDELL (1811-1884), American orator and reformer, was born in Boston on the 29th of November 1811. His father, John Phillips (1770-1823), a man of wealth and influence, graduated at Harvard College in 1788, and became successively "town advocate and public prosecutor," and in 1822 first mayor of Boston, then recently made into a city. Wendell Phillips himself attended the public Latin school, entered Harvard College before he was sixteen, and graduated in 1831 in the same class with the historian John Lothrop Motley. He graduated at the Harvard law school in 1834, and was admitted to the bar in Boston. He soon came under the influence of the anti-slavery movement, witnessing in 1835 the mobbing, in Boston, of William Lloyd Garrison. On the 8th of December 1837 a meeting was held at Faneuil Hall to express the sentiments of the people on the murder of Elijah P. Lovejoy, at Alton, Illinois, for defending his press from a pro-slavery mob. In the course of the meeting a speech was made in opposition to its general current by James T. Austin (1874-1879), attorney-general of the state, who said that Lovejoy had died "as the fool dieth," and compared his murderers to the men who threw the tea into Boston harbour just before the War of Independence. The speech seemed likely to divide the audience, when Wendell Phillips took the platform. "When I heard," he said, "the gentleman lay down principles which placed the murderers of Alton side by side with Otis and Hancock, with Quincy and Adams, I thought these pictured lips (pointing to their portraits) would have broken into voice to rebuke the recreant American, the slanderer of the dead." This appeal not merely determined the sentiment of the meeting, it gave Wendell Phillips his first fame and determined his career. Although loving his profession, and this especially for the opening it gave in the direction of public life, he practically stepped outside the sphere dearest to young Americans, and lived henceforth the life of an agitator, or, like his father, that of a "public prosecutor." Accepting unhesitatingly the leadership of Garrison, and becoming like him gradually a disunionist, he lived essentially a platform life, interested in a variety of subjects, but first and chiefly an abolitionist. In 1865, however, after the Civil War, he broke with Garrison over the question of discontinuing the Anti-Slavery Society, and from that date until the society was disbanded in 1870 he, instead of Garrison, was its president. He was not, moreover, like his great leader, a non-resistant, nor was he, on the other hand, like John Brown, borne on by irresistible necessity to overt action. Nor did he find, like his fellow-worker, Theodore Parker, the leisure to keep up his scholarship and lead in part the life of a student. Early study and travel had indeed furnished him with abundant material for rhetorical illustration; and he was also a great reader of newspapers, but he used to say that he knew in his whole life but one thing thoroughly, namely, the history of the English Civil War, and there were few occasions when he could not draw from it the needed illustration. His style of eloquence was direct and brilliant, but eminently self-controlled. He often surprised his hearers by the quietness of his beginnings, and these were very often the speeches which turned out most brilliant and most irresistible were the close. He may be said to have introduced the direct and colloquial manner upon the American public platform, as distinct from the highly elaborated and often ornate style which had been established by Edward Everett; nor has there ever been a reversion since his day to the more artificial method. He was capable at times, nevertheless, of highly sonorous periods with superb climaxes; yet his favourite style was the conversational. His logic, while never obtruded, was rarely at fault; but he loved the flash of the rapier, and
PHILLIPS, William (1775–1838), British mineralogist and geologist, son of James Phillips, printer and bookseller in London, was born on the 10th of May 1775. He early became interested in mineralogy and geology, and was one of the founders of the Geological Society of London (1807). His *Outlines of Mineralogy and Geology* (1815) and *Elementary Introduction to the Knowledge of Mineralogy* (1816) became standard textbooks. His digest of English geology, *A selection of Facts from the Best Authorities, arranged so as to form an Outline of the Geology of England and Wales* (1818), formed the foundation of the larger work undertaken by Phillips in conjunction with W. D. Conybeare, of which only the first part was published, entitled *Outlines of the Geology of England and Wales* (1822). This volume made an era in geological exposition, and it was remarkable for the clearness, observation, of judicious compilation, of succinct description and of luminous arrangement it has been of the utmost service in the development of geology in Britain. In this work Phillips reprinted his admirable description of the chalk cliffs of Dover and other parts of East Kent, published in 1815 in *Trans. Geol. Soc.* vol. v. Phillips was a member of the Society of Friends. He was elected a Fellow of the Royal Society in 1827. He died on the 2nd of April 1828.

His brother, Richard Phillips (1776–1851), was distinguished as a chemist, and became F.R.S. in 1822. He was an assistant professor of chemistry at the University of Edinburgh (afterwards Practical Geology), then situated in Craig’s Court (1839). He was the author of papers published in the *Annals of Philosophy and Philosophical Magazine*. In 1796 the two brothers, together with William Allen and Luke Howard, took part in forming the Askean Society.

PHILLIPS was never happier than when he had to face down a mob and utterly foil it by sheer superiority in fencing. The two volumes of his speeches, as edited by James Redpath, were fortunately made from verbatim reports, and they wisely enclose in parentheses those indications of favour or dissent from the audience which transformed so many of his speeches into exhibitions of gladiatorial skill. He was a tribune of the people, associated unfailingly not merely with the unpopular but with the unpolished; always carrying about him not merely a certain Roman look, but a patrician air. After slavery had fallen Phillips associated himself freely with reformers occupied in other paths, herein separating himself from the other patricians of the movement, Edmund Quincy, who always frankly said that after slavery was abolished there was nothing else worth fighting for. Among other things, Phillips contended, during his later years, for prohibition, woman sufrage and various penal and administrative reforms. He was not always the best judge of character, and was sometimes allied in these movements with men who were little more than demagogues. But the proof he gave by his transfer of energies that the work of reform was never quite finished—this was something of peculiar value, and worth the risk of some indiscretions. The life of a reformer did not in itself make him thoroughly happy; he chafed more and more under its fatigues, and he always felt that his natural place would have been among senators or ambassadors; but he belonged essentially to the heroic type, and it may well have been of him that Emerson was thinking when he wrote those fine words: “What forests of laurel we bring and the tears of mankind to him who stands firm against the opinion of his contemporaries.”

His domestic life was most happy, though his wife was a confirmed invalid, seldom quitting her room. She was a woman of heroic nature and very strong convictions. Her husband used to say that she first made him an abolitionist. They had no children, but adopted an orphaned daughter of Mrs Eliza Gurnart, a friend, and this young girl (afterwards the wife of George W. Smalley), brought much light and joy into the household. Their worldly circumstances were easy, though they were always ready to impoverish themselves for the sake of others. Wendell Phillips died in Boston on the 2nd of February 1884.

PHILLIPSBURG, a town of Warren county, New Jersey, U.S.A., on the Delaware river, opposite Easton, Pennsylvania, and about 51 m. N.N.W. of Trenton, N.J. *Pop.* (1900) 10,052, of whom 990 were foreign-born; (1910 U.S. census) 13,963. Served by the Central of New Jersey and other railways, the town is situated in the river bottom and on a bluff which commands beautiful views. The river is spanned here by several bridges. The town has railway shops and various manufactures. In 1905 the value of the factory products was $6,084,173 (45.8% more than in 1900). Phillipsburg was settled about 1750. It was only a straggling village when the Morris Banking and Canal Company was chartered in 1824, but its growth was accelerated by the canal (no longer used), by the establishment in 1848 of an iron furnace, and by the completion of the Central Railroad of New Jersey to this point in 1825; the town was incorporated in 1861.

PHILLIPSITE, a mineral of the zeolite group; a hydrated potassium, calcium and aluminium silicate, approximating to (K₂, Ca)_4(H₂O)₂(SiO₄)₃. It varies somewhat in composition, and a variety ("pseudophillipsite") containing rather less silica has the formula (K₂, Ca)₂Al₂Si₂O₇·H₂O. Crystals are monoclinal, but only complex cruciform twins are known, these being exactly like twins of harmotome (q.v.). Crystals of phillipsite are, however, usually smaller and more transparent and glassy than those of harmotome. Spherical groups with a radially fibrous structure and bristled with crystals on the surface are not uncommon. The hardness is 4½, and the specific gravity 2·2. The species was established by A. Lévy in 1825 and named after William Phillips. French authors use the name christianite (after Christian VIII of Denmark), given by A. Des Cloizeaux in 1847.

Phillipite is a mineral of secondary origin, and occurs with other zeolites in the amygdaolid cavities of basic volcanic rocks: e.g. in the basalts of the Giant’s Causeway in County Antrim, and near Melbourne in Victoria; and in lenticular near Rome. Small crystals of recent formation have been observed in the masonry of the hot baths at Plombières and Bourbons-les-Bains, in France. Minute spherical aggregates embedded in red clay were dredged by the "Challenger" from the bottom of the Central Pacific, where they had been formed by the decomposition of lava.

(F. S.)

PHILLIPPTS, Henry (1778–1869), English bishop, was born at Bridgrater on the 6th of May 1778, and was educated at Glasgow and Oxford Colleges. He became a fellow of Magdalen College, Oxford, in 1795, took orders in 1802, and was select university preacher in 1804. In 1805 he received the living of Stanton-le-Street, Durham, and in addition was appointed to Bishop Middleham, Durham, in the succeeding year. For twenty years he was chaplain to Shute Barrington, bishop of Durham. He was appointed vicar of Gateshead in 1808, prebendary of Durham in 1809, and vicar of St Margaret, Durham, in 1810. After holding the rich living of Stanhope, Durham, from 1820, and the deanery of Chester from 1828, he was consecrated bishop of Exeter in 1821, holding with the see a residential canonry at Durham. His diocese was largely composed of counties which included numerous parishes and manors, and in no way connected with the Roman Catholic controversy with Charles Butler (1750–1832). He was an energetic supporter of the Tory party, even when it acted contrary to his views in passing the Roman Catholic Emancipation Act of 1829. He died on the 18th of September 1869. "Henry of Exeter," as he was commonly called, was one of the most striking figures in the English Church of the 18th century. His intellect was strong rather than broad, his position being that of the traditional High Churchman, with little sympathy either with the Evangelicals or with the Tractarians. On the one hand the famous Gorham judgment was the outcome of his influence. A disciple of St. John Henry Newman, he wrote a classic in the person of George Cornelius Gorham (1787–1857), who had openly disavowed his belief in baptismal regeneration; on the other he denounced the equally famous Tract XC. In his episcopal charge of 1843. As bishop he was a strict disciplinarian, and...
PHILO, Jewish Hellenist, and author of an epic poem in Greek hexameters on the history of Jerusalem. Alexander Polyhistor (c. 105-35 B.C.) quotes several passages of the poem, and is the source of the extracts in Eusebius (Praeaepturatio evangelica, ix. 26, 24, 37). This is probably the Philo who is mentioned by Clemens Alexandrinus (Strom. i. 21, 141) and by Josephus (Contra Apionem, i. 23), who calls him "the elder."

See M. Philippi's work on the Jewish poets Ezechiel and Philo (Berlin, 1839, 1840).

PHILO, often called PHILO JUDAÆUS, Jewish philosopher appears to have spent his whole life at Alexandria, where he was probably born c. 20-10 B.C. His father Alexander was alabarch or arabarch (that is, probably, chief farmer of taxes on the Arabic side of the Nile), from which it may be concluded that the family was influential and wealthy (Jos. Ant. xviii. 8, 1). Jerome's statement (De vir. ill. 11) that he was of priestly race is confirmed by no older authority. The only event of his life which can be actually dated belongs to A.D. 40, when Philo, then a man of advanced years, went from Alexandria to Rome, at the head of a Jewish embassy, to persuade the emperor Gaius to abstain from claiming divine honour of the Jews. Of this embassy Philo has left a full and vivid account (De legatione ad Gaium). Various fathers and theologians of the Church state that in the time of Claudius he met St Peter in Rome; 1 but this legend has no historic value, and probably arose because the book De vita contemplativa, ascribed to Philo, in which Eusebius already recognized a glorification of Christian monasticism, seemed to indicate a disposition towards Christianity.

1 Though we know so little of Philo's own life, his numerous extant writings give the fullest information as to his views of the universe and of life, and his religious and scientific aims, and so enable us adequately to estimate his position and importance in the history of thought. He is quite the most important representative of Hellenistic Judaism, and his writings give us the clearest view of what this development of Judaism was and aimed at. The development of Judaism in the Diaspora (q.e.) differed in important points from that in Palestine, where, since the successful opposition of the Maccabees to the Hellenization which Antiochus Epiphanes had sought to carry through by force, the attitude of the nation to Greek culture had been essentially negative. In the Diaspora, on the other hand, the Jews had been deeply influenced by the Greeks; they soon more or less forgot their Semitic mother-tongue, and with the language of Hellen they appropriated much of Hellenic culture. They were deep imprinted by that irresistible force which was blending all races and nations into one great cosmopolitan unity, and so the Jews too on their dispersion became in speech and nationality Greeks, or rather "Hellenists." 2 Now the distinguishing character of Hellenism is not the absolute disappearance of the Oriental civilizations before that of Greece but the combination of the two with a preponderance of the Greek element. So it was with the Jews, but in their case the old religion had much more persistence than in other Hellenistic circles, though in other respects they too yielded to the superior force of Greek civilization. This we must hold to have been the case not only in Alexandria but throughout the diaspora from the commencement of the Hellenistic era to the latter part of the 3rd century A.D. It was only after ancient civilization gave way before the barbarian immigrations and the rising force of Christianity that rabbinism became supreme even among the Jews of the diaspora. This Hellenistic-Judaic phase of culture is sometimes called "Alexandrian," and the expression is justifiable if it only means that in Alexandria it attained its highest development and flourished most. For here the Jews began to busy themselves with Greek literature even under their client rulers, the first Ptolemies, and here in the diaspora the other Scriptures were first translated into Greek; here the process of fusion began. But at last, and in the greatest rapidity; here, therefore, also the Jews first engaged in a scientific study of Greek philosophy and transplanted that philosophy to the soil of Judaism. We read of a Jewish philosopher Aristobulus in the time of Ptolemy VI. Philometer, in the middle of the 2nd century B.C., of whose philosophical commentary on the Pentateuch fragmenfs have been preserved by Clement of Alexandria and Eusebius. So far as we can judge from these, his aim was to put upon the sacred text a sense which should appeal even to Greek readers, and in particular to get rid of all anthropomorphic utterances about God. Philo therefore regards him as a Peripatetic. We may be sure that this philosophical line of thought had its representatives in Alexandria between the times of Aristobulus and Philo, but we are not acquainted with the names of any such. Philo certainly, to judge by his historical influence, was the greatest of all these Jewish philosophers, and in his case we can follow in detail the methods by which Greek culture was harmonized with Jewish faith. On one side he is quite a Greek, on the other quite a Jew. His language is formed on the best classical models, especially Plato. He knows and often cites the great Greek poets, particularly Homer and the tragedians, and his chief study was in Greek philosophy, and he speaks of Heraclitus, Plato, the Stoics and the Pythagoreans from among the highest veneration. He had appropriated their doctrines so completely that he must himself be reckoned among the Greek philosophers; his system was eclectic, but the borrowed elements are combined into a new unity with so much originality that at the same time he may fairly be regarded as representing a philosophy of his own, which has for its characteristic feature the constant prominence of a fundamental religious idea. Philo's closest affinities are with Plato, the later Pythagoreans and the Stoics. 3 Yet with all this Philo remained a Jew, and a great part of his writings is expressly directed to recommend Judaism to the respect and, if possible, the acceptance of the Greeks. He was not a stranger to the specifically Jewish culture that prevailed in Palestine; in Hebrew he was not proficient, but the numerous etymologies he gives show that he had made some study of that language. 4 His method of exegesis is in point of form identical with that of the Palestinian scribes, and in point of matter coincidences are not absolutely rare. 5 But above all his whole works prove on every page that he felt himself to be thoroughly a Jew, and desired to be nothing else. Jewish "philosophy" is to him the true and highest wisdom; the knowledge of God and of things divine and human which is contained in the Mosaic Scriptures is to him the deepest and the purest.

If now we ask wherein Philo's Judaism consisted we must answer that it lies mainly in the formal claim that the Jewish people, in virtue of the divine revelation given to Moses, possesses the true knowledge in things religious. Thoroughly Jewish is his recognition that the Mosaic Scriptures of the Pentateuch are of absolute divine authority, and that everything they contain is valuable and significant because divinely revealed. The other Jewish Scriptures are also recognized as prophetic, i.e. as the writings of inspired men, but he does not place them on the same lines with the law, and he quotes them so seldom that we cannot determine the compass of his canon. The

2 See the list of these in Vallarsi's edition of Jerome (iii, 731-734), and compare Siegfried, "Philologische Studien," in Merz's Archiv. ii. 143-163 (1872).

3 See Siegfried, Philo, pp. 142-159.

4 The fathers of the Church have specially noticed his Platonic and Pythagoreanism; an old proverb even says, with some reserve, "Philo, Philo, like Plato and the Pythagoreans." (See Dr. Merx's edition of Philo and Suidas, ut supra.) Clement of Alexandria directly calls him a Pythagorean. Eusebius (H. E. ii. 4, 3) observes both tendencies. Recent writers, especially Zeller, lay weight also on his Stoic affinities, and with justice, for the elements which he borrows from Stoicism are as numerous and important as those derived from the other two schools.

5 See the list of these in Vallarsi's edition of Jerome (iii, 731-734), and compare Siegfried, "Philologische Studien," in Merz's Archiv. ii. 143-163 (1872).

---
decisive and normative authority is to him the "holy laws" of Moses, and this not only in the sense that everything they contain is true but that all truth is contained in them. Everything that is right and good in the doctrines of the Greek philosophers had already been quite as well, or even better, taught by Moses. Thus, since Philo had been deeply influenced by the teachings of Greek philosophy he actually finds in the Pentateuch everything which he had learned from the Greeks. From these premises he assumes as requiring no proof that the Greek philosophers must in some way have drawn from Moses, a view indeed which is already expressed by Aristobulus. To carry out these presuppositions called for an exegetical method which seems very strange to us, that, namely, of the allegorical interpretation of Scripture. The allegorical method had been practiced before Philo's date in the rabbinical schools of Palestine, and he himself expressly refers to its use by his predecessors, nor does he feel that any further justification is requisite. With its aid he discovers indications of the profoundest doctrines of philosophy in the simplest stories of the Pentateuch.  

1. The merely formal principle of the absolute authority of Moses is really the one point in which Philo still holds to genuinely Jewish conceptions. In the whole substance of his philosophy the Jewish point of view is more or less completely modified—sometimes almost extinguished—by what he has learned from the Greeks. Comparatively speaking, he is most truly a Jew in his conception of God. The doctrine of monothelism, the stress laid on the absolute majesty and sovereignty of God above the world, the principle that He is to be worshipped without images, are all points in which Philo justly feels his superiority to a Jew over popular heathenism. But only over popular heathenism, for the Greek philosophers had long since arrived at least at a theoretical monothelism, and their influence on Philo is nowhere more strongly seen than in the detailed development of his doctrine of God. The specifically Jewish (i.e. particularistic) conception of the election of Israel, the obligation of the Mosaic law, the future glory of the chosen nation, have almost disappeared; he is really a cosmopolitan and praises the Mosaic law just because he deems it cosmopolitan. The true sage who follows the law of Moses is the citizen not of a particular state but of the world. A certain attachment which Philo still manifests to the particularistic conceptions of his race is meant only "in majore Judaeorum gloriam." The Jewish people has remained the most faithful of God; in their midst it has the most virtuous ancestry and is itself distinguished for virtue. The Mosaic law is binding, but only because it is the most righteous, humane and rational of laws, and even its outward ceremonies always disclose rational ideas and aims. And lastly, outward prosperity is promised to the pious, even on earth, but the promise belongs to all who turn from idols to the true God. Thus, in the whole substance of his view of the universe, Philo occupies the standpoint of Greek philosophy rather than of national Judaism, and his philosophy of the world and of life can be completely set forth without any reference to conceptions specifically Jewish.

His doctrine of God starts from the idea that God is a Being absolutely bare of quality. All quality in finite beings has limitation, and no limitation can be predicated of God, who is eternal, unchangeable, simple substance, free, self-sufficient, better than the good and the beautiful. To predicate any quality (toubròs) of God would be reducing Him to the sphere of finite existence. Of Him we can say only that He is, not what He is, and such purely negative predications as to His being appear to Philo, as to the later Pythagoreans and the Neoplatonists, the only way of securing His absolute elevation above the world. At bottom, no doubt, the meaning of these negative predications is not "nothing," the highest and most perfect being; and so, conversely, we are told that God contains all perfection, that He fills and encompasses all things with His being.

A consistent application of Philo's abstract conception of God would exclude the possibility of any active relation of God to the world, and therefore of religion, for a Being absolutely without quality and movement cannot be conceived as actively concerned with the multiplicity of individual things. And so in fact Philo does teach that the absolute perfection, purity and loftiness of God would be violated by direct contact with imperfect, impure and finite things. But the possibility of a connexion between, and the world is reached through a distinction which forms the most important point in his theology and cosmology; the proper Being of God is distinguished from the infinite multiplicity of divine Ideas or Forces: God himself is without quality, but He disposes of an infinite variety of divine Forces, through whose mediation an active relation of God to the world is brought about. In the details of his teaching as to these mediating entities Philo is guided partly by Plato and partly by the Stoics, but at the same time he makes use of the concrete religious conceptions of heathenism and Judaism. Following Plato, he first calls them Ideas or ideal patterns of all things; they are thoughts of God, yet possess a real existence, and were produced before the creation of the sensible world, of which they are the types. But, in distinction from Plato, Philo's ideas are at the same time efficient causes or Forces (δύναμες), which bring unformed matter into order conformatly to the patterns within themselves, and are in fact the media of all God's activity in the world. This modification of the Platonic Ideas is due to Stoic influence, which appears also when Philo gives to the Ideas or δύναμες the name of λόγος, i.e. operative ideas—parts, as it were, of the operative Reason. For, when Philo calls his mediating entities λόγος, the sense designed is analogous to that of the Stoics when they call God the Logos, i.e. the Reason which operates in the world. But at the same time Philo maintains that the divine Forces are identical with the "daemons" of the Greeks, and the "angels" of the Jews, i.e. servants and messengers of God by means of which He communicates with the finite world. All this shows how uncertain was Philo's conception of the nature of these mediating Forces. On the one hand they are nothing else than Ideas of individual things conceived in the mind of God, and as such ought to have no other reality than that of immanent existence in God, and so Philo says expressly that the totality of Ideas, the λόγων οἰκονομία is simply the Reason of God as Creator (θεός λόγος ἡς κοσμοποιεῖτο). Yet, on the other hand, they are represented as hypostases distinct from God, individual entities not dependent upon Him but independent, a doctrine, however, as Zeller and other recent writers have justly remarked, is necessarily involved in Philo's premises, for, on the one hand, it is God who works in the world through His Ideas, and therefore they must be identical with God; but, on the other hand, God is not to come into direct contact with the world, and therefore the Forces through which He works must be distinct from Him. The same inevitable amphiboly dominates in what is taught as to the supreme Idea or Logos. Philo regards all individual Ideas as comprehended in one highest and most general Idea or Force—the unity of the individual Ideas—which he calls the Logos or Reason of God, and which is once again regarded as operative Reason, that is, the Reason which operates in the world, the firstborn son of God, the archangel who is the vehicle of all revelation, and the high priest who stands before God on behalf of the world. Through him the world was created, and so he is identified with the creative Word of God in Genesis (the Greek λόγος meaning both "reason" and "word"). Here again, we see, the philosopher is unable to escape from the difficulty that the Logos is at once the immanent Reason of God, and yet also an hypostasis standing between God and the world. The whole doctrine of this mediatorial hypostasis is a strange intertwining of very dissimilar threads; on one side the way was prepared for it by the older Jewish concept of the Angel of the Lord, in which we find the beginnings even in the Old Testament (Job xxxviii. 12 seq.; Prov. viii., ix.), and the fuller development in the books of Ecclesiastics and Wisdom, the latter of which comes very near to Philo's ideas if we substitute for the term "wisdom"

1 For details, see Gröber, Philo, i. 68 seq.; Zeller, Phil. der Gr. (3rd ed., vol. iii., pt. ii., pp. 346-352); Siegfried, Philo, pp. 160 seq.
II. Philo's most important work is the Νόμος Ιερος Ἀληθείας (Euseb. H. E. ii. 18, 1; Phot. Biblioth. Cod. 103), a vast and copious allegorical commentary on Genesis, dealing with chaps. i.-iv., verse by verse, and with selected passages from other books. The readers in view are mainly Jews, for the form is modelled on the rabbinic Midrash. The main idea is that the characters which are Genesis are allegories of states of the soul (φυσις ἐν ψυχῃ). All persons and actions being interpretable in this sense, the work as a whole is a very extensive body of psychology and ethics. It begins with Gen. ii. 1, for the De mundi opificio, and which is the summary of the understanding of the world through to this series of allegorical commentaries, but deals with the actual history of creation, and that under quite a different literary form. With this exception, however, the Νόμος Ιερος Ἀληθείας includes all the treatises in the first volume of M. Auctt. Aucher.

Φιλό's literary labours have a twofold object, being directed either to expound the true sense of the Mosaic law, i.e., the philosophy which we have just described, to his Jewish brethren, or to convince heathen readers of the excellence, the supreme purity and truth, of the Jewish religion, whose holy records contain the deepest and most perfect philosophy, the best and most humane legislation. Thus as a literary figure Philo, in conformity with his education and views, appears in the eyes of the modern world, to regain the Jews for Hellenism and the Greeks for Judaism, yet always taking it for granted that his standpoint really is Jewish, and just on that account truly philosophical and cosmopolitan.

The titles of the numerous works of Philo present at first sight a most confusing multiplicity. More than three-fourths of them, however, are really mere sections of a small number of larger works. Three such great works on the Pentateuch can be distinguished.

1. The smallest of these is the Εὐαγγέλια καὶ λόγους (Quaestiones et solutiones), a short exposition of Genesis and Exodus, in the form of question and answer. The work is cited under the title books 16-19, 25, 26; Peh. vii. 1-14. Philo himself, and later writers, but the Greek text is now almost lost, and only about one-half preserved in an Armenian translation. Genesis seems to have occupied six books. Eusebius tells us that Exodus filled five books. In the Armenian translation, the first books are in the first edited Mochtar, J. Bapt. Aucher, in 1826, are preserved four books on Genesis and two on Exodus, but with lacunae. A Latin version of it later has been printed under the title "De exodo et quasqu. ... super Genes.," was first printed at Paris in 1520. Of the Greek we have numerous but short fragments in various Florilegia. The interpretations in this work are partly literal and partly allegorical.

2. See Opp. ed. Mangy, ii. 648-650; Mai, op. cit., vol. vii. pt. i. 439 sqq.; ed. Planck, in "De exodo et quasqu. ... super Genes.," was first printed at Paris in 1520. Of the Greek we have numerous but short fragments in various Florilegia. The interpretations in this work are partly literal and partly allegorical.

3. A work of a very different kind is the group of writings which we may call "An Exposition of the Mosaic law for Gentiles," which, in spite of their very various contents, present on nearer inspection a remarkable harmony. In the latter works Philo seeks to give an orderly view of the chief points of the Mosaic legislation in the Pentateuch, and to recommend it as valuable to Gentile readers. The method of exposition is somewhat more elaborate than in the previous books. The arrangement of the chief method of interpretation is not wholly excluded, the main object is to give such a view of the legislation as Philo accepted as historical. This work has three main divisions: (a) an Account of the Generations (οἰκογενεία), in which Moses puts first to show that his
legislation was conformed to the will of nature, and that therefore those who followed it were true cosmopolitans; (b) the Biographies of the Virtuous—so to speak—are the representatives of Virtue, in the manner of the Heroes—who are described in the mythology of the ancients with the rubrics of the decalogue, arranged under the headings of certain cardinal virtues.

The treatises which belong to this work are the following: (1) Περὶ τῶν στατικῶν νόμων, εἰς Ἀλεξάνδρα (De Abrahomo, M. ii. 1-42). This work does not fall within the number of the allegorical commentaries. On the other hand, the introduction to the treatise De Abrahamo makes clear its immediate connection with the De mandi sacrificiis. The first book of the treatise De Abrahamo contains the allegorical commentaries, which are at present usual in the editions, seems indeed to go back to a very early date, for even Eusebius cites a passage from it in the second treatise of his Evangelies (H.E. ii. 237-250); (2) Περὶ τῶν νομίμων ἡμῶν καὶ τῶν ἱπταμένων (De legatione, M. ii. 405-407). This work has a very intimate connection with the treatise De Abrahamo. First, Philo relates how the Roman Governor Flaccus in Alexandria, towards the beginning of the reign of Caligula, allowed the Alexandrians, without interfering at all, to erect a statue of Zeus, that this may be seen in the grossest manner, and even to persecute them to the shedding of blood. In the second he tells how the Jews had been subjected to still greater sufferings through the command of Caligula that fifteen years should pass before Jews would be allowed to eat the flesh of the king of Egypt. This is what the Jews of Alexandria in vain sought relief by a mission to Rome which was headed by Philo. But both together were only parts of a larger work, in five books, of which the first two and the last have been edited, with a Latin translation, by A. Giussani (see below), 1822. It is mentioned by its Greek title in Eusebius (H.E. ii, 18, 6; Præp. Ev. vii. 20 fn., viii. 13 fn., ed. Gaisford). The Armenian text gives two books, but of these the first, if genuine at all, in any rate appears only in an abridged and somewhat revised state. Eusebius (Præp. Ev. viii. 14) quotes from the second book in that extent to amount that it series of excerpts from the whole. The short passage in Præp. Ev. viii. 14, however, seems to be connected with the pœuli, or change of Jewish fortunes for the better. Thus we make out five books in all—the number actually given by Eusebius (H.E. ii. 5, 1). (3) Περὶ πιερί (De providentia). This work was not reached until recent times. A portion of the earlier, and a portion of the later, has been edited, with a Latin translation, by A. Giussani (see below), 1822. It is mentioned by its Greek title in Eusebius (H.E. ii, 18, 6; Præp. Ev. vii. 6, 7). The title, however, has a show, means "Counsels," "Recommendations," the reference being to such laws of the Decalogue as might be of use to Jewish readers. (4) Περὶ κοινωνίας (De M.); in which the text appears as being certain to the present day. This contains a single work of the Therapeutae (q.). Having their home on the shores of Lake Mareotis. These were held by Eusebius and many other Christian writers to be the earliest of the Jewish works, which of course could not be the case, as it was a genuine work of Philo. This account, amongst others, it was held to be spurious by Graetz and P. E. Lucas; and this view gradually received the assent of most modern scholars. Latterly, however, J. J. Haseleu has shown with great thoroughness that in language and thought alike it is essentially Philonic, and the genuineness of the book has also been affirmed by P. Wendland, Z. Frankel, and J. Bernays, has been successfully defended by F. Cumont. (5) Περὶ τῶν συναξάρτων (De mundo). It is generally agreed that, in L. van der Loh's words, this is "nothing but a compilation of various portions of the Περὶ ἀκακεμενῶν κοίμων and other Philonic works." (6) Two discourses, De Samponio de Leno, extant only in Armenian, and certain other writings of the same kind. These appear only in the Armenian, and they are brought by the current sort of criticism to claim to his work. (7) Περὶ τῶν παρασκευῶν εἰς Θεόν (Quod omnis probus liber sit) has been questioned by Z. Frankel and R. Ansfeld; but their arguments would rather point to its being a work of Philo of Alexandria. We believe that the same case. (8) Περὶ προνοιας (De providentia), which we possess as a whole

3 This conjecture is Dähne's, Theol. Stud. u. Krit. (1831), pp. 399, 1037.
PHILO OF BYZANTIUM—PHILODEMUS

only in an Armenian version, consists of two books, the first of which appears to be in a Christian recension, but there is no reason for denying its Philonic origin.

Editions.—Till recent days the best edition was that of Mangy (2 vols., London, 1857); the handling of the Hultze doddleco (Leipzig, 1851). Both are still very useful, but for scholars they will be superseded by the enlarged and critical edition of Loepold Cohn and Paul Wendland (Berlin, 1896—1902). See also papers by Cohn in Hermes, xxxviii. (1903) and xiii. (1908). There is an English translation of the old text by C. D. Yonge (4 vols., London, 1854).

PHILO OF BYZANTIUM, Greek philosopher on mechanics, flourished during the latter half of the 2nd century B.C. (according to some, a century earlier). He was the author of a large work Μηχανική σβατρα (56 pieces), of which the fourth and (in epitome) first books treat of the construction of fortresses, provisioning, attack and defence (ed. R. Schmidt, 1803, with German translation in H. Köchly's Griechische Kriegs-schriftsteller, vol. i. 1853; E. A. Rochas d'Aiglun, Piochoristeque des Grèc., 1872). Another portion of the work, on pneumatic engines, has been preserved in the form of a Latin translation (De ingenii spiritualibus) made from an Arabic version (ed. W. Schmidt, with German translation, in the works of Heron of Alexandria, vol. i, in, "Teubner Series," 1893; with French translation by Rochas, La Science des philosophes . . . dans l'antiquité, 1882).

A fragment on The Seven Wonders of the World, wrongly attributed to Philo, probably belongs to the 6th century A.D. It is printed in R. Hercher's Ilian (1858).

PHILO OF LARISA, Greek philosopher of the first half of the 1st century B.C. During the Mithradact wars he left Athens and took up his residence in Rome. He was a pupil of Clitomachus, whom he succeeded as head of the Third or New Academy (see Academy, Greek). In Rome he lectured on rhetoric and philosophy, and collected around him many eminent students, amongst whom Cicero was the most famous and the most enthusiastic. None of his works is extant; our knowledge of his views is derived from Numenius, Sextus Empiricus, and Cicero. In general, his philosophy was a reaction against the sceptic or agnostic position of the Middle and New Academy in favour of the dogmatism of Plato.

See Gray, Die Akademiker Philo und Antiochus (1849); Hermann, De Philone Larissaeo (Göttingen, 1851 and 1852)

PHILO, HEREMNIUS, of Byblus, Greek grammarian, was born, according to Suidas, in A.D. 42. He lived into the reign of Hadrian, of which he wrote a history, now lost. He was the author of various works: On the Acquisition and Choice of Books; On Cities and their Famous Men, epitomized by the grammarians Aelianus Serosenus, and one of the chief authorities used by Hesychius and Stephanus of Byzantium; On Synonyms, of which there is an extant epitome by Ammonius Grammaticus. But he is chiefly known for his translation of the Philonic history of Sanchuniathon, who was said to have lived before the Trojan War. Of this work considerable fragments have been preserved, chiefly by Eusebius in the Praeparatio evangelica (i. 9, 10; iv. 16). They present a chameleonisch rechtzuffe of Philonic theology and mythology, which is represented as translated from the original Phoenician. Sanchuniathon is probably an imaginative personage, whose name is formed from that of the Philonic god Sanchon.

Editions of the fragments by J. C. Orelli (1826) and C. Müller, Frag. hist. graec. vol. iii. In 1836 F. Wagenfeld brought out what claimed to be a complete translation by Philo (from a MS. discovered in a convent in Portugal, now considered spurious). There are also two modern translations by J. P. Cory (1828) and Bishop R. Cumberland (1770).

PHILOCHRUS, of Athens, Greek historian during the 3rd century B.C., was a member of a priestly family. He was a seer and interpreter of signs, and a man of considerable influence. He was strongly anti-Macedonian in politics, and a bitter opponent of Demetrius Poliorcetes. When Antigonus Gonatas, the son of the latter, besieged and captured Athens (261), Philochrus was put to death for having supported Ptolemy Philadelphus, who had encouraged the Athenians in their resistance to Macedonia. His investigations into the usages and customs of his native Attica were embodied in an Attikis, a seventeen books, a history of Athens from the earliest times to 262 B.C. Considerable fragments are preserved in the lexicographers, scholiasts, Athenaeus, and elsewhere. The work was epitomized by the author himself, and later by Asinius Pollio of Tralles (perhaps a freedman of the famous Galus Asinius Pollio). Philochrus also wrote on oracles, divination and sacrifices; the mythology and religious observances of the tetrapolis of Attica; the myths of Sophocles; the lives of Euripides and Pythagoras; the foundation of Salamis. He compiled chronological lists of the archons and Olympiads, and made a collection of Attic inscriptions, the first of its kind in Greece.

PHILOCTETES, in Greek legend, son of Poeeas king of the Malians of Mt. Oeta, one of the suitors of Helen and a celebrated hero of the Trojan War. Homer merely states that he was distinguished for his prowess with the bow; that he was bitten by a snake on the journey to Troy and left behind in the island of Lemnos; and that he subsequently returned home in safety. These brief allusions were elaborated by the "cyclic" poets, and the adventures of Philoctetes formed the subject of tragedies by Aeschylus, Sophocles and Euripides. In the later form of the story Philoctetes was the friend and armour-bearer of Heracles, who presented him with his bow and poisoned arrows as a reward for kindling the fire on Mt. Oeta, on which the hero and Philoctetes had spent the last nine years of the tenth year of the war. An oracle having declared that Troy could not be taken without the arrows of Heracles, Odysseus and Diomedes (or Neoptolemus) were sent to fetch Philoctetes. On his arrival before Troy he was healed of his wound by Machaon, and slew Paris; shortly afterwards the city was taken. On his return to his own country, finding that a revolt had broken out against him, he again took ship and sailed for Italy, where he founded Petilia and Cremissa. He fell fighting on the side of a band of Rhodian colonists against some later immigrants from Pallene in Achaea. His tomb and sanctuary were shown at Macalla, on the coast of Bruttium.

Of the Aeschylean and Euripidean tragedies only a few fragments remain. One of the best is the part of the other, dealing with the fortunes of Philoctetes before Troy, is lost. Some light is thrown upon the lost plays by Dio Chrysostom, who in one of his discourses (92) describes his reading of parts; like him, he is brought back in time of need. His connexion with the fall of Troy indicates that the fire-god himself set fire to the city; in like manner no other than the fire-god was thought worthy to kindle the pyre of Heracles. See Homer, Iliad, vii. 564; 302 (Derby); Philo- ketes, and Jebb's Introduction; Diod. Sic. iv. 38; Philostratus, Heroica, 6; Strabo vi. 254; Hyginus, Fab. 36, 102.

PHILODEMUS, Epicurean philosopher and poet, was born at Gadara in Coele-Syria early in the 1st century B.C., and
settled in Rome in the time of Cicero. He was a friend of Calpurnius Fiso, and was implicated in his profiliogpy by Cicero (in *Pisonem*, 29), who, however, praises him warmly for his philosophic views and for the *delegans lassicia* of his poems (cf. Horace, *Satires*, i. 2. 120). The Greek anthology contains thirty-four of his epigrams. From the excavations of the villa at Herculanenum (q.v.) there have been recovered thirty-six treatises attributed to Philodemus, and it has been suggested that the villa was actually owned by him; but this is generally denied. These works deal with music, rhetoric, ethics, signs, virtues and vices, and defend the Epicurean standpoint against the Stoics and the Peripatetics.

The *Rhetorica* has been edited by Sudhaus (1892–1905); the De *Ira* and the De *Pietate* by Oppert (1864 to 1865); the De *Musica* by Kempl (1884); De *Vitis* by Ussing (1868); De *Morte* by Meikle (1872). Philolaus was the first to propose the doctrine of the Pythagorean number theory, particularly dwelling on the properties inherent in the decad—the sum of the first four numbers, consequently the fourth triangular number, the *tetractys* (see *Vit. Pythag. ap. Phot. Bibli. p. 712*)—which he called great, all-powerful, and all-producing. The great Pythagorean oath was taken by the sacred *tetractys*. The discovery of the regular solids is attributed to Pythagoras by Eudemus, and Empedocles is stated to have been the first who maintained that there were four elements. Philolaus, connecting these ideas, held that the earth was spherical in form, and assigned the tetrahedron to fire, the octahedron to air, the icosahedron to water, and the cube to earth; the dodecahedron he assigned to a fifth element, aether, or, as some think, to the universe (see Plut. de Pl. Ph. ii. 6, ἐκ δέ τοῦ δωδεκάεδρου τὴν τοῦ παντὸς σφαίραν καὶ Στοβ. *Ed. Phys.* i. 10, ὅ τις σφάιρας ἄκλιτον). This theory, however superficial from the standpoint of observation, indicates considerable knowledge of geometry and gave a great impulse to the study of the science. Following Parmenidés, Philolaus regarded the soul as a "mixture and harmony" of the bodily parts; he also assumed a substantial soul, whose existence in the body is an exile on account of sin.

Philolaus said that the sphere of the fixed stars, the five planets, the sun, moon and earth, all moved round the central fire, which he called the hearth of the universe, the house of Zeus, and the mother of the gods (see Stob. *Ed. Phys.* i. 488); but as these made up only nine revolving bodies he conceived, in accordance with his number theory, a tenth, which he called counter-earth, *ἀρρίθμησιν*. He supposed the sun to be a disk of glass which reflects the light of the universe. He made the lunar month consist of 29½ days, the lunar year of 354, and the solar year of 365. Days. He was the first who published a book on the Pythagorean doctrines, a treatise of which Plato made use in the composition of his *Timaeus*. This work of the Pythagorean, to which the mystical name *Báxhα* is sometimes given, seems to have consisted of three books: (1) *Περὶ κόσμου*, containing a general account of the origin and arrangement of the universe; (2) *Περὶ φῶςυς*, an exposition of the nature of numbers; (3) *Περὶ ὑποχρήσεω*, on the nature of the soul.

**PHILOLOGY**, the generally accepted comprehensive name for the study of the word (Gr. λόγος), or languages; it designates that branch of knowledge which deals with human speech, and with all that speech discloses as to the nature and history of man. Philology has two principal divisions, corresponding to the two uses of "word" or "speech," as signifying either what is said or the language in which it is said. Either the thought expressed—which, when recorded, takes the form of literature—or the instrumentality of its expression: these divisions are the literary and the linguistic. Not all study of literature, indeed, is philological: as when, for example, the records of the ancient Chinese are ransacked for notices of astronomical or meteorological phenomena, or the principles of geometry are learned from the textbook of a Greek sage; while, on the other hand, to study Ptolemy and Euclid for the history of the sciences represented by them is philological more than scientific. Again, the study of language itself has its literary side: as when the vocabulary of a community (say of the ancient Indo-Europeans or Aryans) is taken as a document from which to infer the range and grade of knowledge of its speakers, their circumstances and their institutions. The two divisions thus do not admit of absolute distinction and separation, though for some time past tending toward greater independence. The literary is the older of the two; it even occupied until recently the whole field, since the scientific study of language itself has arisen only within the 19th century. Till then, literary philology included linguistic, as a merely subordinate and auxiliary part, the knowledge of a language being the necessary key to a knowledge of the literature written in that language. When, therefore, instead of studying each language separately as the science of its own literature men began to compare one language with another, in order to bring to light their relationships, their structures, their histories, the name "comparative philology" naturally enough suggested itself and came into use for the new method; and this name, awkward and trivial though it may be, has become so firmly fixed in English usage that it can be only slowly, if at all, displaced. European usage (especially German) tends more strongly than English to restrict the name philology to its older office, and to employ for the recent branch of knowledge a specific term, like those that have gained more or less currency with us also; as glottic, glossiography, linguistics, scientific, science of language, and the like. It is not a question of absolute propriety or correctness, since the word philology is in its nature wide enough to imply all language-study of whatever kind; it is one, rather, of the convenient distinction of methods that have grown too independent and important to be any longer well included under a common name.

I.—*The Science of Language in general.*

Philology, in all its departments, began and grew up as classical; the history of our civilization made the study of Greek and Latin long the exclusive, still longer the predominant and regulating, occupation of secular scholarship. The Hebrew and its literature were held apart, as something of a different order, as sacred. It was not imagined that any tongue to which culture and literature did not lend importance was worthy of serious attention from scholars. The first essays in comparison, likewise, were made upon the classical tongues, and were as erroneous in method and fertile in false conclusions as was to be expected, considering the narrowness of view and the controlling prejudices of those who made them; and the "Science of Hebrew" to the comparison only added to the confusion. The change which the past century has seen has been a part of the general scientific movement of the age, which has brought about the establishment
of so many new branches of knowledge, both historical and physical, by the abandonment of shackling prejudices, the freedom of inquiry, the recognition of the dignity of all knowledge and the wide-reaching assimilation of knowledge, and the resulting constant improvement of method. Literary philology has had its full share of advantage from this movement; but linguistic philology has been actually created by it out of the crude observations and wild deductions of earlier times, as truly as chemistry out of alchemy, or geology out of diluvianism. It is unnecessary here to follow out the details of the development; but we may well refer to the decisive influence of one discovery, the decisive action of one scholar. It was the discovery of the special relationship of the Aryan or Indo-European languages, depending in great measure upon the introduction of the Sanskrit as a term in their comparison, and demonstrated and worked out by the German scholar Bopp, that founded the science of linguistic philology. While there is abundant room for further improvement, it yet appears that the grand features of philologic study, in all its departments, are now so distinctly drawn that no revolution of its methods, but only their modification in minor respects, is henceforth probable. How and for what purposes to investigate the literature of any people (philology in the more proper sense), combining the knowledge thus obtained with that derived from other sources; how to study and set forth the material and structure and combinations of a language (grammar), or of a body of related languages (comparative grammar); how to co-ordinate and interpret the general phenomena of languages, as variously illustrated in the infinitely varying facts of different tongues, so as to exhibit its nature as a factor in human history and its methods of life and growth (linguistic science)—these are what philology teaches.

The study of language is a division of the general science of anthropology (q.v.), and is akin to all the rest in respect to its analogy to objects and its methods. Man as we now see him is twofold being: in part the child of nature, as to his capacities and desires, his endowments of mind and body; in part the creature of education, by training in the knowledge, the arts, the social conduct, of which his predecessors have gained possession. And the problem of anthropology is this: how natural man has become cultivated man; how a being thus endowed by nature should have begun and carried on the processes of acquisition which have brought him to his present state. The results of his predecessors' labours are not transmitted for his benefit into natural instincts, in language or in anything else. The child of the most civilized race, if isolated and left wholly to his own resources, aided by neither the example nor the instruction of his fellows, would no more speak the speech of his ancestors than he would build their houses, fashion their clothes, practise any of their arts, inherit their knowledge or wealth. In fact, he would possess no language, no arts, no wealth, but would have to go to work to acquire them, by the same processes which began to win them for the first human beings. One advantage he would doubtless enjoy: the descendant of a cultivated race has an enhanced aptitude for the reception of cultivation; he is more cultivable; and this is an element that has to be allowed for in comparing present conditions with past, as influencing the rate of progress, but nothing more. In all other respects it is man with the endowments which we now find him possessed of, but destitute of the gradually accumulated results of the exercise of his faculties, whose progress we have to explain. And it is, as a matter of necessity, by studying recorded historical and literary records of acquisition, and transferring these, with due allowance for different circumstances, to its more primitive periods, that the question of first acquisition or origin is to be solved, for language as for tools, for arts, for family and social organization, and the rest. There is just as much and just as little reason for assuming miraculous interference and aid in one of these departments as in another. If men have been left to themselves to make and improve instruments, to form and perfect modes of social organization, by implanted powers directed by natural desires, and under the pressure of circumstances, then also to make and change the signs that constitute their speech. All expressions, as all instruments, are apt to become or to be transmuted by the labours and inventions of those who use them; the same will have been the case in the unknown or prehistoric past. And we command now enough of the history of language, with the processes of its life and growth, to determine with confidence its mode of origin—within certain limits, as will appear below.

It is beyond all question, in the first place, that the desire of communication was the only force directly impelling men to the production of language. Man's sociality, his disposition to band together with his fellows, for lower and for higher purposes, for mutual help, and for sympathy, is one of his most fundamental characteristics. To understand those about one and to be understood by them is now, and must have been from the very beginning, a prime necessity of human existence; we cannot conceive of man, even in his most undeveloped state, as without the recognition of it. Communication is still the universally recognized office of speech, and to the immense majority of speakers the only one; the common man knows no other, and can only with difficulty and imperfectly be brought to see that there is any other; of the added distinctness and reach of mental action which the possession of such an instrumentality gives him he is wholly unconscious: and it is obvious that what the comparatively cultivated being of to-day can hardly be made to realize he has not yet acted upon the first men as a motive to action. It may perhaps be made a question which of the two uses of speech, communication or the facilitation of thought is the higher; there can be no question, at any rate, that the former is the broader and the more fundamental. That the kind and degree of thinking which we do nowadays would be impossible without language-signs is true enough; but so also it would be impossible without written signs. That there was a time when men had to do what mental work they could without the help of writing, as an art not yet devised, we have no difficulty in realizing, because the art is of comparatively recent device, and there are still communities enough that are working without it; it is much harder to realize that there was a time when speaking also was an art not yet attained, and that men had to carry on their rude and rudimentary thinking without it. Writing too was devised for conscious purposes of communication only; its esoteric uses, like those of speech, were at first unsuspected, and incapable of acting as an inducement; they were not noticed until made experience of, and then only by those who look beneath the surface of things. There is no analogy closer and more instructive than this between speech and writing. But analogies are abundant elsewhere in the history of human development. Everywhere it is the lower and more obvious inducements that are first effective, and that lead gradually to the possession of what serves and stimulates higher wants. All the arts and industries have grown out of men's effort to get enough to eat and protection against cold and heat—just as language, with all its uses, out of men's effort to communicate with their fellows. As a solitary man now would never form even the beginnings of speech, as one separated from society unlearns his speech by disuse and becomes virtually dumb, so early man, with all his powers, would never have acquired speech, save as to those powers was added sociality with the needs it brought. We might conceive of a solitary man as housing and dressing himself, devising rude tools, and thus lifting himself a step from wildness toward civilization; but of the process of getting something to talk—of the recognition of the impulse to communication as the efficient cause of language-making is an element of primary importance in the theory of the origin of language. No one who either leaves it out of account or denies it will, however ingenious and entertaining his speculations, cast any real light on the earliest history of speech. To inquire under what peculiar circumstances, in connexion with what mode of individual or combined action, a first outburst of oral expression may have taken place, is, on
The other hand, quite futile. The needed circumstances were always present when human beings were in one another's society; there was an incessant drawing-on to attempts at mutual understanding which met with occasional, and then ever more frequent and complete success. There inheres in most reasoning upon this subject the rooted assumption, governing opinion even when not openly upheld or consciously made, that conceptional and real natural names, and that in a state of nature these will somehow break forth and reveal themselves under favoring circumstances. The falsity of such a view is shown by our whole further discussion.

The character of the motive force to speech determined the character of the beginnings of speech. That was first signified by the act of gesture. It was a far more natural signification of ideas and purpose. As judged by any standard which we can apply to it, or first in order of conceptual development. All attempts to determine the first spoken signs by asking what should have most impressed the mind of primitive man are and must be failures. It was the exigencies and possibilities of practical life, in conditions quite out of reach of our distinct conception, that prescribed the earliest signs of communication. So, by a true and constructive analogy, the beginnings of writing are rude depictions of visible objects; it is now thoroughly recognized that no alphabet, of whatever present character, can have originated in any other way; everything else is gradually arrived at from that—; as, indeed, in the ingeniously shaping hands of man, from any central body of signs, though but of small extent, all else is attainable by processes of analogy and adaptation. Transfer. Now what is it that is directly signifiable in the world about us? Evidently the separate acts and qualities of sensible objects, and nothing else. In writing, or signification to the eye, the first element is the rude depiction of the outline of an object, or of that one of the sum of its characteristic qualities which the eye takes note of and the hand is capable of intelligibly reproducing; from that the mind understands the whole complex object itself, and then whatever further may in the circumstances of its use be suggested by it. So, for example, the picture of a tree signifies primarily a tree, then perhaps wood, something made of wood, and so on; that of a pair of outstretched wings signifies secondarily flight, then soaring, height, and whatever else these may lead to. No concept, however, is ever in itself the signification; it is a facile analysis of its constituent qualities and a selection of the one which is both sufficiently characteristic in itself and capable of being called up by a sign before the mind addressed.

And what quality shall be selected depends in great measure upon the instrumentality used for its signification. Of such instrumentality men possess a considerable variety. We must leave out of account that of depiction, as an instance, because its employment belongs to a much more advanced state of cultivation, and leads the way to the invention not of speech but of the analoguous and auxiliary art of writing. There remain gesture, or changes of position of the various parts of the body, especially of the most mobile parts, the arms and hands; grimace, or the changes of expression of the features of the countenance (in strictness, a variety of the preceding); and utterance, or the production of audible sound. It cannot be doubted that, in the first stages of communicative expression, all these three were used together, each for the particular purposes which it was best calculated to serve. The nearest approach to such action that is now possible is when two persons, wholly ignorant of one another's speech, meet and need to communicate—an imperfect correspondence, because each is trained to habits of expression and works consciously, and with the advantage of long experience, towards making himself understood, yet it is not purpose. What they do, to reach mutual comprehension, is like what the first speechless men, unconsciously and infinitely more slowly, learned to do: face, hands, body, voice, are all put to use. It is altogether probable that gesture at first performed the principal part, even to such extent that the earliest human language may be said to have been a language of gesture signs; indeed, there exist at the present day such gesture-languages as those in use between roving tribes of different speech that from time to time meet one another (the most noted example is that of the gesture-language, of a very considerable degree of development, of the tribe called the Korowai of New Guinea it is the natural resort of those who by deafness are cut off from ordinary spoken intercourse with their fellows. Yet there never can have been a stage or period in which all the three instrumentalities were not put to use together. In fact, they are still all used together; that is even now an ineffectual speech to which grime and gesture ("action," as Demosthenes called them) are not added as enforcers; and the lower the grade of development and culture of a language, the more important, even for intelligibility, is their addition. But voice has won to itself the voice of the chief and almost exclusive part in communication, insomuch that we call all communication, "language" (i.e. "tonguelness") just as a race of mutes might call it "handiness" and talk (by gesture) of a handiness of grimace. This is not in the least because of any closer connexion of the thinking apparatus with the muscles that act to produce audible sounds than with those that act to produce visible motions; not because there are natural uttered names for conceptions any more than natural gestures. Therefore, it is a survival of the fittest, or analogous to the process by which iron has become the exclusive material of swords, and gold and silver of money: because, namely, experience has shown this to be the material best adapted to this special use. The advantages of voice are innumerable and obvious. There is in the economy, as employing a mechanism that is available for little else, and leaving free for other purposes those indispensable instruments the hands. Then there is its superior perceptibility: its fine differences impress themselves upon the sense at a distance at which visible motions become indiscernible; they are not hidden by intervening objects; they allow the eyes of the listener as well as the hands of the speaker to be employed in other useful work; they are as plain in the dark as in the light; and they are able to catch and command the attention of one who is not to be reached in any other way. We might add as the third advantage a superior capability of variation and combination on the part of spoken sounds; but this is not to be insisted on, inasmuch as we hardly know to what extent or in what manner the want of flexibility in expression has been expended through all time upon its elaboration; and the superiority, however real, can hardly have been obvious enough to serve as a motive: certainly, there are spoken languages now existing whose abundance of resources falls short of what is attainable by gesture. Oral utterance is the form which expression has inevitably taken, the sum of man's endowments being what it is; but it would be a mistake to suppose that a necessity of any other kind is involved in their relation. The fundamental conditions of speech are man's grade of intellectual power and his social instinct; these being given, his expression follows, availing itself of whatever means it finds most suited to its purpose; if voice has been wanting it was taken to from gesture. So, in certain well-known cases, a marked artistic gift on the part of individuals deprived of the use of hands has found means of exercise in the feet instead. But men in general have hands, instruments of exquisite tact and power, to serve the needs of their intellect; and so voice also, to provide and use the tools of thought; there is no error in maintaining that the voice is given us for speech, if only we do not proceed to draw from such a dictum false conclusions as to the relation between thought and utterance. Man is created with bodily instruments suited to do the work prescribed by his mental capacities; therein lies the harmony of his environment, his equipment through instincts that all signification becomes directly suggestive. The first written signs are (as already noticed) the depictions of visible objects, and could be nothing else; and, by the same necessity, the first uttered signs were the imitations of audible sounds. To reproduce
any sound of which the originating cause or the circumstances of production are known, brings up of course before the conception that sound, along with the originator, or circumstances of origination, or whatever else may be naturally associated with it. There are two special directions in which this mode of sign-making is fruitful: imitation of the sounds of external nature (as the cries of animals and the noises of inanimate objects when in motion or acted on by other objects) and imitation of human sounds. The two are essentially one, in principle, although by some held apart, or even opposed to each other, as respectively the imitative or onomatopoetic and the expository or interjectional beginnings of speech; they differ only in their spheres of significance, the one being especially suggestive of external objects, the other of inward feelings. There are natural human tones, indicative of feeling, as there are natural gestures, poses, modes of facial expression, which either are immediately intelligible to us (as is the warning cry of the hen to the day-old chicken), or have their value taught us by our earliest experiences. If we hear a cry of joy or a shriek of pain, a laugh or a groan, we need no explanation in words to tell us what it signifies any more than when we see a sad face or a drooping attitude. So also the characteristic cry or act of anything outside ourselves, if even rudely imitated, is to us an effective reminder and awakener of conception. We have no reason to question that such were the suggestions of the beginnings of uttered expression. The same means have made their contribu-
tions to language even down to our own day; we call words so produced "onomatopoetic" (i.e. "name-making"), after the example of the Greeks, who could not conceive that actually new additions to language should be made in any other way. What and how wide the range of the imitative principle, and what amount of language-signs it was capable of yielding, is a subject of separate investigation—rather, of speculation, since anything like exact knowledge in regard to it will never be attained; and the matter is one of altogether secondary consequence; it is sufficient for our purpose that enough could certainly be won in this way to serve as the effective gerns of speech.

All the natural means of expression are still at our command, and are put to more or less use by us, and their products are as intelligible to us as they have been to any generation of our ancestors, back to the very first. They are analogous also to the means of communication of the lower animals, this so far as we know, consists in observing and interpreting one another's movements and natural sounds (where there are such). But language is a step beyond this, and different from it. To make language, the intent to signify must be present. A cry wrung out by pain, or a laugh of amusement, though intelligible, is not language; either of them, if consciously reproduced in order to signify to another pain or pleasure, is language. So a cough within hearing of any one attracts his attention; but to cough, or to produce any other sound, articulate or inarticulate, for the purpose of attracting another's attention, is to commit an act of language-making, such as in human history preceded in abundance the establishment of definite traditional signs they may be made. But the making of such signs must take place in the course of a process which begins with the varying uses of sounds. Here begins the complete cry shall advertise their fellows of the threat of danger, is as near an approach to it as is anywhere made.

But the actual permanent beginnings of speech are only reached when the natural basis is still further abandoned, and signs begin to be used, not because their natural suggestive-
ness is seen in them, but by imitation, from the example of others who have been observed to use the same sign for the same purpose. Then for the first time the means of communication becomes something to be handed down, rather than made anew by each indi-
vidual; it takes on that traditional character which is the essential character of all human institutions, which appears not less in the forms of social organization, the details of religious ceremonial, the methods of art and the arts, than in language. That all existing speech, and all known recorded speech, is purely traditional, cannot at all be questioned. It is proved even by the single fact that for any given conception there are as many different spoken signs as there are languages—say a thousand (this number is rather far within than beyond the truth), each of them intelligible to him who has learned to use it and to associate it with the conception to which it belongs, but unintelligible to the users of the nine hundred and ninety-nine other signs, as these are all unintelligible to him; unless, indeed, he learn a few of them also (by a vein at the beginning) and learned the one that he calls his own. What single sign, and what set of signs any individual shall use, depends upon the community into the midst of which he is cast, by birth or other circumstances, during his first years. That it does not depend upon his race is demonstrated by facts the most numerous and various; the African whose purity of descent is attested by every feature is found all over the world speaking just that language, or jargon, into the midst of which the fates of present or former slavery have brought his parents; every civilized community contains elements of various lineage, combined into one by unity of speech, and instances are frequent enough where whole nations speak a tongue of which their ancestors knew nothing; for example, the Celtic Gauls and the Germanic Normans of France speak the dialect of a geographically insignificant district in central Italy, while we ourselves can hardly utter a sentence or write a line without bringing in more or less of that same dialect. There is not an item of any tongue of which we know anything that is "natural" expression, or to the possession of which its speaker is brought by birth instead of by education; there is even very little that is traceably founded on such natural expression; everywhere θεύς or human attribution reigns supreme, and the original θέωs or natural significance has disappeared and been replaced by something else (as we have found it above). It seems to some as if a name like cuckoo (one of the most striking available cases of onomatopoeia) were a "natural" one; but there is just as much θεύς in it as in any other name; it implies the observation of an aggregate of qualities in a certain bird, and the selection of one among them as the convenient basis of a mutual understanding when the bird is in question; every animal conscious to us must have its designation, won in one way or another; and in this case to imitate the characteristic cry is the most available way. If anything but convenience and availability were involved, all our names for animals would have to be and remain imitations of the sounds they make. That the name of cuckoe is applicable also to the female and young, and at other than the singing season, and then to related species which do not make the same sound—all helps to show the essentially conventional character of even this name. An analogous process of elimination of original meaning, and reduction to the value of conventional designation merely, is to be seen in every part of language throughout its whole history. Since men ceased to derive their names from signs having a natural suggestiveness, and began to make them from other names already in use with an under-
stood value, every new name has had its etymology and its historical occasion—as, for example, the name quarantine from the Latin quarantena (quarantine days) or specie of commercial trade, or volume from its being rolled up, or book from a beech-
wood staff, or copper from Cyprus, or lunacy from a fancied influence of the moon, or priest from being an older (προσεχεσπός) person, or butterfly from the butter-yellow colour of a certain
common species: every part of our language, as of every other, is full of such examples—but, when once the name is applied, it belongs to that to which it is applied, and no longer to its relatives by etymology; its origin is neglected, and its form may be gradually changed beyond recognition, or its meaning so far altered that comparison with the original shall seem a joke or an absurdity. This is a regular and essential part of the process of name-making in all human speech, and from the very beginning of the history of speech: in fact (as pointed out above), the latter can only be said to have begun when this process was successfully initiated, when uttered signs began to be, what they have ever since continued to be, conventional, or dependent only on a mutual understanding. Thus alone did language gain the capacity of unlimited growth and development. The sphere and scope of natural expression are narrowly bounded; but there is no end to the resources of conventional sign-making.

It is evident that this change of the basis of men's communication from natural suggestiveness to mutual understanding, and the consequent purely conventional character of all human language, in its every part and particle, puts an absolute line of demarcation between the latter and the means of communication of all the lower animals. The two are not of the same kind, any more than human society in its variety of organization is of the same kind with the instinctive herding of wild cattle or swarming of insects, any more than human architecture with the instinctive burrowing of the former, the building of the bird, any more than human industry and accumulation of capital with the instinctive hoarding of bees and beavers. In all these cases alike the action of men is a result of the adaptation of means at hand to the satisfaction of felt needs, or of purposes dimly perceived at first, but growing clearer with gradually acquired experience. Man is the only being that has established institutions—gradually accumulated and perfected results of the exercise of powers analogous in kind to, but greatly differing in degree from, those of the lower animals. The difference in degree of endowment does not constitute the difference in language, it only leads to it. There was a time when all existing human beings were as destitute of language as the dog; and that time would come again for any number of human beings who should be cut off (if that were practicable) from all instruction by their fellows: only they would at once proceed to recreate language, society and arts by the same steps by which their own remote ancestors created those which we now possess; while the dog would remain what he and his ancestors have always been, a creature of very superior intelligence, indeed, as compared with most, of infinite intelligence as compared with many, yet incapable of rising by the acquisition of culture through the formation and development of traditional institutions. There is just the same salt in soil to be found in the difference between man's conventional speech and the natural communication of the lower races as in that between men's forms of society and the instinctive associations of the lower races; but it is no greater and no other; it is neither more absolute and characteristic nor more difficult to explain. Hence those who put forward language as the distinction between man and the lower animals, and those who look upon our language as the same in kind with the means of communication of the lower animals, only much more complete and perfect, fail alike to comprehend the true nature of language, and are alike wrong in their arguments and conclusions. No addition to or multiplication of brute speech would make anything of human speech; the two are separated by a step which no animal below man has ever taken; and, on the other hand, language is only the most conspicuous among those institutions the development of which has constituted human progress, while their possession constitutes human culture.

With the question of the origin of man, whether or not developed out of lower animal forms, intermediate to the anthropoid apes, language has nothing to do, nor can its study ever be made to contribute anything to the solution of that question. If there once existed creatures above the apes and below man, who were extirpated by primitive man as his especial rivals in the struggle for existence, or became extinct in any other way, there is no difficulty in supposing them to have possessed rudiments of human speech imperfect in many respects. At any rate, all existing human speech is one in the essential characteristics which we have thus far noted or shall hereafter have to consider, even as humanity is one in its distinction from the lower animals; the differences are in non-essentials. All speech is one in the sense that every human being, of whatever race he may be, is capable of acquiring any existing tongue, and of using it for the same purposes for which its present possessors use it, with such power and effect as his individual capacity allows, and without any essential change in the mental operations carried on by means of speech—even as he may acquire any other of the items of culture belonging to a race not his own.

The difference between employing one language and another is like that between employing one instrument and another in mechanical arts; one instrument may be better than another, and may enable its user to turn out better work, but the human ingenuity behind both is the same, and works in the same way.

Nor has the making of language anything whatever to do with making man what he is, as an animal species having a certain physical form and intellectual endowment. Being what he is by nature, man has by the development of language and other institutions become what he is by culture. His acquired culture is the necessary result of his native endowment, not the contrary. The acquisition of the first stumbling beginnings of a superior means of communication had no more influence to raise him from a simian to a human being than the present high culture and perfected speech of certain races has to lift them up to something more than human and specifically different from the races of inferior culture. It cannot be too absolutely laid down that differences of language, down to the possession of language at all, are differences only in respect to education and culture.

How long man, after he came into such being as he now is, physically and intellectually, continued to communicate with imitative signs of direct significance, when the production of traditional signs began, how rapidly they were accumulated, and how long any traces of their imitative origin clave to them—these and the like questions it is at present idle to try to answer even conjecturally: just as it is to seek to determine when the first instruments were used, how soon they were shaped instead of being left crude, at what epoch fire was reduced to service, and so on. The stages of development and their succession are clear enough; to fix their chronology will doubtless never be found practicable. There is much reason for holding, as some do, that the very first items of culture were hardest to win and cost most time, the rate of accumulation (as in the case of capital) increasing with the amount accumulated. Beyond all reasonable question, however, there was a positively long period of purely imitative signs, and a longer one of mixed imitative and traditional ones, the latter gradually gaining upon the former, before the present condition of things was reached, when the production of new signs by imitation is only sporadic and of the utmost rarity, and all language-signs besides are traditional, their increase in any community being solely by variation and combination, and by borrowing from other communities.

Of what nature, in various respects, this earliest language-material was is sufficiently clear. The signs, in the first place, were more of the word than of the "root." By this is meant only that they were integral signs, significant in their entirety, not divisible into parts, of which one signified one thing and another another thing, or of which one gave the main significance, while another was an added sign of kind or relation. In a language of developed structure like our own, we arrive at such "roots" mainly by an artificial stripping-off of the signs of relation which almost every word still has, or can be shown to have once had. In un-cost-li-ness, for example, cost is the centrally significant element; so far as English is
concerned it is a root, about which cluster a whole body of forms and derivatives; if we could follow its history no farther it would be to us an ultimate root, as much so as bind or sing or mean. But we can follow it up, to the Latin compound con-sta, a root sta with a prefixed formative element con. Then sta, which in slightly varied forms we find in a whole body of related tongues called "Indo-European," having in them all the same significance "stand," is an Indo-European root, and to us an ultimate one, because we can follow its history no farther; but there always remains the possibility that it is as far from being actually original as is the English root cost: that is to say, it is not within our power ever to get back to the really primitive elements of speech and to demonstrate their character by positive evidence. The reason for accepting a primitive root-stage of language is in great part theoretical: because nothing else is reconcilable with any acceptable view of the origin of language. The law of the simplicity of beginnings is an absolute one for everything of the nature of an institution, for every gradually developed product of the exercise of human faculties. That an original speech-sign should be of double character, one part of it meaning this and another part that, or one part radical and the other formative, is as inconceivable as that the first instruments should be made of handles, as if the first shelves, a front room and a back one. But this theoretical reason finds all the historical support which it needs in the fact that, through all the observable periods of language-history we see formative elements coming from words originally independent, and not from anything else. Thus, in the example just taken, the -i of costliness is a suffix of so recent growth that its whole history is distinctly traceable; it is simply our adjective like, worn down in both form and meaning to a subordinate value in combination with certain words to which it was appended, and then added freely as a suffix to any word from which it was desired to make a derivative adjective—or, later but more often, a derivative adverb. The roots is much older (though only Germanic), and its history obscurer; it contains, in fact, two parts, neither of them of demonstrable origin; but there are equivalent later suffixes, as ship in hardship and dom in wisdom, whose derivation from independent words (shape, doom) is beyond question. The un- of uncostliness is still more ancient (being Indo-European), and its probably pronominal origin hardly available as an illustration; but the comparatively modern prefix be-, of become, belte, &c., comes from the independent preposition by, by the same process as -ly or -li from like. And the con which has contributed its part to the making of the quasi-root cost is also in origin identical with the Latin preposition cum, "with." By all the known facts of later language-growth we are driven to the opinion that the differentation of the root-stage is not a previous existing independent word; and hence that in analysing our present words we are retracing the steps of an earlier synthesis, or following up the history of our formed words toward the uniformed roots out of which they have grown. The doctrine of the historical growth of language-structure leads by a logical necessity to that of a root-stage in the history of all language; the only means of avoiding the latter is the assumption of a miraculous element in the former.

Of what phonetic form were the earliest traditional speech-signs, is, so far as essentials are concerned, to be inferred with reasonable certainty. They were doubtless articulate: that is to say, composed of alternating consonant and vowel sounds, like our present speech; and they probably contained a part of the same sounds which we now use. All human language is of this character; there are no sounds in any tongue which are not learned and reproduced as easily by children of one race as of another; all dialects admit a like phonetic analysis, and are representable by alphabetic signs; and the leading sounds, consonant and vowel, are even practically the same in all; though every dialect has its own (for the most part, readily definable and imitable) niceties of their pronunciation, while certain sounds are rare, or even met with only in a single group of languages or in a single language. Articulate sounds are such as are capable of being combined with others into that succession of distinct yet connectable syllables which is the characteristic of human speech-utterance. The name "articulate" belongs to this utterance, as distinguished from inarticulate human sounds and cries and from the sounds made by the lower animals. The word itself is Latin, by translation from the Greek, and, though very widely misunderstood, and even deliberately misapplied in some languages to designate all sound, of whatever kind, uttered by any living creature, is a most happily chosen and truly descriptive term. It signifies 'jointed,' or broken up into successive parts, like a limb or stem; the joints are the syllables; and the syllable structure is mainly effected by the alternation of vowels or consonant sounds with opener or vowel sounds. The simplest syllabic combination (as the facts of language show) is that of a single consonant with a following vowel; and there are languages even now existing which reject any other. Hence there is much plausibility in the view that the first speech-signs will have had this phonetic form and been monosyllabic, or disyllabic only by repetition (reduplication) of one syllable, such as the speech of very young children shows to have a peculiar ease and naturalness. The point, however, is one of only secondary importance, and may be left to the further progress of philology to study, if it can; the root-theory, of whatever rate, is not bound to any definite form or extent of root, but only denies that there can have been any grammatical structure in language except by development in connexion with experience in the use of language. What particular sounds, and how many, made up the first spoken alphabet is also a matter of conjecture merely; they are likely to have been the closest consonants and the openest vowels, medial utterances being of later development.

As regards their significant value, the first language-signs must have denoted those physical acts and qualities which are directly apprehensible by the senses; both because these alone are directly significant, and because it was only they that untrained human beings had at the power to deal with or the occasion to use. Such signs would then be applied to more intellectual uses as fast as there was occasion for it. The whole history of language, down to our own day, is full of examples of the reduction of physical terms and phrases to the expression of non-physical conceptions and relations; we can hardly write a line without giving illustrations of this kind of linguistic growth. So pervading is it, that we never regard ourselves as having read the history—of any intellectual or moral term till we have traced it back to a physical origin. And we are still all the time drawing figurative comparisons between material and moral things and processes, and calling the latter by the names of the former. In this business of developing speech—forms, that is, we are perfectly at home and have never had any difficulty in providing for new knowledge and more refined thought by putting to new uses the earlier and grosser materials of speech.

As a matter of course, whatever we now signify by our simple expressions for simple acts, wants, and the like, was intended to be signified through the first speech-signs by the users of them. But to us, with our elaborated apparatus of speech, the sentence, composed of subject and predicate, with a verb or special predicative word to signify the predication, is established as the norm of expression, and we regard everything else as an abbreviated sentence, or as involving a virtual sentence. With a view to this we must have "parts of speech": that is, words held apart in office from one another, each usable for such and such a purpose and no other, and answering a due variety of purposes, so that when they are combined they fit together, as parts composing a whole, and the desired meaning is made clear. Inflections, too, lend their aid; or else auxiliary words of various kinds answering the same purpose—namely, of determining the relations of the members of the sentence. But all our success in understanding the earliest stages of language depends upon our power to conceive a state of things where none of these distinctions were established, where one speech-sign was like another, calling up a conception in its indefinite entirety, and leaving the circumstances of the ease to limit its application.
Such a language is far below ours in explicitness; but it would suffice for a great deal of successful communication; indeed (as will be shown farther on) there are many languages even now in existence which, to many little better than a knowledge of a vocabulary, a gesture of beckoning or repulsion, a grunt of assent or inquiry, is as significant as a sentence, means a sentence, is translatable into a sentence, and hence may even in a certain way be called a sentence; and in the same way, but only so, the original roots of language may be said to have been sentences.

In point of fact, between the holophrastic gesture or uttered sign and the sentence which we can now substitute for it—for example between the sign of beckoning and the equivalent sentence, "I want you to come here"—lies the whole history of development of expressive speech.

What has been this history of development, how the first scanty and formless signs have been changed into the immense variety and fullness of existing speech, it is of course impossible to point out in detail, or by demonstration of facts, because nearly the whole process is hidden in the darkness of an impenetrable past. The only way to cast any light upon it is by careful induction from the change and growth which are seen to have been going on in the recent periods for which we have recorded evidence, or which are going on at the present time. Of some groups of related languages we can read the life for three or four thousand years back, and by comparison can infer it much farther; and the knowledge thus won is what we have to apply to the explanation of periods and languages otherwise unknown. Nothing has a right to be admitted as a factor in language-growth of which the action is not demonstrable in recorded language. Our own family of languages is the one of whose development most is known, by observation and well-warranted inference; and it may be well here to sketch the most important features of its history, by way of general illustration.

Appareently the earliest class-distinction traceable in Indo-European speech is that of pronominal roots, or signs of position, from the more general mass of roots. It is not a formal distinction, marked by a structural difference, but, so far as can be seen, is founded only on the assignment by usage of certain elements to certain offices. Formal distinction began with combination, the addition of one element to another, their fusion into a single word, and the reduction of the one part to a subordinate value, as sign of a certain modification of meaning of the other. Thus, doubtless by endings of pronominal origin, were made the first verb-forms, or words used only when predication was intended (since that is all that makes a verb), conveying at first a distinction of persons only, then of persons and numbers, while the further distinctions of tense and mode were by degrees added. To the nouns, which became nouns by the setting up of the separate and special class of verbs, were added in like manner distinctions of case, of number, and of gender. With the separation of noun and verb, and the establishment of their respective inflexion, the creative work of language-making is virtually done; the rest is a matter of differentiation of uses. For the noun (noun substantive) and the adjective (noun adjective) become two parts of speech only by a gradually deepened separation of use; there is no original or formal distinction between them; the pronouns as a rule merely add the noun-inflexion to a special set of stems; adverbs are a part of the same formation as nouns; prepositions are adverbs with a specialized construction, of secondary growth; conjunctions are the products of a like specialization; articles, where found at all, are merely weakened demonstratives and numerals.

To the process of form-making, as exhibited in this history, belong two parts: the one external, consisting in the addition of one existing element of speech to another and their combination into a single word; the other internal, consisting in the adaptation of the compound to its special use and involving the subordination of one element to the other. Both parts appear also abundantly in other departments of language-change, and throughout the whole history of our languages; nothing has to be assumed for the earliest formations which is not plainly illustrated in the latest. For example, the last important addition to the formative elements of English is the opposition, adverb-making suffix -ly, coming, as already pointed out, from the independent adjective like. There was nothing at first to distinguish a compound like godly (godlike) from one like storm-tossed, save that the former was more adaptable than the other to wider uses; resemblance is an idea easily generalized into apperance and the like, and the conversion of godly to godly is a simple result of the processes of phonetic change described farther on. The extension of the same element to combination with adjectives instead of nouns, and its conversion to adverb-making value, is a much more striking case of adaptation, and is nearly limited to English among the Germanic languages that have turned like into a suffix. A similar striking case of combination and adaptation is seen in the Romanic adverb-making suffix mente or ment, coming from the Latin ablative mente, "with mind." So, to make a Romanic future like donnerai, "I shall give," there was needed in the first place the pre-existing elements, donner, "to give," and ai, "I have," and their combination; but this is only a part; the other indispensable part is the gradual adaptation of a phrase meaning "I have [something before me] for giving" to the expression of simple futurity, donabo. So far as the adaptation is concerned the case is quite parallel to that of fa! don\'t, "I have given," &c. (equivalent phrases or combinations are found in many languages), where the expression of possession of something that is acted on has been in like manner modified into the expression of past action. Parallel in both combination and adaptation is the past tense loved, according to a widely accepted theory, from love-did, while we have again the same adaptation without combination in the equivalent phrase did love.

That these are examples of the process by which the whole inflective structure of Indian-European language was built up admits of no reasonable question. Our belief that it is so rests upon the solid foundation that we can demonstrate no other process, and that this one is sufficient. It is true that we can prove such an origin for our formative elements in only a small minority of instances; but this is just what was to be expected, considering what we know of the disguising processes of language-growth. No one would guess in the mere y of ably (for able-ly) the presence of the adjective like, any more than in the altered final of sent and the shortened vowel of led the effect of a did once added to send and lead. The true history of these forms can be shown, because there happen to be other facts left in existence to show it; where such facts are not within reach we are left to infer by analogy from the known to the unknown. The validity of our inference can only be shaken by showing that there are forms incapable of having been made in this way, or that there are and have been other ways of making forms. Of the former there is evidently but small chance; if a noun-forming "with mind" can become the means of conversion of all the adjectives of a language into adverbs, and a verb meaning "have" (and, yet earlier, "seize") of signifying both future and past time, there is obviously nothing that is impossible of attainment by such means. As regards the latter, no one appears to have even attempted to demonstrate the genesis of formative elements in any other way during the historical periods of language; it is simply assumed that the early methods of language-making will have been something different from and superior in spontaneity and fruitfulness to the later ones; that certain forms, or forms at certain periods, were made out-and-out, as forms; that signification and distinction were ever so connected; thus, in word and form; that original words were many-membered; and that a formative value settled in some member of them—and the like. Such doctrines are purely fanciful, and so opposed to the teachings both of observation and of sound theory that the epiphet absurd is hardly too strong to apply to them. If the latter races, of developed intelligence, and trained in the methods of fuller expression, can only win a new form by a long and gradual process of combination and adaptation, why should the earlier and comparatively untrained generations have been able to do any
The advantage ought to be, if anywhere, on our side. The progress of language in every department, accompanying and representing the advance of the race, on the whole, in the art of speaking as in other arts, is from the grosser to the more refined, from the physical to the moral and intellectual, from the material to the formal. The conversion of compounding into form, the reduction of one of their elements to formative, is simply a part of the general process which also creates auxiliaries and form-words and connectives, all the vocabulary of mind, and all the figurative phraseology that gives life and vigour to our speech. If a copula, expressive of the grammatical relation of predication, could be won only by attenuation of the meaning of verbs signifying " grow," " breathe," " stand," and the like; if our auxiliaries of tense and mode all go traceably back to words of physical meaning (as have to " seize," may to " be great or strong," shall to " be under penalty," and so on); if of comes from the comparatively physical off, and for from " before, forward;" if relative pronouns are specialized demonstratives and interrogatives; if right means etymologically " straight," and wrong means " twisted;" if spirit is " blowing," and intellect a " picking out among," and understanding a " getting beneath," and development an " unfolding;" if an event takes place or comes to pass, and then drops out of mind and is forgotten (opposite of gotten)—then it is of no avail to object to the grossness of any of the processes by which, in earlier language or in later, the expression of formal relations is won. The mental sense of the relation expressed is entirely superior to and independent of the means of its expression. He who, to express the plural of men, says what is equivalent to man-man or heap-man (devices which are met with in not a few languages) has just as good a sense of plurality as he who says men or homines; that sense is no more degraded in him by the coarseness of the phrase he uses to signify it than is our own sense of eventuality and of pastness by the undisguised coarseness of take place and have been. In short, it is to be laid down with the utmost distinctness and confidence, as a law of language-growth, that there is nothing formal anywhere in language which was not once material; that the formal is made out of the material, by processes which began in the earliest history of language and are still in action.

We have dropped here the restriction to our own or Indo-European languages, with which we began, because it is evident that what is true of this family of speech, one of the two most highly organized that exist, may also be true of the rest—must be true of them, unless some valid evidence be found to the contrary. The unity of human nature makes human speech alike in the character of its beginnings and in the general features of its after-history. Everywhere among men a certain store of expression, body of traditional signs of thought, being given, as used by a certain community, it is capable of increase on certain accordant lines, and only on them. In some languages, and under peculiar circumstances, borrowing is a great means of increase; but it is the most external and least organically important of all. Out-and-out invention (which, so far as we can see, must be of the kind called by us onomatopoetic) is found to play only a very insignificant part in the historical periods of language—clearly because there are other and easier modes of gaining new expression for what needs to be expressed. In the course of phonetic change a word sometimes varies into two (or more) forms, and makes so many words, which are differently turned to account. Everything beyond this must be the product of combination; there is no other way, so far as concerns the externals of speech. Then, partly as accompanying and aiding this external growth, partly as separate from and supplementing it, there is in all language an internal growth, making no appearance in the audible part of speech, consisting in multiplication of meanings, the abbreviation of the element in preference to the moral and intellectual, the restriction of words to certain uses, and so on. Along with these, too, a constant change of phonetic form constitutes an inseparable part of the life of language. Speech is no more stable with respect to the sounds of which it is composed than with respect to its grammatical forms, its vocabulary, or the body of conceptions signified by it. Even nearly related languages differ as much in their spoken alphabets and the combinations of sounds they admit, and in their uttered forms of words historically the same, as in any other part; and the same is true of local dialects and of class dialects within the same community. Phonetic change and growth is a matter of the processes of the mind, as are the product of wholly independent tendencies. Sometimes, indeed, they chance to coincide, as in the distinction of minute " small," and minute " moment;" but it is only by chance, as the spoken accordance of second in its two meanings (" next" and "sixtieth of a minute") shows; words that maintain their identity of value most obstinately, like the numerals, are liable to vary indefinitely in form (so four, fddor, quaatar, τωδώρος, &c., from an original kwteor-; five, quinquæ, τέτρα, coic, &c., from pentakw—while, on the other hand, two and three show as striking an accordance of form as of meaning through all the same languages); what is far the most common is that the word becomes very unlike its former self in both respects, like priest from the Greek πρεσβύτερος (presbyter), literally " older man."

Human convenience is, to be sure, the governing motive in both changes; but it is convenience of two different kinds: the one mental, depending on the fact (pointed out above) that a name when once applied belongs to the thing to which it is applied, to the disregard of its etymological connexions, does not need to be changed when the thing changes, and is ready for new application to anything that can be brought into one class with the latter; and the other physical, depending on the organs of speech and their successive movements, by which the sounds that make up the word are produced. Phonetic convenience is the economy of effort on the part of those organs; and to no other law than that of economy of utterance have any of the phenomena of phonetic change been found traceable (though it is also to be noted that some phenomena have not hitherto been successfully brought under it, and that the effect of expressing this is still unclear). “ Euphony,” which was used to be appealed to as explanation, is a false principle, except so far as the term may be made an idealized synonym of economy. The ear finds that agreeable which the organs of utterance find facil. Economy in utterance is no isolated tendency; it is the same that plays its part in all other kinds of human action, and in language appears equally in the abbreviation of the sentence by leaving out parts that can be spared without loss of intelligibility. It is an economy of effort, always lying in wait, like gravitation, to pull down what is not sufficiently held up—the holding-up force in language being the faithfulness of tradition, or accurate reproduction by the learner and user of the signs which he has acquired. No generation of men has any intention to speak otherwise than as its predecessor has spoken, or any consciousness that it is doing so; and yet, from generation to generation, words are shortened, sounds are assimilated to one another, and one element passes out of use while a new one is introduced. Abbreviation and assimilation are the most conspicuous departments of phonetic change, and those in which the nature of the governing tendency is most plainly seen. Taken by itself, one sound is as easy as another to the person who has accustomed himself to it from childhood; and those which the young child most easily acquires are not those which in the history of speech are least liable to alteration; it is especially in the combinations and transitions of rapid speaking that the tongue, as it were, finds out for itself easier ways of performing its task, by dropping and slurring and adapting. To trace out the infinitely varied items of this change, to co-ordinate and compare them and discover their reasons, constitutes a special department of language-study, which is treated under the head of Phonetics. It only needs to be pointed out here that phonetic change plays a necessary part in the structural development of language, by integrating compound words through fusion and loss of identity of their component parts, and, what is of yet more importance, by converting them into forms, through disguise of identity of one of the parts and its phonetic subordination to the other part. It is this that turns, for example, the compound god-like into
the derivative godly, the compound love-did into the verbal form loved. And yet one further result sometimes follows: an internal change is wrought by phonetic influence in the body of a word, which change then may in the further history of the word be left as the sole means of distinction between one form and another. It is thus that, in the most recent period, the distinction of led from met and met from meet and so on has been made; the added auxiliary which originally made these pretenses induced a shortening of the root-vowel, and this was left behind when the auxiliary disappeared by the usual process of abbreviation. It is in the same way that the distinctions of men from man, of were from was, of set from sit, with all their analogues, were brought about: by a modification of vowel-sound (Ger. Umlaut) occasioned by the presence in the following syllable of an i-vowel, which in the older stages of the language is still to be seen there. And the distinctions of sing, sang, sung and song, of bind, bound, band and bond, are certainly of the same kind, though they go back so far in the history of our family of languages that their beginnings are not yet clearly demonstrable; they were in their origin phonetic accidents, inorganic, mere accompaniments and results of external conditions which bore the office of distinction of meaning and were sufficient to it; in some of our languages they have been disregarded and effaced, in others they have risen to prominent importance. To regard these internal changes as primary and organic is parallel with assuming the primariness of the formative apparatus of language in general; like this, it ignores the positive evidence we have of the secondary production of such differences; they are, like everything else in linguistic structure, the outcome of combination and adaptation. Borrowing, or the taking-in of material out of another language, has been more than once referred to above as sometimes an important element in language-history, though less deep-reaching and organic than the rest. There is nothing anomalous about borrowing; it is rather in essential accordance with the whole process of language-acquisition. All our names were adopted by us because they were already in use by others; and a community is in the same way capable of taking a new name from a community with which it comes in contact as an individual from individuals. Not that it seeks or admits in this way new names for old things; but it accepts new things along with the names that seem to belong to them. Hence any degree of intercourse between one community and another, leading to exchange of products or of knowledge, is sure to lead also to some borrowing of names; and there is hardly a language in the world, except of races in peculiarly isolated positions, that does not contain a certain amount of foreign material thus won, even as our English has elements in its vocabulary from half the other tongues in the world. The scale of borrowing is greatly increased when one people becomes the pupil of another in respect of its civilization: hence the abundant classical elements in all the European tongues, even the non-Romanic; hence the Arabic material in Persian and Turkish and Malay; hence the Chinese in Japanese and Corean; and, as a further result, even dead languages, like the Greek and Latin and the Sanskrit, become stores to be drawn upon in that learned and conscious quest of new expression which is the body of culture of all nations. Indeed, no measure replaces the unconscious growth of natural speech. So, in mixture of communities, which is a highly-intensified form of contact and intercourse, there follows such mixture of speech as the conditions of the case determine; yet not a mixture on equal terms, through all the departments of vocabulary and grammar; the resulting speech (just as when two individuals learn to speak alike) is essentially that of the one constituent of the new community, with more or less material borrowed from that of the other. What is most easily taken in out of another language is the names of concrete things; every degree of removal from this involves additional difficulty—names of abstract things, for the understanding of which a coupling of forms in the highest sense, or forms of inflexion, is well-nigh or quite impossible; no example of it has been demonstrated in any of the historical periods of language, though it is sometimes adventurously assumed as a part of prehistoric growth. How nearly it may be approached is instanced by the presence in English of such learned plurals as phænomena and strata. This extreme resistance to mixture in the department of inflexion is the ground on which some deny the possibility of mixture in language, and hence the existence of such a thing as a mixed language. The difference is mainly a verbal one; but it would characterize as real and...
Every beginning of its traditional life, is liable; the only growth is internal, by that multiplication and adaptation and improvement of meanings which is equally an inseparable part of all language-history. This may include the reduction of certain elements to the value of auxiliaries, particles, form-words, such as play an important part in analytical tongues like English, and are perhaps also instanced in historic Indo-European speech by the class of pronominal roots. Phrases take the place of compounds and of inflexions, and the same element may have an auxiliary value in certain combinations while retaining its full force in others, like, for instance, our own have. It is not easy to define the distinction between such phrase-collocations and the beginnings of agglutination; yet the distinction itself is in general clearly enough to be drawn (like that in French between donner and ai donné) when the whole habit of the language is well understood.

Such languages, constituting the small minority of human tongues, are wont to be called "isolating," i.e. using each element by itself, in its integral form. All besides are "agglutinative," or more or less compounded into words containing a formal part, an indicator of class-value. Here the differences, in kind and degree, are very great; the variety ranges from a scantiness hardly superior to Chinese isolation up to an intricacy compared with which Indo-European structure is hardly fuller than Chinese. Some brief characterization of the various families of language in this respect will be given farther on, in connexion with their classification. The attempt is also made to classify the great mass of agglutinating tongues under different heads: those are ranked as simply "agglutinative" in which there is a general conservation of the separate identity of root or stem on the one hand, and of formative element, suffix or prefix, on the other; while the name "indefective," used in a higher and pregnant sense, is given to those that admit a superior fusion and integration of the two parts, to the disguise and loss of separate identity, and, yet more, with the development of an internal change as auxiliary to or as substitute for the original agglutination. But there is no term in linguistic science so uncertain of meaning, so arbitrary of application, so dependent on the idiosyncrasy of its user, as the term "indefective." Any language ought to have the right to be called indefective that has inflexion: that is, that not merely distinguishes parts of speech by root and stem; that it does not limit itself to the simple alliance of root and prefix, but also conjugates its verbs and declines its nouns; and the name is sometimes so used. If, again, it be strictly limited to signify the possession of inner flexion of roots and stems (as if simply agglutinated forms could be called "indefective"), it marks only a difference of degree of agglutination, and should be carefully used as so doing. As describing the fundamental and predominant character of language-structure, it belongs to only one family of languages, the Semitic, where most of the work of grammatical distinction is done by internal changes of vowel, the origin of which thus far eludes all attempts at explanation. By perhaps the majority of students of language it is, as a generally descriptive title, restricted to that family and none other. In our finds of language-structure it is not to be approved, for, in respect to this characteristic, Indo-European speech ranks not with Semitic but with the great body of agglutinative tongues. To few of these can the name be altogether denied, since there is hardly a body of related dialects in existence that does not exhibit some items of "indefective" structure; the Aryan is only the one among them that has most to show. Outside the Semitic, at any rate, one should not speak of indefinite and non-indefinite languages, but only of languages more indefinite and less indefective.

To account for the great and striking differences of structure among human languages is beyond the power of the linguistic student. He has no data on which to build a table of the influence of historical events on language, and the mere possibility is enough to exclude all dogmatic assertion of the unity of origin of human speech, even assuming unity of origin of the human race. For to prove that identity by the still existing facts of language is utterly out of the question;
the metamorphosing effect of constant change has been too
great to allow it. In point of fact, taking languages as they
now exist, only those have been shown related which possess
a common structure, or have together grown out of the more
primitive radical stage, since structure proves itself a more
constant and reliable evidence than material. And this is
likely ever to be the case; at any rate, to trace all the world's
languages so far back toward their beginnings as to find in them
evidences of identity is beyond the wildest hope. We must
be content with demonstrating for those beginnings a unity of
kind as alike a body of formless roots. But, on the other hand,
since this unity is really demonstrated, since all structure is
the result of growth, and no degree of difference of structure,
any more than a degree of difference of production as the
result of discordant growth from identical beginnings, it is
equally inadmissible to claim that the diversities of language
prove it to have had different beginnings. That is to say, the
question of the unity of speech, and yet more that of the unity
of the race, is beyond the reach of the student of language;
the best view he can attain is the hypothetical one, that, if
the race is one, the beginnings of speech were perhaps one—but
probably not, even then. This negative conclusion is
so clearly established as to leave no excuse for the still oft-
repeated attempts to press language into service on either side
of the controversy respecting human unity of race.

That making and changing of language is by the act of
its speakers is too obvious to call for discussion. No other
force capable of acting and of producing effects is
either demonstrable or conceivable as concerned
in the work. The doctrine that language is an
organism, growing by its own inherent powers,
exempt from the interference of those who use it, is simply
an indefensible paradox. Every word that is uttered is so
by an act of human will, at first in imitation of others, then
more and more by a formed and controlling habit; it is acces-
sible to no change except by influences working in the speaker's
mind and leading him to make it otherwise. Not that he is
aware of this, or directs his action knowingly to that end.
The whole process is unconscious. If any implication of reflective
or intended action can be shown to inhere in any doctrine of
linguistic science, it vitiates that doctrine. The attitude of the
ordinary speaker towards his language is that of unreasoning
acceptance; it seems to him that his names for things are
their real names, and all others unintelligible nicknames; he
thinks himself to possess his speech by the same tenure as his
sight or hearing; it is "natural" to him (or, if he reasons about it,
he attributes it to a divine origin, as races beginning to
philosophize have been wont to ascribe their various social institutions
to their gods); he knows nothing of its structure and relations;
it never occurs to him to find fault with it, or to deem it insuf-
cient and add to or change it; he is wholly unaware that it
does change. He simply satisfies his social needs of commu-
nication by means of it; and if he has anything to express that
is different from what has been expressed before, he takes the
shortest way to a provision for the need; while any relaxation
of the energy of utterance tends to a variation in the uttered
combinations; and thus changes come by his act, though with-
out his knowledge. His sole object is, on the basis of what
language he has, to make known his thought in the most con-
vienent way to his fellow; everything else follows with and
from that. Human nature and circumstances being what they
are, what follows actually is, as already shown, incessant
growth and change. For it we have not to seek special distur-
bng causes in the history of the speakers, although such may
come in to heighten and quicken the change; we know that
even in a small community, on a narrow islet, cut off from all
intercourse with other communities, the speech would grow
different—as certainly, if not as rapidly, as anywhere in the
world—and only by the action of its speakers: not that the
speakers of a language act in unison and simultaneously to
produce a given change. This must begin in an individual,
or more or less accordantly in a limited number of individuals,
and spread from such example through the community. Initia-
tion by one or a few, acceptance and adoption by the rest—
such is the necessary method of all linguistic change, and to be
read as plainly in the facts of change now going on among our-
ourselves as in those of former language. The doctrine of the
inaccessibility of language to other action than that of its
speakers does not imply a power in the individual speaker to
create or alter anything in the common speech, any more than
it implies his desire to do so. What he suggests by his example
must be approved by the invitation of his fellows, in order to
become language. The common speech is the common prop-
erty, and no one person has any more power over it than
any other, if there, for example, a thousand speakers of a
certain dialect, each one yields in general a thousandth part of
the force required to change it—with just so much more as may
belong to his excess of influence over his fellows, due to recog-
nized superiority of any kind on his part. His action is limited
only by their assent; but this is in effect a very narrow limita-
tion, ensuring the adoption of nothing that is not in near accor-
dance with the already existing; though it also is to be noted
that he is as little apt to strike off into startling change as they
to allow it; since the governing power of already formed habits
of speech is as strong in him as in them. That change to which
the existing habits naturally lead is easy to bring about; any
other is practically impossible. It is this tendency on the part
of the collective speakers of a language to approve or
reject a proposed change according to its conformity with
their already subsisting usages that we are accustomed to call
by the fanciful name "the genius of a language."

On the relation of the part played in language-change by
the individual to that by the community, in combination with
the inevitability of change, rests the explanation of
the dialectic variation of language. If language were
stable there would of course be no divarication; but
since it is always varying, and by items of difference that proceed
from individuals and become general by diffusion, there can be
uniformity of change only so far as diffusion goes or as the
influences of communication extend. Within the limits of a
single community, small or large, whatever change arises spreads
gradually to all, and so becomes part of the general speech;
but let that community become divided into two (or more)
parts, and then the changes arising in either part do not spread
to the other, and there begins to appear a difference in linguistic
usage between them. It is at first slight, even to insignificance;
not greater than exists between the dialects of different localities
or ranks or occupations in the same community, without detri-
ment to the general unity of speech. This unity, namely, rests
solely on mutual intelligibility, and is compatible with no
small amount of individual and class difference, in vocabulary,
in grammar and in pronunciation; indeed, in the strictest
sense, each individual has a dialect of his own, different from
that of every other, even as he has a handwriting, a countenance,
a character of his own. And every item of change, as it takes
place, must have its season of existence as a local or class
or trade peculiarity, before it gains universal currency; some of
them linger long in that condition, or never emerge from it.
All these differences in the speech of different sub-communities
within the same community are essentially dialectic; they differ
not in kind, but only in degree, from those which separate the
best-marked dialects; they are kept down by general communi-
cation within the limit of general mutual intelligibility. Where
that restraining influence ceases the limit is gradually but
surely overpassed, and real dialects are the result. From
what we know of the life of language we can say positively
that continued uniformity of speech without continued com-
munity is not practicable. If it were possible to divide
artificially, by an impassable chasm or wall, a people one for
ages, and continuing to occupy the same seats, the language
of the divided parts would at once begin to be dialectically
different; and after sufficient time had elapsed each would have
become unintelligible to the other. That is to say, whenever
a community of uniform speech breaks up, its speech breaks

PHILOLOGY

424
up also; nor do we know of any other cause of dialectic diversity.

In applying this explanation of dialectic growth we have to allow for modifying circumstances of various nature, which alter not indeed the fact but the rate and kind of divarication. Some languages grow and change much more rapidly than others, with a corresponding effect upon divarication, since this is but a result of discordant growth. Usually, when there is division of a community, the parts get into different external circumstances, come in contact or mingle with different neighbouring communities, and the like; and this quickens and increases their divergence of speech. But the modifying factor of by far the highest importance here, as elsewhere in the history of language, is civilization. Civilization in its higher forms so multiplies the forces of communication as to render it possible that the widely-divided parts of one people, living in circumstances and under institutions of very different character, should yet maintain a substantial oneness of speech; of this there is no more striking example than the two great divisions of the English-speaking people on opposite sides of the Atlantic. On the other hand, a savage people cannot spread even a little without dialectic disunity; there are abundant examples to be met with now of mutually unintelligible speech between the smallest subdivisions of a race of obviously kindred tongue—as the different clusters of huts on the same coral islet. It is with linguistic unity precisely as it is with political unity, and for the same reasons. Before the attainment of civilization the human race, whether proceeding from one centre of dispersion or from several, was spread over the earth in a state of utter disintegration; but every centre of civilization becomes also a centre of integration; its influences make for unity of speech as of all other social institutions. Since culture has become a paramount and the dominant power in human history, the unifying forces in language have also been stronger than the diversifying; and with culture at its full height, and spread equally to every land and race, one universal language, like one universal community, is not an absurdity or theoretic impossibility, but only a Utopian or millennial dream.

Dialectic variation is thus simply a consequence of the movements of population. As the original human race or races, so the divisions or communities of later formation, from point to point through the whole life of man on the earth, have spread and separated, but jostled and interfered, have conquered and exterminated or mingled and absorbed; and then, when the language is free from all external pressure, the divergencies of these movements can be read in the present condition of languages, as in a faithful though obscure record—more, doubtless, than can be read in any other way, however little it may be when viewed absolutely. Dialectic resemblances point inevitably back to an earlier unity of speech, and hence of community; from what we know of the history of speech, they are not to be accounted for in any other way. The longer the separation that has produced the diversity, the greater its degree. With every generation the amount of accordance decreases and that of discordance increases the common origin of the dialects is at first palpable, then evident on examination, till the trace to be made out by laborious research, then perhaps no longer demonstrable at all; for there is plainly no limit to the possible divergence. So long, now, as any evidence of original unity is discoverable we call the languages "related dialects," and combine them into a "family." The term "family" simply signifies a group of languages which the evidence thus far at command, as estimated by us, leads us to regard as descended by the ordinary processes of dialectic divarication from one original tongue. That it does not imply a denial of the possibility of wider relationship is obvious from what has been said above. That there is abundant room for error in the classification represented by it is also clear, since we may take purely accidental resemblances, or the results of borrowing, for evidence of common descent, or may overlook or wrongly estimate real evidences, which more study and improved method will bring to light.

Grouping into families is nothing more than the best classification attainable at a given stage in the progress of linguistic science; it is in no small part provisional only, and is always held liable to modification, even sweeping, by the results of further research. Of some families we can follow the history by external evidences a great way back into the past; their structure is so highly developed as to be traced with confidence everywhere; and their territory is well within our reach: such we regard with the highest degree of confidence, hardly allowing for more than the possibility that some other dialect, or group, or now-accepted family even, may sometime prove its right to be added on. But these are the rare exceptions; in the great majority of cases we have only the languages as they now exist, and in more or less scanty collections, of every degree of trustworthiness; and even their first grouping is tentative and incomplete, and involves an adjournment of deeper questions to the day of more light. To complete and perfect the work of classification by relationship, or the establishment of families and their subdivisions, is the first object of the comparative study of languages. No other classification has a place in the least comparable with it; that by grade of structure is a mere recreation, leading to nothing; that by absolute worth is of no account whatever, at any rate in the present state of our knowledge. On genetic relationship, in the first place, is founded all investigation of the historical development of languages; since it is in the main the comparison of related dialects, even in the case of families having a long recorded history, and elsewhere only that, that gives us knowledge of their earlier condition and enables us to trace the lines of change. In the second place, and yet more obviously, with this classification is connected all that language has to teach us; and the affinities of human races; whatever aid linguistic science renders to ethnology rests upon the proved relationships of human tongues.

That a classification of languages, to which we have now to proceed, is not equivalent to a classification of races, and why this is so, is evident enough from the principles which have been brought out by our whole discussion of languages, and which, in their bearing upon this particular point, may well be recapitulated here. No language is a race-characteristic, determined by the special endowments of a race; all languages are of the nature of institutions, parallel products of powers common to all mankind and the powers, namely, involved in the application of the fittest available means to the end of communication. Hence they are indefinitely transferable, like other institutions—like religions, arts, forms of social organization, and so on—under the constraining force of circumstances. As an individual can learn any language, foreign as well as ancestral, if he be put in his way, so also a community, which in respect to such a matter is only an aggregate of individuals. Accordingly, as individuals of very various race are often found in one community, speaking together one tongue, and utterly ignorant of any other, so there are found great communities of various descent, speaking the dialects of one common tongue, which at some period historical circumstances have made them one, and which emerge into every one's mind when this subject is discussed, is that of the Romanic countries of southern Europe, all using dialects of a language which, 2500 years ago, was itself the insignificant dialect of a small district in central Italy; but this is only the most important and striking of a whole class of similar facts. Such are the results of the contact and mixture of races and languages. If language-history were limited to growth and divarication, and race-history to spread and dispersion, it would be a comparatively easy task to trace both backward toward their origin; as the case is, the confusion is inextricable and hopeless. Mixture of race and mixture of speech are coincident and connected processes; the latter never takes place without something of the former; but the one is not at all a measure of the other, because circumstances may give to the speech of the one element of population a greatly disproportionate
preponderance. Thus, there is left in French only an insignificant trace of the Celtic dialects of the predominant race-constituent of the French people; French is the speech of the Latin conquerors of Gaul, mixed perceptibly with that of the former Frankish conquerors; it was adopted in its entirety by the Norse conquerors of a part of the land, then brought into Britain by the same Norsemen in the course of their further conquests, this time only as an element of mixture, and thence carried with English speech to America, to be the language of a still further mixed community. Almost every possible phase of language-mixture is traceable in the history of the abundant words of Latin origin used by American negroes. What events of this character took place in prehistoric time we shall never be able to tell. If any one chooses to assert the possibility that even the completely isolated dialect of the little Basque community may have been derived by the Iberian race from an intrusive minority as small as that which made the Celts of Gaul speakers of Latin, we should have to admit it as a possibility—yet without detriment to the value of the dialect as indicating the isolated race-position of its speakers. In strictness, language is never a proof of race, either in an individual or in a community; it is only a probable indication of race, in the absence of more authoritative opposing indications; it is one evidence, to be combined with others, in the approach towards a solution of the confessedly insoluble problems of human history. But we must notice, as a most important circumstance, that its degree of probability is greatest where its aid is most needed, in prehistoric periods and among uncultivated races; since it is mainly civilization that gives to language a propagative force disproportionate to the number of its speakers. On the whole, the contributions of language to ethnology are practically far greater in amount and more distinct than those derived from any other source.

The genetical classification of languages, then, is to be taken for just what it attempts to be, and no more; primarily as a classification of languages only; but secondarily as casting light, in varying manner and degree, on movements of community, which in their turn depend more or less upon movements of races. It is what the fates of men have left to represent the tongues of men—a record imperfect even to fragmentariness. Many a family once as important as some of those here set down has perhaps been wiped out of existence, or is left only in an inconspicuous fragment; one and another has perhaps been extended far beyond the limits of the race that shaped it—which, we can never tell to our satisfaction.

1. Indo-European (Indo-Germanic) Family.—To this family belongs incontestably the first place, and for many reasons: the historical position of the peoples speaking its dialects, who have now long been the leaders in the world's history; the abundance and variety and merit of its literatures, ancient and modern, which, especially in the modern, are wholly unapproached by those of any other division of mankind; the period covered by its records; and, most of all, the great variety and richness of its development. These advantages make of it an illustration of the history of human speech with which no other family can bear a man's comparison as to value, however important various other families may be in their bearing on one and another point or department of history, and however necessary the combination of the testimony of all to a solution of the problems involved in speech. These advantages have made Indo-European language the training-ground of comparative philology, and its study will always remain the logical basis of that science. Many matters of importance in its historical development have been brought up and used as illustrations in the preceding discussion; but as its constitution and ascertained development call for a fuller and more systematic exposition than they have found here, a special section is devoted to the subject (see Part II. below; also Indo-European Language).

2. Semitic Family.—This family also is beyond all question the second in importance, on account of the part which its peoples (Hebrews, Phoenicians, Assyrians, Syrians, Arabs, Abyssinians, &c.) have played in history, and of the rank of its literatures. For a special treatment of it see Semitic Languages. Some of the peculiarities of these languages have already been alluded to above; in the monotonous and rigidity of its triliteral roots, and in the extended use which it makes of internal vowel-change ("inflection" in the special sense of that term) for the purpose of grammatical distinction, it is more peculiar and unlike all the other known families of language than these are unlike one another. There are, and perhaps will always be, those to whom the peculiarities just mentioned will seem original; but if the views of language and its history taken above are in the main true, then that opinion is untenable; Semitic language must have grown into its present forms out of beginnings accordant in kind, if not identical in substance, with those of other families; and the only question remaining to be solved is, through what processes and under what governing tendencies Semitic speech should have arrived at its present state. And with this solution is most obviously and incontestably bound up that of the other interesting and much discussed question, whether the Semitic family can be shown to be related with other families, especially with the Indo-European. To some the possession in common of grammatical gender, or of the classification of objects in general as masculine and feminine, is of itself enough to prove such relationship; but, though the fact is a striking one, and of no small importance as an indication, this degree of value can by no means be attributed to it in the present state of our knowledge—any more than to any other single item of structure among the infinite variety of such, distributed among the multitude of human tongues. Many others compare the Semitic and Indo-European "roots" with one another, and believe themselves to find there numerous indications of identity of material and signification; but these also must pass for insufficient, until it shall prove possible by their aid to work out an acceptable theory of how Semitic structure should have grown out of such radical elements as underlie Indo-European structure, or out of the accordant initial products of a structural growth that afterwards diverged into two so discordant forms. To show that, both the material and the method have been hitherto wanting, and any confident decision is at least premature; but present probabilities are strongly against the solubility of the question. While many general considerations favour the ultimate unity of these two great civilized and civilizing white races of neighbouring homes, and no discordance of speech (as was shown above) can ever be made to prove their diversity of origin, it seems in a high degree unlikely that the evidence of speech will ever be made to prove them one.

3. Hamitic Family.—The prominent importance of this family (see Hamitic Languages) is due to a single one of its members, the Egyptian. It occupies the north-eastern corner of Africa, with the border-lands of that continent stretching westward along the whole shore of the Mediterranean, and southward to beyond the equator. It falls into three principal divisions: (1) the ancient Egyptian, with its descendant, the more modern Coptic (itself now for some centuries extinct; see Egypt, Copts); (2) the Libyan or Berber languages of northern Africa; (3) the Ethiopic languages of eastern Africa. Its situation thus plainly suggests the theory of its intrusion from Asia, across the isthmus of Suez, and its gradual spread from that point; and the theory is strongly favoured by the physical character of the Hamites, and the historical position, especially of the Egyptians, so strikingly different from that of the African races in general. Linguistic evidences of the antiquity of Semitic speech in the land of Ham, and by many believed to be found; and by the maintenance of the two families in their separateness is an indication that those evidences have not yet been accepted as satisfactory; and such is indeed the case. The Egyptian is a language of extreme simplicity of structure, almost of no structure at all. Its radical words are partly monosyllabic, partly of more than one syllable, but not in the latter case any more than in the former showing traceable signs of extension by formative processes from simpler
elements. It has no derivative apparatus by which noun-stems are made from roots; the root is the stem likewise; there is nothing that can be properly called either declension or conjugation; and the same pronominal particles or suffixes have now a subjective value, indicating use as a verb, and now a possessive, indicating use as a noun. There is no method known to linguistic science by which the relationship of such a tongue as this with the highly and peculiarly inflective Semitic can be shown, short of a thorough working out of the history of development of each family taken by itself, and a retracing in some measure of the steps by which each should have arrived at its present position from a common starting-point; and this has by no means been done. In short, the problem of the relation of Semitic with Hamitic, not less than with Indo-European, depends upon that of Semitic growth, and the two must be solved together. There are striking correspondences between the pronouns of the two families, such as, if supported by evidences from other parts of their material, would be taken as signs of relationship; but, in the absence of such support, they are not to be relied upon, not till it can be shown to be possible that two languages could grow to be so different in all other respects as are Egyptian and Hebrew, and yet retain by inheritance corresponding pronouns. And the possession of grammatical gender by Indo-European, Semitic and Hamitic speech, and by them almost alone, among all human languages, though an extremely noteworthy fact, is (as was pointed out above) in the present condition of linguistic science quite too weak a basis for a belief in the original identity of the three families.

Egyptian is limited to the delta and valley of the Nile, and is the only Hamitic language which has ancient records; of the others the existing forms alone are known.

The Libyan or Berber division of the family occupies the inhabitable part of northern Africa, so far as it has not been displaced by intrusive tongues of other connexion—in later times the Arabic, which since the Mahomedan conquest has been the cultivated tongue of the Mediterranean coast, while the earlier Vandal, Latin and Punic have disappeared, except in the traces they may have left in Berber dialectic speech. The principal dialects are the Kabyle, the Shilha and the Tuarék or Tamashek, corresponding nearly to the ancient Numidian, Mauretanian and Gaetulian respectively.

The third or Ethiopic division includes as its chief members the Beja or Bishárín, the Sahó, the Dánkali, the Somali, and the more inland Gallà; the first two lying along the Red Sea north of Semitic Abyssinia, the others south of it, to the equator. By some authorities (Leplús, Bleek) there is added to the Hamitic family by the South Arabian, which is limited to the extreme southern Africa, the Hottentot and Bushman languages. The ground of this classification is the possession by the Hottentot of the distinction of grammatical gender, and even its designation by signs closely corresponding to those used in the Ethiopic division. Others deny the sufficiency of this evidence, and rank the Hottentot as a separate group of African dialects, adding to it provisionally the Bushman, until better knowledge of the latter shall show whether it is or is not a group by itself. If the Hottentot be Hamitic, we shall have to suppose it cut off at a very remote period from the rest of the family, and forced gradually southward, while all the time suffering mixture both of speech and of blood with the negro races, until the physical constitution of its speakers has become completely metamorphosed, and of its original speech no signs are left save those referred to above; and while such exceptional phonetic peculiarities have been worked out as the use of the clicks or clucking sounds: and this must be regarded as at least extremely difficult.

4. Monosyllabic or South-eastern Asiatic Family.—This body of languages may well enough be the next taken up; and here again (as was the case with the preceding family) on account of the prominent importance of one of its dialects and of the people speaking it—the Chinese people and language. The territory of the family includes the whole south-eastern corner of Asia: China on the north-east, Farther India in the south, and the high plateau of Tibet, with the neighbouring Himalayan regions, to the westward. The ultimate unity of all these languages rests chiefly upon the evidence of their form, as being all alike essentially monosyllabic and isolating, or destitute of formal structure; the material correspondences among them, of accordant words, are not sufficient to prove them related. The Chinese itself can be followed up, in contemporary records, to a period probably not far from 2000 B.C., and the language, the people, and their institutions, are then already in the main what they have ever since continued to be (see China); the other leading tongues come into view much later, as they receive their present identity from China on the one hand (the Annamites), or from India on the other (the Tibetans, Burmese, Siamese); and the territory includes great numbers of wild tribes unknown until our own times, whose race-relations and language-relations are as yet very obscure. Current opinion tends to regard the Annamites, Peguans and Cambodians (the Mon-Khmer group) as forming a more nearly related group or division, and as having been the earlier population of Farther India, in part dispossessed and driven forward by the later intrusion from the north of Siamese and Burmese, of whom the former are more nearly related to the Chinese and the latter to the Tibetans. The Mon-Khmer group is itself more nearly related to the Koldan and Malay-Polynesian.

The character of the languages of this family, especially as instanced by its most important member, the Chinese, has been pretty fully set forth in the general discussions above. They are languages of roots: that is to say, there is not demonstrable in any of their words a formative part, limiting the word, along with others similarly characterized, to a certain office or set of offices in the formation of the sentence. That the words are ultimate roots, come down from the first period of language-making, we have no reason whatever to believe; and they may possibly have passed through processes of growth which equipped them with some scanty supply of forms; but no evidence to that effect has yet been produced. The indications relied on to show an earlier polysyllabism in the family (though already in Chinese reduced to monosyllabism before the earliest historical appearance of the language, some 4000 years ago) are the comparatively recent loss of certain final mutes in Chinese words, and the presence on a considerable scale in Tibetan spelling of added initial and final consonants, now silent in the literary dialect, but claimed to be still uttered in some parts of the country. If the theory connecting these phenomena be established, the Tibetan will approve itself to be by far the most primitive of the dialects of the family, in contact with the Chinese. The Tibetan dialect is best adapted for study.

For further details respecting the various tongues of the monosyllabic family, the articles on the different divisions of its territory (Burmá; China; Siam; Tibet, &c.) may be consulted. The languages all alike show an addition to the resources of distinction possessed by languages in general, in the use of tones: that is to say, words of which the alphabetic elements are the same differ in meaning according as they are uttered in a higher or a lower tone, with the rising or the falling inflexion, and so on. By this means, for example, the monosyllabic elements of the literary Chinese, numbering but 500 as we should write them, are raised to the number of about 1500 words.

5. Ural-Altaic (Scythian, Turanian) Family.—China and Tibet are bordered on the north and west by the eastern branches of another immense family, which stretches through central and northern Asia into Europe, overlapping the European border in Turkey, and reaching across it in Russia and Scandinavia to the very shore of the Atlantic. Usage has not so definitely determined as in the case of most other families by what name it shall be called; Turanian is perhaps the commonest appellation, but also the most objectionable. Five principal branches are generally reckoned as composing the family. The two easternmost are the Tungusian, with the Manchus for its principal division, and the Mongol (see Mongols).
PHILOLOGY

Of these two the language is exceedingly simple in structure, being raised but little above the formlessness of the Chinese. The Tungusian, however, some authorities would couple with Japanese as a separate branch. The three others are: the Turkish or Tatar, the dialects of which reach from the mouth of the Lena (Yakut) to Turkey in Europe; the Samoyed, from the Altai down to the arctic shore of Asia, and along this to the White Sea—an important congeries of barbarous tribes; and the Finno-Hungarian, including the tongues of the two cultivated peoples from which it takes its name, and also those of a great part of the population of northern and central Russia, to beyond the Ural Mountains, and finally the Lappish, of northern Scandanavia. The nearer relation of the Samoyed is with the Finno-Hungarian. The Turkish is a type of a well-developed language of purely agglutinative structure: that is, lacking that higher degree of integration which issues in internal change. Whether this degree is wholly wanting in Finnish and Hungar is made a question; at any rate, the languages named have no reason to envy the tongues technically called "inflective." Of a value not inferior to that of inflective characteristics is one that belongs to all the Ural-Altaic tongues, in varying measure and form, and helps to bind them together into a single family—the harmonic sequence of vowels, namely, as between root and endings, or a modification of the vowels of the endings to agree with that of the root or its final syllable.

While the physical race-characteristics known as Mongolian are wanting in the speakers of the western dialects of this family, they are conspicuously present in the people of Japan and Korea; and hence the tendency of scholars to endeavour to connect the languages of the two latter countries, since they also are of agglutinative structure (see Japan and Korea) with the family now under treatment, as also with one another.

Other languages of north-eastern Asia, too little known to group, and too unimportant to treat as separate families, may be mentioned here by way of appendix to their neighbours of the most diversified and widespread Asiatic family. They are the Aino, of Yezo and the Kurile Islands with part of the neighbouring coast; the Kamchatkan; and the Yukagir and Tchukchi of the extreme north-east. These are sometimes combined with the Eskimo under the title of the Arctic or Hyperborean languages.

The opinion has been held by many scholars that the agglutinative dialects—Sumerian, Accadian, &c.—of the presumed founders of Mesopotamian culture and teachers of the Assyrian Semites (see BABYLONIA) belonged to the Ural-Altaic family, and specifically to its Finno-Ugrian branch; but the data for this view are still very uncertain. The mere possession of an agglutinative structure cannot be taken as proving anything in the way of relationship.

5. Dravidian or South Indian Family.—This is an important body of nearly and clearly related tongues, spoken by about 50,000,000 people, doubtless representing the main population of all India at the time when the intrusive Indo-European tribes broke in from the north-west, and still filling most of the southern peninsula, the Deccan, together with part of Ceylon. They are languages of a high grade of structure, and of great power and euphony; and the principal ones have enjoyed a long cultivation, founded on that of the Sanskrit. As they obviously have no Indo-European affinities, the attempt has been made to connect them also with the Ural-Altaic or Turanian family, but altogether without success, although there is nothing in their style of structure that should make such connexion impossible.

6. Malay-Polynesian Family. Not all the tribes that make up the Malay-Polynesian family are of an equal population. The Dinka dialects. The Santals and certain other wild tribes appear to be of another lineage. These are now generally known as Kolarian, and are connected with the Malay-Polynesian family.

The islands, greater and smaller, lying off the south-eastern coast of Asia and those scattered over the Pacific, all the way from Madagascar to Easter Island, are filled with their own peculiar families of languages, standing in a more or less distant relationship to the languages of the Mon-Khmer group, and the Kolarsians on the mainland and the Nioborians. The principal one among them is the great Malay-Polynesian family. It falls into two principal divisions, Malay and Polynesian. The Malayan includes, besides the Malay proper (see MALAYS), which occupies the Malaccan peninsula (yet doubtless not as original home of the division, but by immigration from the islands), the languages also of Sumatra, Java, Borneo, &c., of the Philippine Islands, of part of Formosa, and of Madagascar, together with the coasts of Cebes and other islands occupied in the interior by Papuans. The Polynesian division includes most of the tongues of the remaining scattered groups of islands, and that of New Zealand. Probably to these are to be added, as a third division, the Melanesian dialects of the Melanesian Archipelago, of which both the physical and the linguistic peculiarities would in that case be ascribed to mixture with the black Papuan races. All these languages are extremely simple in phonetic form, and of a low grade of structure, the Polynesian branch being in both respects the lowest, and some of the Malayan dialects having reached a development considerably more advanced. The radical elements are much oftener of two syllables than of one, and reduplication plays an important part in their extension and variation. Malay literature goes back as far as to the 15th century, and there are Javan records even from the early centuries of our era, the result of religion and culture introduced into that island from Brahmanic India. In recent years more active investigation has been carried on with a view to tracing out the special laws of historical development prevailing in the family.

8. Other Oceanic Families.—At least two other families, unconnected with the preceding and with one another, are found among the Pacific Islands, and only there. The continental island of Australia, with its dependency Tasmania (where, however, the native tongue has now become extinct), has its own body of probably related dialects, as its own physical type. They have been but imperfectly investigated, their importance, except to the professed student of language, being nothing; but they are not destitute of a rude agglutinative structure of their own. Still less known are the Papuan or Negrito languages, belonging to the black race with frizzled hair inhabiting most of New Guinea, and found also in the interior of some of the other islands, having been driven from the coasts by superior intruders of the Malay race.

9. Caucasian Languages.—Of the existing languages of Asia there remain to be mentioned only those of the Caucasian mountains and highlands, between the Black and Caspian Seas, pressed upon the north by Slavonians and Turks, upon the south by Armenians and Kurds and Turks. Its situation makes the Caucasus a natural eddy in all movements of emigration between Asia and Europe; and its linguistic condition is as if remnants of many families otherwise extinct had been stranded and preserved there. The dialects north of the principal range—Circassian, Mtsjheghian, Leshchian, &c.—have not been proved to be connected either to one another or to those of the south. Among the latter, the Georgian is much the most widespread and important (see Georgia) and, alone among them all, possesses a literature. The Caucasian dialects present many exceptional and difficult features, and are in great part of so high a grade of structure as to have been allowed the epithet inflective by those who attach special importance to the distinction thus expressed.

10. Remnants of Families in Europe.—The Basque people of the western Pyrenees, at the angle of the Bay of Biscay, are shown by their speech to be an isolated remnant of some race which was doubtless the oldest in this northern part of Europe. It has nowhere elsewhere lost its separate identity; as such it is of extreme interest to the ethnologist (see BASQUE). The Basque language appears to be unrelated to any other on earth. It is of a very highly agglutinative structure, being equalled in intricacy of combination only by a part of the American dialects. Limited as it is in territory, it falls into a number of well-marked dialects, so that it also may not be refused the name of a "family."

The only other case of the kind worth noting is that of the
the less the America the 1897, likely by to Language sex, the no closely far Indo-European, But polysynthetism, the belongs small F. the more of southern and a hundreds, most varying hundreds, which the various classes or genders (not founded on sex; the ground of classification is generally obscure) of nouns are distinguished; these then reappear in the other members of the sentence, as adjectives and verbs and pronouns, which are determined by the noun, thus producing an alliterative concord that runs through the sentence. The phonological determinants of the verb, both subject and object, also come before it; but the determinants of mode of action, as causative, &c., are mostly suffixed. The language in general is rich in the means of formal distinction. Those dialects which border on the Hottentot have, apparently by derivation from the latter, the clicks or clucking-sounds which form a conspicuous part of the Hottentot spoken alphabet. The Bantu group, extending from north of the equator to the Cape of Good Hope, with a vast variety of dialects, is the most important of all African languages. To it belongs Swahili, the language of Zanzibar, only less valuable as a means of communication and trade than the Hausa of the Sudan, the most important of the dialects under the influence of the Hamitic languages. The African languages are by no means to be called a family, but rather a great mass of dialects, numbering by hundreds, of varying structure, as to the relations of which there is great discordance of opinion even among the most recent and competent authorities. It is no place here to enter into the vexed questions of African linguistics, or even to report the varying views upon the subject; that would require a space wholly disproportionate to the importance of African speech in the general sum of human language. There is no small variety of physical type as well as of speech in the central belt; and, partly upon the evidence of lighter tint and apparently higher endowment, certain races are set off and made a separate division of; such is the Nubia-Fulah division of F. Müller, rejected by the latter regarded all the varieties of physical and linguistic character in the central belt as due to mixture between pure Africans of the south and Hamites of the north and east; but this is at present an hypothesis only, and a very improbable one, since it implies modes and results of mixture to which no analogies arequotable from languages whose history is known; nor does it appear at all probable that the collision of two races and types of speech should produce such an immense and diverse body of transitional types. It is far from impossible that the present prominence of the South African or Bantu family may be secondary, due to the great expansion under favoring circumstances of a race once having no more importance than belongs now to many of the Central African races, and speaking a tongue which differed from theirs only as theirs differed from one another. None of the Central African languages is a prefix-language in the same degree as the Bantu, and in many of them prefixes play no greater part than in the world's languages in general; others show special forms or traces of the prefix structure; and some have features of an extraordinary character, hardly to be paralleled elsewhere. One group in the east (Oigob, &c.) has a gender distinction, involving that of sex, but really founded on relative power and dignity: things disparaged, including women, are put in one class; things extolled, including men, are put in the other. This is perhaps the most significant hint anywhere to be found of gender-distinction, like that in our own Indo-European languages, which we usually regard as being essentially a distinction of sex, while in fact it only includes such, may have arisen. Common among the African languages, as among many other families, especially the American, is a generic distinction between animate beings and inanimate things.

12. Central African Languages. — The remaining languages of Africa form a broad band across the centre of the continent, between the Bantu on the south and the Hamitic on the east and north. The Bantu group, extending from north of the equator to the Cape of Good Hope, with a vast variety of dialects, is the most important of all African languages. To it belongs Swahili, the language of Zanzibar, only less valuable as a means of communication and trade than the Hausa of the Sudan, the most important of the dialects under the influence of the Hamitic languages. The African languages are by no means to be called a family, but rather a great mass of dialects, numbering by hundreds, of varying structure, as to the relations of which there is great discordance of opinion even among the most recent and competent authorities. It is no place here to enter into the vexed questions of African linguistics, or even to report the varying views upon the subject; that would require a space wholly disproportionate to the importance of African speech in the general sum of human language. There is no small variety of physical type as well as of speech in the central belt; and, partly upon the evidence of lighter tint and apparently higher endowment, certain races are set off and made a separate division of; such is the Nubia-Fulah division of F. Müller, rejected by the latter regarded all the varieties of physical and linguistic character in the central belt as due to mixture between pure Africans of the south and Hamites of the north and east; but this is at present an hypothesis only, and a very improbable one, since it implies modes and results of mixture to which no analogies are quotable from languages whose history is known; nor does it appear at all probable that the collision of two races and types of speech should produce such an immense and diverse body of transitional types. It is far from impossible that the present prominence of the South African or Bantu family may be secondary, due to the great expansion under favoring circumstances of a race once having no more importance than belongs now to many of the Central African races, and speaking a tongue which differed from theirs only as theirs differed from one another. None of the Central African languages is a prefix-language in the same degree as the Bantu, and in many of them prefixes play no greater part than in the world's languages in general; others show special forms or traces of the prefix structure; and some have features of an extraordinary character, hardly to be paralleled elsewhere. One group in the east (Oigob, &c.) has a gender distinction, involving that of sex, but really founded on relative power and dignity: things disparaged, including women, are put in one class; things extolled, including men, are put in the other. This is perhaps the most significant hint anywhere to be found of gender-distinction, like that in our own Indo-European languages, which we usually regard as being essentially a distinction of sex, while in fact it only includes such, may have arisen. Common among the African languages, as among many other families, especially the American, is a generic distinction between animate beings and inanimate things.

13. American Languages. — With these the case is closely the same as with the Central African languages: there is an immense number of dialects, of greatly varied structure (see Indians, North American). Even among neighbouring families like the Algonquin, Iroquois and Dakota, whose agreement is most conspicuous, the construction of words, the agreement with the accordant race-type of their speakers, forbids us to regard them as ultimately different, no material correspondence, agreement in words and meanings, is to be traced; and there are in America all the degrees of polysynthesis, down to the lowest, and even to its entire absence. Such being the case, it ought to be evident to every one accustomed to deal with this class of subjects that all attempts to connect American languages as a body with languages of the Old World are and must be fruitless.

Literature. — Many of the theoretic points discussed above are treated by the writer with more fulness in his Language and the Study of Language (1867) and Life and Growth of Language (1875). Other English works to consult are M. Müller's Lectures on the Science of Language; Farrar's Chapters on Language; Wedgwood's Origin of Language (all more or less antiquated); Sayce's Principles of Philology and Introduction to the Science of Language, &c.; Sweet, The History of Language (1900). In German, see Paul's Principien der Sprachgeschichte (Halle, 1880); Delbrück's Einleitung in das Sprachstudium (Leipzig, 1880; 4th ed., 1905; 5th ed., 1910; there is also an English version); Brugmann and Delbrück's Grundriss der vergleichenden Grammatik der indoarischen Sprachen (1876-1900; a second edition of the first volume was published in 1897, two parts of vol. i., including the stem-formation and declension of the noun and pronoun appeared in 1906 and 1909); also the works of W. von Humboldt and of H. Steinthal, the most important of whose linguistic works, Charakteristik der hauptsächlichsten Typen des Sprachbaues (1861), was recast and brought up to date under the same title by F. Mistel (1860). See also handy summaries covering the same ground, but without bibliography, in F. N. Finck's Die Sprachstämme des Erdbreises (1900) and Die Haupttypen des Sprachbaus (1910). Many of the languages of India and Farther India have been treated in the Linguistic Survey of India, edited by Dr. G. E. Cowper (a government publication still in progress). A short popular account of the subject is given in Porzczinski's Einleitung in die Sprachwissenschaft (1910), a German translation of a Russian original. The Bantu languages have been treated by Black, Torranda, and most recently by Meinhof, whose Laulohre der Bantu Sprachen (1910) is the most complete handling of the subject. As to the classification and relationships of languages, see Hovelacque's La Linguistique (Paris, 1876) and F. Müller's Grundriss der Sprachwissenschaft (Vienna, 3 vols.; a fourth was left incomplete at the author's
Bopp's researches, and thus fixing his attention on a group of idioms exhibiting a striking regularity in their mutual relationship, both where they coincide and where they differ, he made it his foremost object to investigate and illustrate the continuous progress, subject to definite laws, by which these languages had been developed from their common source. He thus raised the hitherto neglected study of the development of sounds to an equal level with the study of grammatical forms, which had so far almost exclusively absorbed all the interest of linguistic research.

Grimm's discovery of the so-called "Lautverschiebungen," or Law of the Permutation of Consonants in the Teutonic languages (which, however, had been partly found and proclaimed before Grimm by the Danish scholar Rask), became especially important as a stimulus for further investigation in this line. Grimm's influence on comparative philology (which is secondary only to that of Bopp, although he was never a comparative philologist in the sense that Bopp was, and did not always derive the benefit from Bopp's works which they might have afforded him) is clearly traceable in the work of Bopp's successors, among whom Friedrich August Pott (1826-1858) is universally judged to hold the foremost rank. In his great work, *Eymologische Forschungen auf dem Gebiete der indogermanischen Sprachen, mit besonderem Bezug auf die Lautumwandlung im Sanskrit, Griechischen, Lateinischen, Littauischen, und Gothischen* (Lemgo, 1833-1836), we find Indo-Scandinavian etymology for the first time based on a scientific investigation of general Indo-European phonology. Amongst Pott's contemporaries Theodor Benfey deserves mention on account of his *Griechisches Wurdewerks* (Berlin, 1839), a work equally remarkable for copiousness of contents and power of combination, yet showing no advance on Bopp's standpoint in its conception of phonetic changes.

A third period in the history of Indo-European philology is marked by the name of August Schleicher, whose *Compendium der vergleichenden Grammatik der indogermanischen Sprachen* first appeared in 1861. In this period subsequent to the appearance of Pott's *Eymologische Forschungen*, a number of distinguished scholars, too large to be recorded here individually, had devoted their labours to the different branches of Indo-European philology, especially assisted and promoted in their work by the rapidly progressing *Vedische* and *Avestische* studies that had been inaugurated by Rosen, Roeder and Westergaard. Moreover, new foundations had been laid for the study of the Slavonic languages by Miklosich and Schleicher, of Lithuanian by Kurschat and Schleicher, of Celtic by Zeus. Of the classical languages Greek had found a most distinguished representative in Curtius, while Corssen, Mommsen, Aufrecht, Kirchhoff, &c., had collected most valuable materials towards

Bopp and J. Grimm.

Bopp's researches, and thus fixing his attention on a group of idioms exhibiting a striking regularity in their mutual relationship, both where they coincide and where they differ, he made it his foremost object to investigate and illustrate the continuous progress, subject to definite laws, by which these languages had been developed from their common source. He thus raised the hitherto neglected study of the development of sounds to an equal level with the study of grammatical forms, which had so far almost exclusively absorbed all the interest of linguistic research.

Grimm's discovery of the so-called "Lautverschiebungen," or Law of the Permutation of Consonants in the Teutonic languages (which, however, had been partly found and proclaimed before Grimm by the Danish scholar Rask), became especially important as a stimulus for further investigation in this line. Grimm's influence on comparative philology (which is secondary only to that of Bopp, although he was never a comparative philologist in the sense that Bopp was, and did not always derive the benefit from Bopp's works which they might have afforded him) is clearly traceable in the work of Bopp's successors, among whom Friedrich August Pott (1826-1858) is universally judged to hold the foremost rank. In his great work, *Eymologische Forschungen auf dem Gebiete der indogermanischen Sprachen, mit besonderem Bezug auf die Lautumwandlung im Sanskrit, Griechischen, Lateinischen, Littauischen, und Gothischen* (Lemgo, 1833-1836), we find Indo-Scandinavian etymology for the first time based on a scientific investigation of general Indo-European phonology. Amongst Pott's contemporaries Theodor Benfey deserves mention on account of his *Griechisches Wurdewerks* (Berlin, 1839), a work equally remarkable for copiousness of contents and power of combination, yet showing no advance on Bopp's standpoint in its conception of phonetic changes.

A third period in the history of Indo-European philology is marked by the name of August Schleicher, whose *Compendium der vergleichenden Grammatik der indogermanischen Sprachen* first appeared in 1861. In this period subsequent to the appearance of Pott's *Eymologische Forschungen*, a number of distinguished scholars, too large to be recorded here individually, had devoted their labours to the different branches of Indo-European philology, especially assisted and promoted in their work by the rapidly progressing *Vedische* and *Avestische* studies that had been inaugurated by Rosen, Roeder and Westergaard. Moreover, new foundations had been laid for the study of the Slavonic languages by Miklosich and Schleicher, of Lithuanian by Kurschat and Schleicher, of Celtic by Zeus. Of the classical languages Greek had found a most distinguished representative in Curtius, while Corssen, Mommsen, Aufrecht, Kirchhoff, &c., had collected most valuable materials towards
the elucidation of Latin and the cognate Italic idioms. In his Compendium Schleicher undertook and solved the difficult task of sifting down the countless details amassed since the days of Bopp and Grimm, and thus making the individual languages stand out clearly on their common background, while Bopp's attention had been especially occupied with what was common to all Indo-European tongues. There are two prominent features which characterize this part of Schleicher's work—his assumption and partial reconstruction of a pre-historic parent speech, from which the separate Indo-European languages were supposed to have sprung, and the establishment of a long series of phonetic laws, regulating the changes by which that development of the individual idioms had taken place. On Schleicher's views of and contributions to the active part of the science which he erroneously proposed to consider as a branch of natural science we need not enter here. (See Evolution and the Science of Language in Darwin and Modern Science, 1909, pp. 236 sqq.)

For some time after Schleicher's premature death (in 1868) Indo-European philology continued in paths indicated by him and Curtius, with the exception, perhaps, of the school founded by Benfey, who had always stood on independent ground. The difference between the two schools, however, was less strikingly marked in their writings, because it chiefly concerns general views of language and the Indo-European languages in particular, although the characteristic task of the period alluded to was that of working out the more minute details of comparison; but behind all this the general interest still clung to Bopp's old glotto-gonic problems. In 1876, however, a new movement, inspired in the first instance by the works of W. D. Whitney, began, and a younger school of linguists has sprung up who are united in their opposition to many theories of the older generation, yet often differ materially both with regard to method and the solution of individual problems. In its present state this younger school (often branded with the name of Neo-Grammarians, Junggrammatiker, by its opponents real and imaginary) is marked by certain distinct tendencies. In the first place, they are inclined more or less, and the older members of the school perhaps more than the younger, to abandon glotto-gonic problems as insoluble, if not for ever, yet for the present and with the scanty means that Indo-European philology alone can furnish for this inquiry. In this they are in opposition to the whole of the older school. In the second place, they object to the use of all misleading metaphorical comparisons of processes in the history of language with processes of organic development—comparisons used at all times, but especially cherished by Schleicher. In the third place—and this has been of the greatest practical importance—that our general views of language and our methods of comparison should be formed after a careful study of the living languages, because these alone are fully controllable in every minute detail, and can therefore alone give us a clear insight into the working of the different motive forces which shape and modify language, and that the history of earlier periods of language, consequently, can only be duly illustrated by tracing out the share which each of these forces has had in every individual case of change. Of these forces two are found to be especially prominent—phonetic variation and formation by analogy. They generally work in turns and often in opposition to one another, the former frequently tending to differentiation of earlier unities, the latter to abolition of earlier differences, especially to restoration of conformity disturbed by phonetic change. There are, however, other important differences in the action of the two forces. Phonetic change affects exclusively the pronunciation of a language by substituting one sound or sound-group for another. From this simple fact it is self-evident that phonetic changes as such admit of no exceptions. Pronunciation—that is, the use of certain sounds in certain combinations—is perfectly unconscious in natural unstudied speech, and every speaker or generation of speakers has only one way of utterance for individual sounds or their combinations. If, therefore, a given sound was once changed into another under given circumstances, the new sound must necessarily and unconsciously replace its predecessor in every word that falls under the same rules, because the older sound ceases to be practised and therefore disappears from the language. Thus, for instance, the sound of the short so-called Italian a in English has become exchanged for the peculiarly English sound in man, hat, &c., which is so exclusively used and practised now by English speakers that they feel great difficulty in pronouncing the Italian sound, which at an earlier period was almost as frequent in English as in any other language that has preserved the Italian sound up to the present day. Again, the sound of the so-called long English a in make, paper, &c., although once a monophthong, is now pronounced as a diphthong, combining the sounds of the English short e and i, and no trace of the old monophthong is left, except where it was followed by r, as in hare, mare (also air, their, where, &c.), where the a has a broader sound somewhat approaching that of the short a in hat. This last instance may at the same time serve to illustrate the restrictions made above as to sounds changing their pronunciation in certain groups or combinations, or under given circumstances only. We may learn from it that phonetic change need not always affect the same original sound in the same way in all its combinations, but that neighboring sounds often influence the special direction in which the sound is modified. The different sounds of the English hare and hare are both equivalents of the same Old English sound ð (=the Italian short a) in macian, hara. The latter sound has been split in two, but this process again has taken place with perfect regularity, the one sound appearing before r, the other before all other consonants. It is easy to see that the common practice of comprising the history of the Old English a in the one rule—that it was changed into the sound of the ð in make except when followed by an r—can only be defended on the practical ground that this rule is convenient to remember, because the words exhibiting the former change are more numerous than the instances of the latter; apart from this there is nothing to justify the assumption that one of these changes is the rule and the other the exception. The fact is, that we have two independent cases of change, which ought to be stated in two distinct and independent rules according to the different positions in which the original ð stood before the splitting began. It is also easy to observe that the variety of modifying influences may be much more manifold than in the present instance of make and hare, and that the number of special phonetic rules in such cases must be increased in proportion to the progress made in the investigation of the said modifying processes.

In truth, however, the study of phonetic laws falls into several different stages, and the meaning attached to the phrase phonetic law has varied at each of these stages. Moreover, the sweeping nature of the original generalizations has become so hedged in and contracted by limitations that a recent writer has been compelled once more to formulate the question whether phonetic laws actually exist. It must be admitted in the first place that the word law has been ill chosen for use in this connexion. In phonetic laws there is no element which can be identified as coming under the definition of a law as propounded by a jurist like John Austin. There is no authority which enunciates the law, there is no penalty for the breach of it. But the philologists who first used the term were not thinking of law in its strict signification, but of its use in such metaphorical expressions as scientific laws, for, as already mentioned, Schleicher and his followers in the middle of the 19th century had taken a keen interest in the development of the natural sciences, and had to some extent assimilated their terminology to that employed in those sciences. It was, however, soon recognized that the laws of language and those of natural science were not really alike or akin. A scientific "law" is only a brief method of expressing the fact that universal experience shows that certain causes universally produce certain effects. In chemistry two atoms of
hydrogen and one of oxygen will make water, and they will make nothing else at any time or at any place the world over. Phonetic laws, however, do not hold true universally. They are often curiously limited in the area to which they apply. In ancient Greek, for example, the sound -s- between two vowels, which had been handed down from the original language whence Greek and the sister languages are derived, regularly disappears; in Latin, on the other hand, it changes into -t-; thus an original genitive of a neuter substantive probably written without in Greek by 
γενεως, a form which comparison with other languages shows to be traceable to an earlier *genes-ος, preceding the separation of the languages, while the same original stem with a different vowel in the ending appears in Latin as gener-itis. Similarly an early *ευς appears in Greek as έδυ, in Latin as utro. This disappearance of original intervocalic s pervades all Greek dialects—the apparent exceptions come under the heading of analogical change; with a very few exceptions similarly explainable Latin intervocalic s has become r. But Latin was originally limited to a very small part even of Italy, and the next neighbours of the Latins on the east and south—the Sabines, Campanians and Samnitse—retained this intervocalic s without changing it into r. On the other hand, the neighbours to the north-east—the Umbrians in and beyond the Apennines—shared in this rhotacism. Yet the Celts, who bordered on the Umbrians along the Po, and who spoke a language in many respects very closely akin to the dialects of Italy, in this regard agree rather with Greek than the Italic languages. In Latin, again, the period of action of the law which changed intervocalic s into r did not in all probability exceed the century from 450 B.C. to 350 B.C. So unlike, indeed, are phonetic laws to the laws of natural science in universality that an opponent of the dogma which declares that phonetic laws have no exceptions has compared them with the laws of fashion. The comparison is not so outrageous as it may seem at first sight. For in language there are two kinds of sound change, that which is unconscious, universal at a given time and within a given area, and, on the other hand, that which belongs only to a particular class or clique, deviates consciously from the pronunciation of the majority, is therefore not universal, and exercises no permanent influence on the language. The second kind of sound change corresponds exactly to the laws of fashion; it is in fact one of them. Such sound changes are the pronunciation of the English ending *-ing as -eɪ, which was fashionable in the middle of the 19th century. The English tongue, though it had borrowed knowledge of those who used it, an historical justification in the earlier forms from which most of the English words now ending in *-ing are descended, and which survive in numerous local dialects. A similar conventional mispronunciation was the lips affected by some would-be artistic persons at a somewhat later period. Belonging to an entirely different social stratum, and now equally obsolete, was the London pronunciation of the first half of the 19th century typified in Tony and Sam Weller's treatment of s and w in the Pickwick Papers. This, however, made a much nearer approach to being a genuine dialect peculiarity. It unabashedly pervaded the pronunciation of the lower classes in London, and it is not surprising therefore to find that it have spread over a wider and wider area until it embraced the whole population of England. A later change, that of the diphthong ai into ei (so that day, daily are pronounced dy, dilly), has spread from Essex and the East End of London over a large part of London and of the adjacent counties, and is still widening its range both geographically and socially. The history of these sound changes has not yet been investigated in detail with the thoroughness which it deserves.

There is, then, a part of sound change which is a matter of fashion and which is conscious. This sound change appears frequently in the pronunciation of individuals who have migrated from the vicinity to parts of Scotland, for example, the prepositions with and of appearing in the diajalt only in the forms wi and of, which were originally the unaccented forms. In the conscious attempts to pronounce them as they appear in literary English, the educated Scotsman, if he remains in his native place, as a rule pronounces them as with (with the final sound unvoiced as it appears in the Scottish legal preposition ouch) and as, the final sound here also being unvoiced. If he migrates to England or to Australia he will probably in course of time adopt the pronunciation with a voiced final sound. In the course of years habit will become second nature, and in this respect the speaker's pronunciation will be at one and the same time distant from and similar to that of his great-great-grandfather. It is clear, however, that changes of this nature cannot take place on a large scale. If a large number of persons migrated to a body and continued to live in close intercourse with one another and but little in contact with the outside world, changes such as take place in the pronunciation of the individual emigrant do not occur. There can be no imitation of alien sounds, for there are none; no greater effort to be intelligible is required, for the audience has not changed. Hence it has been often remarked that a population which history shows to have remained undisturbed for very long periods in the same geographical situation manifests but little change in its language. Thus in Arabia and Lithuania the population has remained practically unaltered in the same habitat for thousands of years, with the result that the languages spoken there remain at the present day the most archaic members of the linguistic families to which they respectively belong.

From what has been said it will be obvious that a phonetic law is only an observed uniformity in the treatment of a sound or a combination of sounds within a linguistic area at a given time. In the definition the term linguistic area is a very variable quantity. Thus it is a phonetic law that a sound of the original Indo-European language, the precise pronunciation of which cannot be determined, but which was at any rate a palatal sound (l'), appears in the Indo-European group (Sanskrit, Zend, Old Persian, with their descendants), in Armenian, in Balto-Slavonic and Albanian, in the form of a sibilant, while in Greek, the Italic dialects, Germanic and Celtic, it appears as a s-sound (see Indo-European Languages). Here the linguistic area is extremely wide, and it is clear that the difference between the two groups of languages must be dated back to a very early period. Again, it is a phonetic law of Greek that the original combination st- at the beginning of words is retained in Greek. How then are we to explain the existence side by side of σιγος and σιγος? The former apparently complies with the law, the latter does not. The former has by its side the verb σιγε, while σιγος is supported only by the rare σιγη. Yet the forms of the verb and substantive found in the Germanic languages leave no doubt that the forms without s represent the ancient old form, for the English third-sound could not have changed its original t- into th- if it had been preceded by s, the law being as strict for English as for Greek that initial st- remains unchanged. On the other hand, a phonetic law may be limited to a very small area. Thus in the dialect of Etruria, and nowhere else within the area of the Ionic dialect of ancient Greek, do we find the change of the sound which appears elsewhere in Greek as between vowels into -pi: σιγεω for σιγεω (acc. sing.), παραβαλικων for παραβαλικων (3pl. subjunctive). Why this change should take place here and nowhere else do we not know, although it may be conjectured that the cause was a misapplication of the phonetic law which in the Greek languages manifested itself in pronunciation which ancient tradition preserved. Undoubtedly such mixtures are the chief conditions of phonetic change, the effect of which is universal. The manner in which the change takes place is that the basis of articulation, the method in which the sound is produced, becomes changed. Thus along the "Highland line" in Scotland, where the English and Gaelic-speaking populations had their linguistic frontier for centuries, the wh- of English, the Anglo-Saxon hu-, becomes universally f-, who? becoming fa? white, file, etc., f being the sound which it was most easy to substitute for the difficult hu-. The history of Spanish in the different communities of South America excellently illustrates this point. After the discovery of the New World, the Spaniards migrated to Chile, who ultimately, and chiefly by intermarriage, incorporated amongst them a considerable element from amongst the native Araucanian Indians. The result has been
that the language of Chile is Spanish, pronounced not with the genuine sounds of Spanish, but with the sounds of the Araucanian language substituted for them. Elsewhere in Spanish America the language of the conquerors remained comparatively pure, because the Spaniards were much fewer in number, and had therefore to maintain themselves a caste apart. For the same reason Latin has split up into the numerous forms which we know as the Romance languages. The particular line of development which, e.g. French followed as compared with Spanish or with the language of the Rhaetian Alps was conditioned by the nature of the sounds in the language which preceded it in the same area, and which was spoken by the ancient Gauls who adopted Latin. The difficulty found in all of these cases is precisely of the same kind as that which an adult at the present day speaking one language finds in attempting to learn the pronunciation of another language. On the one hand, it is only with the greatest difficulty that muscles for many years accustomed to perform one set of movements can be forced into performing another set, which are very similar but yet not identical; on the other hand, to an untrained ear the difference between the two sounds may remain unappreciated. The result is that the new language is pronounced with the sounds of the speaker's original language. If the new language is adopted by a whole people to whom it was originally foreign, the children naturally learn it from their parents with the sounds of the old language which has now become obsolete. Thus the basis of articulation is changed, and if, as was the case with Latin, this process be frequently repeated among peoples speaking languages with articulation widely differing one from another, it is clear that a series of different dialects of the adopted language has been created. This kind of change is immediate and universal throughout the whole area where linguistic change has taken place.

Analogical change, on the other hand, does not affect the pronunciation of a language as a whole in the way that phonetic change does, but is confined to the formation, inflexion, syntax and meaning of single words or groups of words, and therefore is very apt to bear an entirely arbitrary and irregular character. A few instances will be sufficient to illustrate this and also to show how the apparently irregular phenomena of analogy may be classified. (a) In Old English a certain number of substantives formed their plurals by mutation of the root vowels, as fæt, fæt, or bōc, bōc. In Modern English this system of inflexion has been preserved in some cases, as in foot, feet, and altered in others, as book, books. Now, while foot, feet and book are the regular modern phonetic equivalents of the old fōt, fōt, bōc, the plural books can in no way be phonetically traced back to the old bōc, the phonetical equivalent of which in Modern English would be *beech. The only possible explanation of a form like books is that the older bōc was at some date given up and replaced by an entirely new formation, shaped after the analogy of the numerous words with a plural in -s without modification of the root-vowel. Such changes, which are very numerous, exemplify the first kind of analogy, which is generally termed formal analogy. Other examples are the almost entire disappearance from the language of the forms in er and en, which were earlier used as plurals in English. That they were originally stem and not case suffixes does not affect the point. In Middle English, as in Modern English, oxen was spelt as a plural; oxen survives, but oxen, except in such dialect forms as the Scotch e'en, has been replaced by the form in -s: eyes. Similarly in Middle English the suffix -er existed in many words which had been originally of the neuter gender. Thus the plural of child was children, of calf was calves, traces of which, besides the survival in dialect of childer and of calver (both in the 16th century in northern Scotch pronounced as cahr—which is still in common use), are to be found in the place, and hence personal, names Childer-ley and Calver-ley. The old plural of brother was brethren, where the suffix, however, contained an original -r, not -s changed into -r, as did children and calver. In Old English, alongside the form for child making a plural childer, there had been a masculine form making its plural in -s. It would not have been surprising there-fore if in Modern English the plural of child had been children. But in spite of the common tendency to make the plural of all nouns in -s, child has gone in the opposite direction and has not only maintained its -r, but has added to it the -en of stems like oxen and even. InWelsh we find a similar plural to call, calwen, but here calves has long replaced in the literary language both the other forms.

(b) Let us now take another instance from the English verb. In Old English the different persons of the preterite indicative in the so-called strong (irregular) verbs were generally distinguished by different root-vowels; rīdan, “to ride,” and bīdan, “to bind,” for instance, form their preterites thus; ic rǣd, ðū rǣd, kē rǣd, wē, gē, hē rīdan, and ic bond, ðū bunde, hē bund, wē, gē, hē bunden. In modern English this difference in the root-vowels has been abandoned, and rode, bound now stand for all persons, rode being the modern phonetic equivalent of the 1st and 3rd sing. rād, while bound represents the u- form of binden. When one form or set of forms ousts other varying forms from the same paradigm, the change is described variously as material or logical analogy. In such a change of levelling to that seen in rode has been carried through in all preterites of Modern English, regularity prevails even here, though a few traces of the old conflict are still visible in such poetic forms as sung for the preterite side by side with sang. But when we look to its results in the individual verbs we soon find that the choice amongst the different forms which might have served as starting-points has been entirely arbitrary. It is indeed impossible to say why the old singular form should have been chosen as a model in one case, as in rode, and the old plural form in another, as in bound. From these and numerous similar instances we must draw the conclusion that it is beyond our power to ascertain whence analogical changes start, and to what extent they may be carried through when once begun. All we can do is to classify carefully the single cases that come under our observation, and in this way to investigate where such changes are especially apt to take place and what is their general direction. As to the latter points, it has been observed before that levelling of existing differences is one of the chief features in analogical change (as in the case of rode and bound). As to the former, it must be borne in mind that, before any analogical change can take place, some mental connexion must exist between the words or forms serving as models and those which are remodelled after the types suggested to the minds of the speakers through the former. Of such natural mental combinations two classes deserve special notice: the mutual relationship in which the different, say inflexional, forms of the same word stand to each other, and the more abstract analogies between the inflexional system of word-groups bearing a similar character, as, for instance, the different declensions of nouns and pronouns, or the different conjugations of verbs. The instance of rode, bound may serve to illustrate the former category, that of books the latter. In the first case a levelling has taken place between the different forms of the root-vowels once exhibited in the different preterite forms of rīdat or bīdan, which clearly constitute a natural group or mental unity in consequence of their meaning. The form of rode as a plural has simply been taken from the old singular rād, the long a of which has become in Modern English ə, that of bound as a singular from the old plural bundon, the u- sound of which has in Modern English come to be pronounced as a diphthong. In the case of book, books for bōc, bōc, this explanation would fall short. Although we might say that the vowel of the singular here was carried into the plural, yet this would not explain the plural -s. So it becomes evident that the old declension of bōc, bōc was remodelled after the declension of words like arm, arms, where the vowel of the singular was -s. The changes indicated may generally be shown by a proportion, the new analogical formation being the unknown quantity to be ascertained. Thus in the case cited above, arm: arms = book: x; and clearly the form to be ascertained is books. Isolated words or forms which are no part of natural groups or systems, inflexional, formative or syntactical must be regarded as commonly safe from alterations
through analogy, and are therefore of especial value with regard to establishing rules of purely phonetic development.

(c) In syntactical analogy the mental connection between the two series of constructions between which the change takes place is generally still more conspicuous. The connexion may be one of similar or of contrasted meaning. In Latin, adjectives of fullness, like other adjectives, do not originally were followed by the genitive case; participles, on the other hand, were followed by the instrumental ablative. Thus Plautus in the Aulularia 813 and elsewhere could say aulam auris plenam, "a pot full of gold," or soz aulam onustam auro, "a pot laden with gold." From these the transition was easy to the construction aulam onustam auri, as if in English one should say (as was possible in Earlier English), "a pot laden of gold." In English, contrasted words often tend to assimilate their syntactical constructions. Thus, the adjectives like and similar are followed by the preposition to (though in Modern English like need have no preposition), and upon the analogy of such words, different and diverse, with which correct speakers and writers couple from, are by no means rarely followed by to. Nor is it uncommon to hear or to see differ with instead of differ from, upon the analogy of agree with. Curiously enough, Latin, from which differ is descended, is found to follow the same analogy even in good writers. Thus Cicero (Academia Pr. ii. 143) combines dissidere with cum, as later does Seneca (Epistulae, 18. 1).

(d) In the development of analogy in meaning, similarity of sound is often the most effective cause. Thus imperfect is properly irrelevant, not to the point, and is still so used in legal language; its more common signification of "saucy" arises from its accidental resemblance in sound to pert, a word which curiously enough has reversed its meaning, being now used in the sense of mal-apert, while the Old French apert, asperton (a confusion of Lat. apartus, "open," with expertus, "skilled"), meant both "open" and "skillful." Thus from very early times the verbs fly and flee have been confused, though they are of entirely different origins. When Middle English began to lose its verb endings in -en, it was very easy for the verb leren, "teach," and lernen, "learn," to be confused. Hence frequently in Elizabethan English learn stands side by side with teache in the same signification. Cf. Tottell's Miscellany, p. 129 (Arber):

"I would not have it thought hereby
The dolphin swimmie I meant to teache:
Not to the Phe, but to the Sea;
I Rowe not so farre past my teache."

It is true that the distinction between phonetic and analogical change has always been acknowledged in comparative philology. At the same time it cannot be denied that analogical changes were for a long time treated with a certain disdain and contempt, as deviations from the only course of development then allowed to be truly "organic" and natural, namely, that of gradual phonetic change (hence the epithet "false" so constantly attached to analogy in former times). Amongst those who have recently contributed most towards a more correct evaluation of analogy as a motive power in language, Professor Whitney must be mentioned in particular. In his Grundriss der vergleichenden Grammatik der indogermanischen Sprachen (1893, 1897, 1900), which has formed the completion of Brugman's Grundriss der vergleichenden Grammatik der indogermanischen Sprachen. The only work by another hand (on a large department of the subject) which deserves to be mentioned by the side of Delbrück's studies is the small treatise by Hübschmann on the theory of the cases (Zur Casuslehre, 1873). For the comparative neglect of this field of investigation there are several reasons. The earlier philologists had so much to do in determining the languages which should be included within the Indo-European group, and in organizing the field of research as a whole, that it is not to be wondered at if they were unable to devote much attention to syntax. In the seventies, when attention began to be more directed towards comparative syntax, the remarkable discoveries made by Verner with regard to accentuation, and by Brugman, Collitz and others with regard to the phonology of the Indo-European languages, again distracted attention from the subject. Moreover, the research in itself is infinitely more difficult than that into sounds and forms; for the latter may be carried on by the help of grammars and dictionaries with a comparatively small knowledge of the literature of any individual language, while on the other hand the study of syntax is impossible without a thorough and intimate knowledge of the literature and modes of expression in each separate language. It is not, therefore, matter for wonder that Delbrück has confined himself to the investigation of syntax in a part of the languages whose sounds and forms are discussed by Brugman in the earlier volumes of the Grundriss. To cover the whole ground is beyond the powers of a single man, and there is a great lack of preliminary studies on the syntax of many of the languages.

One of the most difficult problems connected with syntax, but primarily, as it appears, a question of morphology, is the origin of grammatical gender. It cannot be said to be an advantage to the languages which possess it, while languages which, like English, have dropped it except for an occasional metaphor, suffer no loss. Nor is the problem confined to the history of gender in the substantives. Even more perplexing is the introduction of gender into the adjectives, participles, and second persons, which are certainly very old, show no trace of gender; the pronouns of the third person, which are more of the nature of deictic adjectives, generally possess it. To the question how grammatical gender arose in the substantive, the answer was till comparatively recently supposed to be that primitive man was given greatly to personification, endowing inanimate things with life and attributing to them influences benevolent or even dangerous in his lapses from his existence. The answer is not quite satisfactory, for though this tendency to personification, which philologists have perhaps unduly decried or altogether denied, might account for life being attributed to inanimate objects, it hardly explains why some should be treated as masculine and others as feminine. Nor is it true, as has also been suggested, that in the case of the lower animals the generic name for the larger and stronger animals is masculine and that for the smaller or weaker feminine. In both Greek and Latin the wolf
is masculine and the fox feminine, but the lamb or the chicken which the fox robs from the fold or the henroost is rarely feminine, generally masculine. Nor does this explanation account for the mouse in those languages being of the masculine gender, while the ferret or cat which caught them is feminine (γαάη, feles). An explanation which completes the theory of personification, if it does not altogether drive it from the field, has been put forward by Brugmann. In its briefest form this explanation is that gender was attached to certain suffixes because they chanced to occur frequently in words which markedly implied sex. In the Indo-European languages the commonest suffix indicating feminine gender is ḍ. According to this theory it had originally nothing to do with gender, but as some early words for woman or wife ended with this sound it came to be identified with feminine gender. Similarly the ending os in e-stems occurred often in names connected with males and so became identified with the masculine gender. But many stems indicate either gender indifferently, and even the very old sex words father and mother have the same ending. But when masculine and feminine endings have been attached to certain suffixes in this way, how comes it that in one series of stems the neuter should be marked not by an absence of all suffix but by a separate suffix in -m? These are the e-stems, other forms of which have been markedly identified with the masculine gender. As this characteristic, like the others mentioned, goes back apparently to a time before the separation of the Indo-European languages, explanation can hardly pass beyond speculation. It is, however, to be noted that the neuter form of the nominative is phonetically identical with the accusative form of the masculine, and it has been ingeniously argued that such forms were used originally in the accusative, such neutrals not forming the subject to a verb. To the same writer the most plausible explanation of the presence of gender in the adjective is due, viz. that gender began with the deictic pronoun *so “that man,” *sā “that woman,” and that hence it passed to the adjective with which the pronoun was so frequently accompanied. If this explanation be right, analogy has brought into the Indo-European languages the useless multiplication of gender marks in such sentences as the Latin hae pulcras feminae caecae suae, where the feminine gender is indicated no less than four times without any obvious gain over the English These fair women were slain, where grammatical gender is no longer obviously indicated at all.

Closely related to this question is that of the history of the neuter plural, which was first fully treated by Professor Johannes Schmidt of Berlin. The curious construction, most common in ancient Greek, whereby a neuter plural is combined with a singular verb, is now demonstrated to be an archaic survival from the time when the neuter plural was a collective singular. Thus a word like the Latin iugum was a single yoke, the plural iuga, however, which was earlier iugā, was a collection of yokes, with the same final ḍ as is found generally in feminine substantives. The declension ought therefore to have been originally: nominative iugā, genitive iugās, &c., like menās, &c., of the first declension. But as iugum was used in the neuter singular for both nominative and accusative, iugā when it was felt as the corresponding plural, the neuter accusative as well as the singular, while the other cases of the plural were taken over from the masculine o-stems, with which the singular neuter in -o-m was so closely connected. That collective words should be used for the plural is not surprising; the English youth, first an abstract, next a collective, and finally an individual, is a case in point.

For the early history of the syntax of the verb Greek and Sanskrit are important above all other languages, because in them the original forms and the original usages are better preserved than they are elsewhere. And it is in the verb that the great difficulties of comparative syntax present themselves. The noun system is so well preserved in several languages that, when the number of the original cases had once been determined, the sitting of the pro-ethnic usages attaching to each case was tolerably easy, for besides Sanskrit and (to a less extent) Latin, Lithuanian and Slavonic have kept the pro-ethnic case system almost complete. The ideas also which had to be expressed by the cases were on the whole of a very concrete character, so that here the problem was much simplified. On the other hand, the ideas expressed by the forms of the verb are of a much more subtle nature, while the verb system in all languages except Greek and Sanskrit has broken down earlier and more completely than the noun. It is clear that the verb of the original Indo-European language possessed two voices, and forms corresponding to what we call the Indicative, Subjunctive, and Optative moods, and to the Present, Imperfect, Future, Aorist, and Perfect tenses. The imperative mood seems primitively to have been confined to the second person singular, just as the vocative, which, like the imperative is a stem form without suffix, was confined to the singular. The infinitive, as is well known, is in all languages of this system not originally a verbal but a substantival form. The pluperfect, where it has developed, seems to be a mixed form arising from the application of aorist endings to a perfect stem. Thus far the history of the verb system is tolerably clear. But when we attempt to define the original meaning of the moods and of the tenses we pass into a region where, in spite of assiduous investigation in many quarters during recent years, the scanty amount of light thrown on the problem has only served to make the darkness visible. As regards the tenses, at least, it has been shown that without doubt there is no difference in formation between present, future and aorist stems, while the earliest meaning of the perfect was that of a special kind of present expressing either repeated or intensive action or a state. It has also been proved that the original meaning of the aorist is not past in time, and that in fact the only element whereby these languages could express remoteness in time was the augment. The augment seems to have been originally a pronominal deictic particle. Thus, as there was no original pluperfect, as neither perfect nor aorist originally referred to past time, and as the future, except in Lithuanian (with slight traces in Slavonic) and the Indo-Iranian group, cannot be clearly distinguished from the aorist, the system as a method of expressing time absolutely breaks down. The tenses in fact did not originally express the times when the action took place, but the type of action which took place. Thus the Greek imperfect was in the first instance an action which might begin; the Greek aorist, an action which might begin, which might end, or an action, the aorist only the fact that the action had taken place. The action indicated by the aorist might have been of considerable duration, or it might have been begun and ended in a moment; its characteristics in this respect are not in any way indicated by the aorist form, which intimates only that the action is viewed as a completed whole and not as a continuous process. The present system, however, is built up in a great variety of ways (thirty-two according to Brugmann’s enumeration). It is a priori unlikely that such a multiplicity of formations had not originally some reason for its existence, and Delbrück thinks that he has discovered a difference in syntactical value between present and future in Sanskrit. The Sanskrit eka-rādhī, Greek έκαρθή, &c., is regarded as expressing originally an action which consisted of repeated acts of the same nature (iterative), though this iterative meaning frequently passed into an intensive meaning. Present of the type seen in Sanskrit teṣyati, “thirsty,” and Greek χύπον, “am glad” (for *χυπάω), where the -sy of the suffix has modified the first syllable and disappeared, he regards as cursive—i.e. they express continuous action without reference to its beginning or end. Verbs which have regard to the beginning or end of the action he calls terminative, and finds them represented (a) in verbs with -n- suffixes, Sanskrit rāddhi, brum, sets in motion,” thanks to correspondences in Indo-European with Sanskrit gaceti, “goes” (to a definite destination), Greek βλέπω, &c. The roots he classifies as momentary (punctuell) or non-momentary, according as they do or do not express an action which is begun and ended at once.
This method of classification was no doubt suggested in the first instance by the characteristics of the Slavonic verb system. In this system a clear distinction is drawn in nearly all verbs between those which express a process (durative verbs) and those which express a completed action (perfective verbs). When perfective and durative verbs are formed from the same root, the perfective are distinguished from the durative forms (a) by having a preposition prefixed, or (b) by having a different stem formation. Thus in the Old Bulgarian (Old Ecclesiastical Slavonic) to strike (bit) and to strike dead are expressed by the same verb, but in the latter meaning a preposition is found which does not appear in the former, biti (ininitive), “to strike”; u-biti, “to strike dead.” To strike is durative; to strike dead is perfective. As an example of difference of stem formation expressing this difference of meaning, we may quote sestí to sit down (perfective), státí, “to sit” (durative). Verbs with a suffix in -n have often a perfective meaning; cf. the Sanskrit and Greek verbs quoted above. The perfective verbs correspond in meaning to the Greek aorist, and are to be carefully distinguished from perfect forms. The same distinction of meaning is often achieved in other languages also by means of prepositions, e.g. in Latin (Seneca, Epp. xxii. 10), Quid autem ad rem pertineat, quaedam vites, quod evitare non possis? “What does it matter how long you go on avoiding [durative] what you cannot escape [perfective].” From this example, however, it is clear that, though the means employed to make the distinction are different, there is no difference in meaning between such perfective verbs and those classified by Delbrück as terminative. Here, as in many other parts of this study, the ideas are new, and grammatical terminology has not yet sufficiently crystallized, and still leaves something to be desired both in clearness and in precision.

As regards the moods, the difficulty has been to find any connection whereby the functions of one mood could be differentiated from those of the others. It has long been recognized that the difference between indicative and subjunctive is one of meaning and not one of formation; that, e.g., in Sanskrit bharati (3rd sing. pres. indic.), “I shall go,” is morphologically identical with kari, “I may go” (3rd sing. pres. subj.), and that the latter is described as a subjunctive only because of the meaning, and because there exists a dissyllabic form, karíti, which makes the indicative “shall.” Similarly in Greek it is impossible to distinguish morphologically between σαῦω, “I shall shout” (fut. indic.) and σαῦω, “let me check” (1st aor. subj.). Moreover, in the earlier forms of the languages which preserve the moods best (Greek and Sanskrit), the connection syntactically between the indicative and the subjunctive forms is closest. Not only does the future express futurity, but also the determination of the subject to carry out the action expressed, which, in Delbrück’s discussion of the moods, is precisely the point chosen as characteristic of the subjunctive. On the other hand, the present optative differs from the present (and future) indicative and present subjunctive in having a special mood suffix, and in having secondary while they have primary personal endings. Nevertheless its meaning overlaps that of the other forms, and some excellent authorities, like Professor W. W. Goodwin, see in it an indicative, subjunctive and optative only different degrees of remoteness in the same sense, and all three being least in the future and greatest in the optative. Delbrück, however, abides, with slight modifications, by the distinction which he propounded in 1871 that the subjunctive expresses Will and the optative Wish. Here again the problem has not been solved, and it is doubtful how far any definite solution is likely to be arrived at, since there are so many gaps in our knowledge of mood forms. These gaps, owing to the break-up of the system at so early a period, it is hardly probable we shall ever be able to fill it. It is possible, however, to do a great deal more than has yet been done even in the most familiar languages. In the Slavonic period, even now, the facts for the uses of the moods within the two centuries of the classical period are imperfectly known, and it is no exaggeration to say that more has been done in the last hundred years for Sanskrit than has been done in two thousand years of continuous study for Latin or Greek.

A still later addition to the domain of Philology—the study of meaning—presents fewer difficulties, but until recent years has been equally neglected. The study is so recent that the literature of the subject is still extremely small. The only attempts to deal with it on a large scale are M. Bréal’s Essai de Sémantique (1897), now translated into English under the title of Semantics (1900), with a valuable introduction and appendix by Dr Postgate, and M. de la Grasserie’s Essai d’une Sémantique intégrale (1898), a work which deserves mention for its attempt to make a thorough classification and a corresponding terminology for semantic phenomena, but the value of which is much diminished by hasty compilation and imperfect knowledge of many of the languages quoted. From the practical point of view many of the phenomena have been classified in works on rhetoric under the headings of Metaphor, Synecdoche and Metonymy. The psychological principle behind this superficial classification is that of association of ideas. Here, as elsewhere, changes proceed not by accident, but according to definite principles. Here, as elsewhere in language, in history, and the other moral sciences, the particular principle in operation can be ascertained only by beginning with the result and working back. To the user of the work and the meaning much more than in phonetics is this necessarily the case. In phonetics all speakers of the same dialect start with approximately the same sound. But the same combination of sounds which we call a word does not recall the same idea to all persons who use that word. The idea that the phrase railway station calls up in the mind of a Londoner is very different from that which occurs to the mind of a child acquainted only with a wayside station serving the wants of a country village of a few hundred inhabitants. The word herring suggests one idea or train of ideas to the fisherman who catches the fish, another to the merchant who purchases it from the fisherman, a third to the domestic who cooks it, and so on. To members of the same family the same word may often have widely different associations, and, if so, the metaphors for which the word shall be employed will differ in each case.

For the history of meaning it is necessary to have regard to all the forms of association of ideas which psychology recognizes. These are contiguity in place or in time, resemblance and contrast. Contrast, however, as J. S. Mill and Bain have shown, is not a simple form of association, but is evolved partly from contiguity, partly from resemblance. An artificial hollow generally implies also an artificial height made of the materials excavated from the hollow. Hence in most languages some words occur with the meanings which are not to be found in the language. For instance, in English we find the words in use both for a ditch and for a mound fringed by a ditch, the word ditch being, in fact, but a dialectal form of dyke. In Scotland, on the other hand, where earthen mounds and stone walls form more frequent boundaries between fields than in England, the word dyke is now practically limited to elevated boundaries, while ditch is limited to excavated boundaries. Thus the proverb, “February fill dyke,” which in English implies that the February rains will fill the ditches, is often understood in Scotland to mean that in February the snow will be level with the tops of the stone or turf walls. Similarly in Latin Tacitus can say fossas proterae, which can only apply to large excavated holes. While in Greek Xenophon also talks of the ditch (trench) thrown up (τάφρος ἀναβλέπμενη). It is only natural, therefore, that other words with several meanings should be used similarly: moat, originally a mound of earth or peat, has come to mean a big ditch; while, conversely, soldiers in trenches are not so much in ditches, as the word ought to signify, as behind breastworks. Sometimes, when two actions opposed to one another are contiguous, a word seems to change to the exact opposite of its original meaning. Thus the English verb wean, which meant originally to accentuate (to cooked food), has been transferred to the necessary preliminary, to accustom to the breast.

Resemblance may be (1) genuine, and (a) of external appearance, or (b) of other characteristics; or (i) fanciful or analogical. From resemblance in the external appearance of the object, the word gem, which in Latin (gemma) usually means a bud, has
come to mean first a pearl and then by extension of the meaning any precious stone. From the concentric coils which appear in both, the Latin word for a pearl (unio, acc. unionem) appears in English as oyster. Examples where the characteristics are not of external appearance are such as the German kaiser and the Russian tsar, which are descended from Julius Caesar, while the Lithuanian word for king—karalius—is Carolus, i.e. Charlemagne. So in modern Perstam, Xasrer, “Lord,” comes from the Zend proper name Huravah (Chosroes). As already pointed out, the resemblances which have established a connexion between perf and imperfet (properly irrelevant) are in sound only. The same is true of the supposed relation of the verb cut to cutlass, cutler and cutlet. While train oil really means oil in drops like tears (cf. German Thrine), most people connect it with railway trains. The resemblance in some cases is merely in function. Thus, though the fir and the oak have no resemblance one to the other, the word fir is now generally identified with the Latin sequar in etymology (cf. jour and quattour), in the same way as the Latin fugas, “beech,” is with the Greek φυγώ, “oak,” the users of the word having, in the course of their migrations, passed from a land with oaks to a land with firs in the course of time, and picked up the name of the land of oaks in the other. Resemblance as the basis of metaphor has a very widely extended influence on language.

The most numerous and most varied forms of change in meaning depend, however, upon the law of contiguity. Perhaps the commonest of all forms of contiguity is that where the word indicating some accompanying feature or condition replaces the word for the object referred to. In the countries that border the Mediterranean the heat of midday is accompanied and intensified by the dying away of the wind, a characteristic remarked upon by Aeschylus (Agam. 565): “What time upon his noonday couch, windless and waveless sank the sea to rest.” From the Greek word καύσιμον, “burning heat,” arises through Late Latin the English calm, where the absence of wind is the only idea present, that of heat having altogether disappeared. Again, in bugle, which is abbreviated for buglehorn, the word which survives properly means wild ox, and the originally more important element is lost. In a combination like silver bugle the word has gone a stage further; the original meaning of horn has also disappeared. There is no longer any thought of an animal’s horn; the only idea that survives is that of a musical instrument. From the cope or cloak (cape) of St Martin, which was preserved as a sacred relic by the Frankish kings, comes the word chapel. The word was first transferred from the cloak to the holy place wherein it was kept, and hence to similar shrines, and ultimately to any place, not being a church, where prayers were said. A jig was originally not the dance, but the fiddle which supplied the music for the dance. The names of liquors are often replaced by some accommodation as of the place, port, sherry, champagne, or by a qualifying adjective as in brandy, properly “burnt,” from the Dutch brandewijn; or, again, only the less important element of the word is retained as in whisky, literally “water,” for the older usquebaugh, a corruption of Gaelic words meaning the “water of life” (aqua vitae). Replacement of substantives by their accompanying adjectives is common in most languages. One of the most common methods of coinage is that of a word which gives it the name of the place or people whence it comes. Thus we have arras, lawn (from Loire), cravat (Croat), coach from Koes in Hungary, bilboes (both fettlers and swords) from the iron mines of Bilboa in Spain. Equally common are the names of inventors—pinchbeck, tontine, silhouette, guillotine, derrick. In the word cash, which comes indirectly from Latin capsa, “a box,” the thing contained has taken its name from the container. Similarly mortar, “cement,” derives its name from the mortar in which it was mixed, while in box the material (boxwood, L. buxus, Greek, βύχος) has usurped the place of the article made. In leper the disease (Lat. lepra, the rough disease, from Greek λεπρος) has been taken into the name of the sufferer, who was earlier called a leprous man. As a consequence, a new substantive leprosy has to be taken from the adjective to indicate the disease. The various changes in meaning, which are classed together as synecdoche, have their origin in contiguity. Thus we have the species for the genus; the butcher, who properly kills goats only (Old French boeuf), has ousted the flesher. But we have also the genus for the species; corn, as a rule, means in England wheat; in Scotland oats; in America, maize. The individual becomes collective as in corps, navy, body (of men); the collective becomes individual when Latin racemus, “bunch of grapes,” passes into English raisin.” Here would be an instance of the phenomenon already mentioned of metaphorical word-meaning, whereby, e.g. steward, “the styward,” becomes the title of a great officer of the realm and the name of a line of kings; or, on the other side, sox (Latin solidus) passes from the name of a gold coin to that of one of proverbially insignificant value. Here, too, would come many euphemistic uses which are, for the most part, applications of more general terms to avoid the mention of some specific act or object which is unpleasant, as death, murder, bankruptcy, death, &, while metaphorical terms for the same things come under resemblance. These examples do not exhaust the forms of contiguity which appear in language, but they are enough to show how, by the effect of this unceasing association of ideas upon language, aspects of the field which is still calls for investigation before the study of meaning attains the same development as the investigation of the other branches of the history of language.

AUTHORITIES (since 1885).—For methods of Linguistic Study: Paul, Principiun der Praschgeschichte (3rd ed., 1898); Von der Galabertz, Die Sprachwissenschaft (2nd ed., 1901); Strong, Logeman & Wheeler, The History of Language (1891), an adaptation of the ideas of the French lexicographer, M. Paul, in Prinzips der Linguistik (translated as Principles de Linguistique phylogétique (1907). For the Controversy regarding Phonetic Laws: Curtius, Zur Kritik der neuesten Sprachforschung; Brugmann, Zum heutigen Stand der Sprachwissenschaft; Schuchardt, Über die Hauptgesetze; gegen die Junggrammatiker (all in 1885); Tarbell, “Phonetic Law,” in Transactions of American Philological Association for 1886, pp. 1 sqq.; Wechsler, “Gibt es eine phonetische Zeichenart?” (1891); Brugmann, Grundriss der vergleichenden Grammatik der indogermanischen Sprachen (1886–1900). A new edition of the Phonology by Brugmann in 1897, of the stem-formations and inflexion of Nouns, Adjectives, Pronouns and Numerals (1900); the first edition of the Phonology and Morphology, translated into English in four volumes by Wright, Conway and Ross. For Discussion of Cont-
PHILOLOGY

Writing deals, chiefly from the anthropological standpoint, with primitive attempts to record ideas in an intelligible form, e.g. with "knot-signs," "message-sticks," picture-writing and the like. Phonetics covers the whole subject of speech sounds and pronunciation, the organs of speech and national sound systems. Supplementary, from another point of view, to the article Alphabet is a complete series of articles on the letters of the English alphabet. In these articles the history of the individual letters is traced from the Phoenician through Aramaic, Greek and Roman to modern times. All these articles may be read in connexion with a comparative table in the article Alphabet (ad fin.), which shows in parallel columns the earliest equivalents of the modern English letters, i.e. Brahmi, Kharoṣṭhī, oldest Brahmi, cursive Brahmi, the Sanskrit alphabet, the Monastic Kharoṣṭhī, Phoenician, Greek, Latin, Cyrillic and Glagolitic. Another important comparative table of written signs is contained in the article Slavs, showing the various Cyrillic, Glagolitic and Latin letters used by the Slav peoples.

Passing from articles dealing with the method and general subject-matter of philology, the student will find articles on the great families of languages, each with its subordinate articles on special languages and dialects.

1. Indo-European Languages.—Of articles on language-families, the most important is that under the heading Indo-European Languages. This great division, which is dealt with from the comparative standpoint in the second part of the article Philology, is under its own heading treated in detail. The article begins with a sub-classification into two main groups — the so-called (A) centum and (B) stelmat groups — each of which is further divided into four sections. In accordance with this classification there are separate articles on the individual ancient and modern languages and dialects.

A. (1) Greek Language (supplemented by sections under Homer, Dorian, &c.); (2) Latin Language (with Osca Lingua, Igavtime, &c., and articles on the Italic tribes and places, e.g. Venetio, Gaesque); (3) Celtic, &c. Celt (with subsidiary articles); and (4) Teutonic, i.e. Teutonic Languages, Scandinavian Languages, and the like.

The modern descendants of these languages are all further treated separately. Thus following Latin Language is the article Romance Languages, which traces the development of the Latin tongue during its gradual differentiation into Italian, French, Spanish, Rumanian, &c.; while a more detailed account of these will be found under Italian Language; French Language; Spanish Language; Rumanian Language. There is also a special article Provençal Language, dealing with the Romanic speech of southern France. The Teutonic languages are similarly dealt with in detail under English Language (including Anglo-Saxon); Dutch Language; German Language; Scandinavian Language itself includes Icelandic, Norwegian, Swedish, Danish.

B. In the stelmat group of the Indo-European family the four divisions are as follows:

(1) Indo-Iranian or Aryan. This division may be subdivided into (a) Indo-Iranian, treated mainly in the article Persia: Language and Literature (including Zend, Old, Middle and New Persian, and the modern dialects), and (b) Indian. The Indian languages are discussed primarily under Indo-Aryan Languages, which describes the relations of Pāsāca, Sanskrit, Prakrit, and gives a paradigm of the various languages of the three great divisions of India. This central article refers to the separate articles Pāsāca, Sanskrit and Prakrit, which in turn are supplemented by a number of articles on particular languages. Of these reference may be made to Bengali; Bihari; Gujarati and Rajasthani; Hindustani; Khas-Mir; Marathi; Pali. The gipsy languages, which may probably be assigned to the Indo-Iranian division, are described under Gipsies.

(2) The account of Armenian will be found under Armenian Language and Literature.

(3) The Balto-Slavonic Languages. Of these the three comprised in the Baltic group, viz. Lithuanian, Lettish and Old Russian, are described under the heading Lithuanians and Letts. For the Slavonic group, the chief article is Slav: Language, which deals with the elements common to all the Slavonic tongues, with their early history and differentiation. It contains a comparative table of alphabets. It is supplemented by an old Slavonic, and by further information under the headings Russia, Bulgaria, Servia, Poland, Bohemia, Croatia-Slavonia, Slovaks, Slovenes, Sorbs, Kashubes, Poles.

(4) The Albanian dialects are treated under Albania.

2. Semitic Languages.—At the heading of this section stands the article Semitic Languages, supplemented by Hebrew Language, Aramaic Languages, and linguistic sections under Phoenician, Ethiopian, and the like.

3. Hamitic Languages.—The central article in this family is Hamitic Languages, which is supplemented, so far as the Cushitic or Ethiopian group is concerned, by further information in the articles Egypt; Ethiopia; Abyssinia; Somaliland; and, so far as the Libyan group is concerned, by the articles Berbers and Kabyles.

4. The chief feature of the Monosyllabic family is the section Language under China, supplemented again by similar sections in articles on other countries of south-eastern Asia, and by the article Tibeto-Burmese Languages. There is also a language section under Japan which discusses the affinities between Chinese, Korean and Japanese.

5. The Ural-Altaic family is described in outline in the article Ural-Altaic, which gives the general relationships of Turkish, Finno-Ugric, Mongol and Manchu, and of minor subdivisions such as Syriyenian, Mordvinian and Votyak. Turkish is discussed in the article Turks: Language, which deals with Osmanian proper and the Tatar-Turkish languages generally. The article Finno-Ugrian is a comparative survey dealing with the language of the Finns, Lapps, Samoyedes, &c.; while Magyar is treated separately in Hungary: Language. Under Mongols there is a special section Language, discussing the three groups of East Mongol, West Mongol (including Kalmuck) and Buriat.

6. The principal languages of southern India, e.g. Tamil, Malayalam, Kanaarese, Telugu, &c., are dealt with generally under the heading Dravidian; while there is a separate article Tamil, containing a section on their language; and brief notes under the headings Brahui, Telugu, Malayalam, &c.

7 and 8. The scattered languages of the Malay-Polynesian family and other Oceanic peoples are treated principally in the article Malayo, which further information is given under the headings Polynesia; Samoa; Java; Negritos, Battas, &c.

9. The Caucasian family is described chiefly in the article Georgia: Ethnology. Further information will be found in Caucasus: Ethnology.

10. Of the remaining European languages only two need special mention: Basque, which is treated in a special section under the heading Basques; and the lost Etruscan, which is treated under Etruria and Latin Language.

11. The principal languages of southern and central Africa are treated fully under Bantu Languages. There is a brief account of the Bushman language under Bushmen, and of the Hottentot languages under Hottentots.

12. Intermediate African Languages.—Among the numerous languages spoken by the people of the great central belt of the African continent, the most important is the Hausa, described under that heading.

13. America.—The whole question of the languages of the North American Indians is dealt with in the article Indians, North American, which contains an elaborate linguistic paradigm.

Bibliographical information will be found in practically all the above headings. In addition to the most modern authorities there quoted, there will be found in the article Dictionary a very full list of older lexicographical works.

The above summary does not purport to present dogmatically a rigid philological classification. It disregards many problems, and is intended solely to enable the student readily to find the material of which he may be in search.
PHILOMEL—PHILOPONUS

439

PHILOMEL (Fr. Philomèle; Ger. Philomèle or Stahlgiege), a musical instrument similar to the violin, but having four steel, wire strings. The philomel has a body with incisions similar to those of the guitar; therefore, without corner blocks, the outline of the upper lobe forms a wavvy shoulder reminiscent of the viols but more ornate and fanciful. The peg-box sometimes terminates in a fancy head instead of a scroll. The philomel, never used in the orchestra, is the instrument of the divanists, frequently played in Germany with the bowed zither. The accolade of the philomel is the same as for the violin; the timbre is shrill and crystal-like. There is also an alto philomel corresponding to the viol. The bowed melodic is similar to the philomel, and has four steel strings of the same accolade as the violin, but arranged in inverse order; instead of being held like the violin and philomel, under the chin, it is placed on the knees of the performer, so that a hook under the fingerboard rests against the table. (K.S.)

PHILON, Athenian architect of the 4th century B.C., is known as the planner of two important works—the portfolio of the great Hall of the Mysteries at Eleusis and an arsenal at Athens. Of the last we have exact knowledge from an inscription. E. A. Gardner (Ancient Athens, p. 557) observes that it "is perhaps known to us more in detail than any other lost monument of antiquity." It was to hold the rigging of the galleys; and so was contrived that all its contents were visible from a central hall, and so liable to the inspection of the Athenian democracy. (See Athens.)

PHILOPATRIS, the title of a dialogue formerly attributed to Lucian, but now generally admitted to be spurious. Its date and purport have long formed the subject of discussion. The scene is laid at Constantinople. A certain Triphon, who has been converted to Christianity by a hald, long-haired Galilean, who was carried up through the air into the third heaven (an evident allusion to St Paul), meets a friend, Critias, who is in a state of great excitement. Triphon inquires the reason, and the invocati of Zeus by Critias leads to a discussion on paganism and Christianity, in which all the gods proposed by Critias are rejected by Triphon, who finally suggests that Critias should swear by the Trinity. (The sub-title, Ἐ συκαραμάαρος, refers to this "introduction" of Critias in matters relating to Christianity.) Critias goes on to relate how he had been introduced to a gathering of pessimists, who predicted all kinds of disturbances in the empire and defeat at the hands of its enemies. In the meantime a third person appears on the scene with the news that the imperial armies have obtained a glorious victory. The hope is expressed that Babel (Bagdad, the chief city of the caliphs) may soon be destroyed, Egypt subdued (that is, reconquered from the Arabs), and the attacks of the Scythsians (Russians or Bulgarians) repulsed. The whole concludes with thanks to the unknown god of Athens that they have been permitted to be the subjects of such an emperor and the inhabitants of such an empire. The Philopatris was for a long time regarded as an attack upon Christianity; and assigned to the time of Julian the Apostate (emperor 361–363). Chronological indications (e.g. the allusion to a massacre of women in Crete) led Nicolai to attribute the work to Phocas (who died 969), and this view is now generally supported. There being at that time no pagans in Constantinople, the "pessimists" referred to must be Christians—either monks, especially the intimate friends of the patriarch of Constantinople, who, aggrieved at the measures taken by Phocas in regard to the property of the Church, were ready to welcome the defeat of the imperial arms and the ruin of the empire; or harmless visionaries, who claimed to predict the future by fasting, prayer and vigil. In any case, the author, whether he was a sophist commissioned by Phocas to attack the monks, or some professor who hoped to profit by singing the imperial praises, represents the work as a "patriotic" (as the title shows) as opposed to the "unpatriotic." According to another view, which assigns the dialogue to the time of Heraclius (610–641), the author was a Christian fanatic, whose object was to make known the existence of a conventicle of belated pagans, the enemies alike of the Christian faith and the empire; it is doubtful, however, whether such a pagan community, sufficiently numerous to be of importance, actually existed at that date. The object of the first and longer portion of the dialogue was to combat the humanism of the period, which threatened a revival of polytheism as a rival of Christianity.

BIBLIOGRAPHY.—Editions by J. M. Gesner (1715) and C. B. Hase in the Bonn Corpus scriptorum hist. byt. (1839), vol. vii; also included in Jacobitz's edition of Lucian (1839). See R. Rampa, Philopatris. Ein heidnischen Kommente des siebenten Jahrhunderts zu Constantinopel (1894); R. Garnett, "Alms for Oblivion" in Cornhill Magazine (May, 1901); C. Stach, De Philopatride (Cracow, 1894), who shows its late origin by linguistic tests; S. Reinaich in Reue archeologique (1902), vol. i.; B. G. Nebihr, Uber das Alter des Dialog Philopatris (Philologus, vol. 60); and, for further authorities, article by Von Dobschütz in Herzog-Hauck's Realencyclopädie für protestantische Theologie (1904).

PHILOPOEMEN (253–184 B.C.), Greek general, was born at Megalopolis, and educated by the academic philosophers Eudemus and Demophanes or Megalophanes, who had distinguished themselves as champions of freedom. Avoiding the fashionable and luxurious gymnasia, he devoted himself to military studies, hunting and border forays. In 233–2 Philopoemen skirmished with the Macedonians under Cleomenes III, and distinguished himself at Sellasia (222). The next eleven years he spent as a condottiere in Crete. Elected commander of the League's cavalry on his return, he reorganized that force and defeated the Aetolians on the Elean frontier (210). Appointed to the chief command two years later, he introduced heavy armour and close formation for the infantry, and with a well-trained army beat Machanidas of Sparta, near Mantinea. The new "liberator" was now so famous that Philip V of Macedon attempted to poison him. In 202–1 Philopoemen drove Nabis, the Spartan tyrant, from Messene and routed him off Tegae. After another long sojourn in Crete, again he received the command against Nabis. The unsuccessful sea battle, he almost annihilated Nabis's land force near Gythium, but was prevented by the Roman Flamininus from taking Sparta. In 190 Philopoemen protected Sparta, which meanwhile had joined the League and thereupon seceded, but punished a renewed defection so cruelly as to draw the censure of Rome upon his country. At Messene he likewise checked a revolt (189), but when that city again rebelled, in 184, he was captured in a skirmish and promptly executed. His body was recovered by the Achaenians and buried with great solemnity.

Philopoemen's great merit lies in his having restored to his compatriots that military efficiency without which the Achaean League for all its skillful diplomacy could never stand. Towards Rome he advocated a courteous but independent attitude. In politics he was a democrat, and introduced reforms of a popular character (see Achaeans LEAGUE).

Polybius' History (x, xxxii) are the chief authority. These and a special treatise on Philopoemen (now lost) were used by Plutarch (Philopoemen), Pausanias (vii. 49–51), Livy (xxxl–xxxvii), and indebted by Justin (xxx–xxxiv).

PHILOPONUS, JOANNE (John the Grammarian), Greek philosopher of Alexandria, lived in the later part of the 5th and the beginning of the 6th century of our era. The surname Grammaticus he assumed in virtue of his lectures on language and literature; that of Philoponus owing to the large number of treatises he composed. He was a pupil of Ammonius Hermiae, and is supposed to have written the life of Aristotle sometimes attributed to his master. To Philoponus are attributed a large number of works on theology and philosophy. It is said that, though he was a pupil of Ammonius, he was at first a Christian, and he has been credited with the authorship of a commentary on the Mosaic Cosmogony in eight books, dedicated to Sergius, patriarch of Constantinople, and edited by Balthasar Cordelerus in 1620. Other authorities maintain that this, as well as the Disputatio de paschale, was the work of another author, John the Trithelist. It was perhaps this Philoponus who tried to save the Alexandrian library from the caliph Omar after Amu's victory in 639.
PHILOSOPHY

The more certain writings of Philoponus consist of commentaries on Aristotle. These include works on the Physics, the Prior and the Posterior Analytics, the Meteorologica, the De anima, the De generatione et interna and the Metaphysica. These have been frequently edited and are interesting in connexion with the adoption of Aristotelianism by the Christian Church. They soon to some extent were harmonised by Boethius, and are remarkable rather for elaborate care than for originality and insight. He wrote also an attack on Proclus (De aeternitate mundi). Two treatises on mathematics are ascribed to him: A Commentary on the Mathematics of Nicomachus, edited by Hoche (1864 and 1867), and a Treatise on the Use of the Astrolobe, published by Hase. The latter is the most ancient work on this instrument, and its authenticity is rendered almost certain by its reference to the manuscript in his possession.

PHILOSOPHY (Gr. ὕλος, fond of, and σοφία, wisdom), a general term whose meaning and scope have varied very considerably according to the usage of different authors and different ages. It can be best explained by a survey of the steps by which philosophy differentiated itself, in the history of Greek thought, from the idea of knowledge and culture in general. These steps may be traced in the gradual specification of the term. The tradition which assigns the first employment of the Greek word φιλοσοφία to Pythagoras has hardly any claim to be regarded as authentic. There is a passage which states that some of the Pythagoreans at a very early period of the school of Miletus. Diogenes Laërtius attributes the choice of the designation is, in all probability, a piece of etymology crystallized into narrative. It is true that, as a matter of fact, the earliest uses of the word (the verb ἤτοιεντι occurs in Herodotus and Thucydides) imply the idea of the pursuit of knowledge; but the distinction between the σοφία, or wise man, and the ἔλευσθος, or lover of wisdom, appears first in the Platonic writings, and lends itself naturally to the so-called Socratic irony. The same thought is to be found in Xenophon, and is doubtless to be attributed to the historical Socrates. But the word soon lost this special implication. What is of real interest to us is to trace the progress from the idea of the philosopher as occupied with any and every department of knowledge to that which assigns him a special kind of knowledge as his province.

A specific sense of the word first meets us in Plato, who defines the philosopher as one who apprehends the essence or reality of things in opposition to the man who dwells in appearances and the show of sense. The philosophers, he says, "are those who are able to grasp the eternal and immutable"; they are "those who set their affections on that which in each case really exists" (Rep. 486). In Plato, however, this distinction is applied chiefly in an ethical and religious direction; and, while it defines philosophy, so far correctly, as the endeavours to express what that which is perfect and complete in itself is, it fails to express what that is by a sufficient differentiation of the subsidiary inquiries by which this ultimate question may be approached. Logic, ethics and physics, psychology, theory of knowledge and metaphysics are all fused together by Plato in a semi-religious synthesis. It is not till we come to Aristotle—the encyclopaedist of the ancient world—that we find a demarcation of the different philosophic disciplines corresponding, in the main, to that still current. The earliest philosophers, or "physiologers," had occupied themselves chiefly with what we may call cosmology; the question which covers everything for them is that of the underlying substance of the world around them, and they essay to answer the question, so to speak, by simple inspection. In Socrates and Plato, on the other hand, the start is made from a consideration of man's moral and intellectual activity; but knowledge and action are confused with one another, as in the Socratic doctrine that virtue is knowledge. To this correspond the Platonic confusion of logic and ethics and the attempt to substitute a theory of concepts for a metaphysic of reality. Aristotle's methodic intellect led him to separate the different aspects of reality here confounded. He became the founder of logic, psychology, ethics and aesthetics as separate sciences; while he prefixed to all such (comparatively) special inquiries the investigation of the ultimate nature of existence as such, or of those first principles which are common to, and presupposed in, every narrower field of knowledge. For this investigation Aristotle's most usual name is "first philosophy" or, as a modern might say, "first principles"; but there has since been appropriated to it, apparently by accident, the title "metaphysics." "Philosophy," as a term of general application, was not, indeed restricted by Aristotle or his successors to the disciplines just enumerated. Aristotle himself includes under the title, besides mathematics, all his physical inquiries. It was only in the Alexandrian period, as Zeller points out, that the special sciences attained to independent cultivation. Nevertheless, as the mass of knowledge accumulated, it naturally came about that the name "philosophy" ceased to be applied to inquiries concerned with the particulars as such. The details of physics, for example, were abandoned to the scientific specialist, and philosophy restricted itself in this department to the question of the relation of the physical universe to the ultimate ground or author of things. This inquiry which was long called "rational cosmology," may be said to form part of the general subject of metaphysics, or at all events a pendant to it. By the gradual sifting out of the special sciences philosophy thus came to embrace primarily the inquiries grouped as "metaphysics" or "first philosophy." These would,according to the Wolfsian scheme long current in philosophical teaching, be classed either under psychology, or the science of being as such, with its three-branch sciences of (rational) psychology, cosmology and (rational or natural) theology, dealing with the three chief forms of being—the soul, the world and God. Subsidiary to metaphysics, as the central inquiry, stand the sciences of logic and ethics, to which may be added aesthetics, constituting three normative sciences—sciences, that is, which do not, primarily, describe facts, but rather prescribe ends or set forth ideals. It is evident, however, that if logic deals with conceptions which may be considered constitutive of knowledge as such, and if ethics deals with the harmonious realization of human life, which is the highest known form of existence, and psychology inquires into the lighter, that is, into the accidental, and accidental only, and the sciences that are concerned with the use of knowledge, then, the philosophy may now be said to be complete, represents an entirely natural evolution. Similarly, logic, so far as it is an art of thought or a doctrine of fallacies, and ethics, so far as it is occupied with a natural history of impulses and moral sentiments, do neither of them belong, except by courtesy, to the philosophic province. But, although this is so, it is perhaps hardly desirable to deprive ourselves of the use of two terms instead of one. It will not be easy to confuse into so abstract and bloodless a term as "metaphysics" the fuller life (and especially the inclusion of ethical considerations) suggested by the more concrete term "philosophy.”

We shall first of all, then, attempt to differentiate philosophy from the special sciences, and afterwards proceed to take up one by one what have been called the philosophical sciences, with the view of showing how far the usual subject-matter of each is really philosophical in its bearing, and how far it belongs rather to the domain of "science" strictly so called. The order in which, for clearness of exposition, it will be most convenient to consider these disciplines will be psychology, epistemology or theory of knowledge, and metaphysics, then logic, aesthetics and ethics. Finally, the connexion of the last-mentioned with politics (or, to speak more modernly, with jurisprudence and sociology), with the philosophy of history and the philosophy of religion, will call for a few words on the relation of these sciences to general philosophy.
Philosophy and Natural Science.—In distinguishing philosophy from the sciences, it may not be amiss at the outset to guard against the possible misunderstanding that philosophy is concerned with a subject-matter different from, and in some obscure way transcending, the subject-matter of the sciences. Now that psychology, or the observational and experimental study of mind, may be said to have been definitively included among the positive sciences, there is not even the apparent ground which once existed for such an idea. Philosophy, even under its most discredited name of metaphysics, has no other subject-matter than the nature of the real world, as that world lies around us in everyday life, and lies open to observers on every side. But if this is so, it may be asked what function can remain for philosophy when every portion of the field has been explored, and there are none left to be discovered and drawn out and enclosed by specialists? Philosophy claims to be the science of the whole; but, if we get the knowledge of the parts from the different sciences, what is there left for philosophy to tell us? To this it is sufficient to answer generally that the synthesis of the parts is something more than that detailed knowledge of the parts in separation which is gained by the man of science. It is with the ultimate synthesis that philosophy concerns itself; it has to show that the subject-matter which we are all dealing with in detail really is a whole, consisting of articulated members. Evidently, therefore, the relation existing between philosophy and the sciences will be, to some extent, one of reciprocal influence. The sciences may be said to furnish philosophy with its matter, but philosophical criticism reacts upon the matter thus furnished, and transforms it. Such transformation is inevitable, for the parts only exist and can only be fully, i.e., truly, known in their relation to the whole. A pure specialist, if such a being were possible, would be merely an instrument whose results had to be co-ordinated and used by others. Now, though a pure specialist may be an abstraction of the mind, the tendency of specialists in any department naturally is to lose sight of the whole in attention to the particular categories or modes of nature's working which happen to be exemplified, and as a result of this, in their own application and in proportion as this is the case, becomes necessary for their theories to be co-ordinated with the results of other inquirers, and set, as it were, in the light of the whole. This task of co-ordination, in the broadest sense, is undertaken by philosophy; for the philosopher is essentially what Plato, in a happy moment, styled him, ὄντος ὁ τῶν, the man who takes a synoptic or comprehensive view of the universe as a whole. The aim of philosophy (whether fully attainable or not) is to exhibit the universe as a rational system in the harmony of all its parts; and accordingly the philosopher refuses to consider the parts out of their relation to the whole whose parts they are. Philosophy corrects in this way the abstractions which are inevitably made by the scientific specialist, and may claim, therefore, to be the only "concrete" science, that is to say, the only science which takes account of all the elements in the problem, and the only science whose results can claim to be true in more than a provisional sense.

For it is evident from what has been said that the way in which we commonly speak of "facts" is calculated to convey a false impression. The world is not a collection of individual facts existing side by side and capable of being known separately. A fact is nothing except in its relations to other facts; and as these relations are multiplied in the progress of knowledge the nature of the so-called fact is indefinitely modified. Moreover, every statement of fact involves certain general notions and theories, so that the "facts" of the separate sciences cannot be stated except in terms of the conceptions or hypotheses which are assumed by the particular science. Thus mathematics assumes space as an existent infinite, without investigating in what sense the existence or the infinity of this "unfounded, as Kant called it, can be asserted. In the same way, physics may be said to assume the notion of material atoms and forces. These and similar assumptions are ultimate presuppositions or working hypotheses for the sciences themselves. But it is the office of philosophy, as a theory of knowledge, to submit such conceptions to a critical analysis, with a view to discover how far they can be thought out, or how far, when this is done, they refute themselves, and call for a different form of statement, if they are to be taken as a statement of the ultimate nature of the real. The first statement may frequently turn out to have been merely provisionally or relatively true; it is then superseded by, or rather inevitably merges itself in, a less abstract account. In this the same "facts" appear differently, because no longer separated from other aspects that belong to the full reality of the known world. There is no such thing, we have said, as an individual fact; and the nature of any fact is not fully known unless we know it in all its relations to the system of the universe, or, in Spinoza's phrase, sub specie aeternitatis. In strictness, if there are any facts at all, it is the business of philosophy, as science of the whole, to expound the chief relations that constitute its complex nature.

The last abstraction which it becomes the duty of philosophy to remove is the abstraction from the knowing subject which is made by all the sciences, including, as we shall see, the science of psychology. The sciences, one and all, deal with a world of objects, but the ultimate fact as we know it is the existence of an object for a subject. Subject-object, knowledge, or, more widely, self-consciousness with its implications—this unity in duality is the ultimate aspect which reality presents. It has generally been considered, therefore, as constituting in a special sense the problem of philosophy. Philosophy may be said to be the explication of what is involved in this relation, or, in Kantian phraseology, a theory of its possibility. Any would-be theory of the universe which makes its central fact impossible stands self-condemned. On the other hand, a sufficient analysis here may be expected to yield us a statement of the reality of things in its last terms, and thus to shed a light backwards upon the true nature of our subordinate conceptions.

Psychology, Epistemology and Metaphysics.—This leads to the consideration of the main divisions of philosophy—Psychology (q.v.), epistemology (theory of knowledge, Erkenntnistheorie), and metaphysics (ontology; see METAPHYSICS). A special relation has always existed between psychology and systematic philosophy, but the closeness of the connexion has been characteristic of modern and more particularly of English thought. The connexion is not difficult to explain, seeing that in psychology, or the science of mind, we study the fact of intelligence (and moral action), and have, so far, in our hands the fact to which all other facts are relative. From this point of view we may even see a truth in Jacobin's dictum as quoted by Sir W. Hamilton: "Nature conceals God; man reveals God." Nature by itself, that is to say, is insufficient. The ultimate explanation of things cannot be given by any theory which excludes from its survey the intelligence in which nature, as it were, gathers herself up. But knowledge, or the mind as knowing, willing, &c., may be looked at in two different ways. It may be regarded simply as a fact; in which case the evolutions of mind may be traced and reduced to laws in the same way as the phenomena treated by the other sciences. This study gives us the science of empirical psychology, or, as it is now termed, psychology sans phrase. In order to give an adequate account of its subject-matter, psychology may require higher or more complex categories than are employed in the other sciences, just as biology, for example, cannot work with mechanical categories alone, but introduces the conception of development or growth. But the affinities of such a study are manifestly with the sciences as such rather than with philosophy; and the definitive establishment of psychology as an independent science has already been alluded to. Since it has been taken up by specialists, psychology is being established on a broader basis of induction, and with the advantage, in some departments, of the employment of experimental methods of measurement. But it is not of mind in this aspect

1 The divisional office which philosophy here assumes constitutes her the critic of the sciences. It is in this connexion that the meaning of the definition of philosophy as "the science of principles" can best be seen. This is perhaps the most usual definition, and, though vague, one of the least misleading.
PHILOSOPHY

that such assertions can be made as those quoted above. Mind, as studied by the psychologist—mind as a mere fact or phenomenon—grows no inference to anything beyond itself. The distinction between mind viewed as a succession of “states of consciousness” and the further aspect of mind which philosophy considers was very clearly put by Croom Robertson, who also made a happy suggestion of two terms to designate the double point of view: 

We may view knowledge as mere subjective function, but it has its full meaning only as it is taken to represent what we may call objective fact, or is such as is named (in different circumstances) real. This is the first suggestion, which to the psychologist, it is best spoken of by an unambiguous name, and for this there seems none better than Intellence. We may then say that psychology is occupied with the natural function of Intellence, seeking to discover its laws and the conditions of its validity (perception, representative imagination, conception, &c.) according to the various circumstances in which the laws are found at work. Philosophy, on the other hand, is theory of Knowledge (as that which is known).”—Psychology and Philosophy, “Mind” (1883), pp. 15, 16.

The confusion of these two points of view has led, and still leads, to serious philosophical misconception. It is hardly an exaggeration to say that, in the English school since Hume, psychology superseded properly philosophical inquiry. And we find even a thinker with a wider horizon like Sir W. Hamilton encouraging the confusion by speaking of “psychology or metaphysics,” while his lectures on metaphysics are mainly taken up with what belongs in the strictest sense to psychology proper, with an occasional excursion (as in the theory of perception) into epistemology. The distinction between psychology and theory of knowledge was first clearly made by Kant, who repeatedly insisted that the Critique of Pure Reason was not to be taken as a psychological inquiry. He defined his problem as the quid juris or the question of the validity of knowledge, not its quid facti or the laws of the empirical genesis and evolution of intellence (to use Croom Robertson’s phraseology). Since Kant philosophy has chiefly taken the form of theory of knowledge or of a criticism of experience. Not, indeed, a preliminary criticism of our faculties or conceptions such as Kant himself proposed to institute, in order to determine the limits of their application, such a criticism ab extra of the nature of our experience is essentially a thing impossible. The only criticism which can be applied in such a case is the immanent criticism which the conceptions or the varieties exercise upon one another. The organized criticism of these conceptions is really nothing more than the full explication of what they mean and of what experience in its full nature or notion is. This constitutes the theory of knowledge in the only tenable sense of the term, and it lays down, in Kantian language, the conditions of the possibility of experience. These conditions are the conditions of knowledge as such, or, as it may be put, of objective consciousness—a self-consciousness of a world of objects and through them consciousness of itself. The inquiry is, therefore, logical or transcendental in its nature, and does not entangle us in any decision as to the conditions of the genesis of such consciousness in the individual. When we inquire into subjective conditions we are thinking of facts causing other facts. But the logical or transcendental conditions are not causes or even factors of knowledge; they are the statement of its idea. Hence the dispute between evolutionist and transcendentalist rests, in general, on an ignorantio elenchus; for the history of the genesis of an idea (the historical or genetic method) does not contain an answer to—though it may throw light on—the philosophical question of its truth or validity. Speaking of this transcendental consciousness, Kant goes so far as to say that it is not of the slightest consequence whether the idea of it be clear or obscure (in empirical consciousness, not in the transcendental), not even the possibility of the logical form of all knowledge rests on its relation to this apprehension as a faculty or potentiality” (Werke, ed. Hartenstein, iiii. 578 note). Or, if

1 It is true that he afterwards modifies this misleading identification by introducing the distinction between empirical psychology and the phenomenon of mind and inferential psychology or ontology, i.e., metaphysics proper. But he continues to use the terms “philosophy,” “metaphysics,” and “mental science” as synonymous.

we return to the distinction between epistemology and psychology, by way of illustrating the nature of the former, we may take the following summarizing up by Professor James Ward in a valuable article on “Psychological Principles” in Mind (April 1883, pp. 166, 167): “Comparing psychology and epistemology, the latter, on the one hand, is essentially devoid of everything historical, and treats, sub specie aeternitatis, as Spinoza might have said, of human knowledge, conceived as the possession of mind in general.”

Kant’s problem is not, in its wording, very different from that which Locke set before him when he resolved to “inquire into the original, certainty and extent of human knowledge together with the grounds and degrees of belief, opinion and assent.” Locke’s Essay is undoubtedly, in its intention, a contribution to the theory of knowledge. But, because time had not yet made the matter clear, Locke suffered himself to digress in his second book into the psychological question of the origin of our ideas; and his theory of knowledge is ruined by the failure to distinguish between the epistemological sense of “idea” as significant content and the psychological sense in which it is applied to a fact or process in the individual mind. The same confusion runs through Berkeley’s arguments and vitiates his conclusions as well as those of Hume. But appearing with these thinkers as the problem of perception, epistemology widens its scope and becomes, in Kant’s hands, the question of the possibility of experience in general. With Hegel it passes into a completely articulated “logic,” which apparently claims to be the same time a metaphysic, or an ultimate expression of the nature of the real.

This introduces us to the second part of the question we are seeking to determine, namely the relation of epistemology to metaphysics. It is evident that philosophy as theory of knowledge must have for its complement philosophy as metaphysics (ontology) or theory of being. The question of the truth of our knowledge, and the question of the ultimate nature of what we know, are in reality two sides of the same inquiry; and therefore our epistemological results have to be ontologically expressed. But it is not every thinker that can see his way with Hegel to assert in set terms the identity of thought and being. Hence the theory of knowledge becomes with some a theory of human ignorance. This is the case with Herbert Spencer’s doctrine of the Unknowable, which he advances as the result of epistemological considerations in the philosophical prolegomena to his system. Very similar positions were maintained by Kant and Comte; and, under the name of “agnosticism” (q.v.), the theory has popularized itself in the outer courts of philosophy, and on the shifting borderland of philosophy and literature. The truth is that the habit of thinking exclusively from the standpoint of the theory of knowledge tends to beget an undue subjectivity of temper. And the fact that it has become usual for men to think from this standpoint is very plainly seen in the almost universal description of philosophy as an analysis of “experience,” instead of its more old-fashioned designation as an inquiry into “the nature of things.” As it is matter of universal agreement that the problem of being must be attacked indirectly through the problem of knowledge, this substitution may be regarded as an advance, more especially as it implies that the fact of experience, or of self-conscious existence, is the chief fact to be dealt with. But if so, then self-consciousness must be treated as itself real, and as organically related to the rest of existence. If self-consciousness be treated in this objective fashion, then we pass naturally from epistemology to metaphysics or ontology. (For, although the term “ontology” has been as
PHILOSOPHY

behind the subject's representation of it. Hence come the different varieties of a so-called phenomenon. The upholders of such a theory would, in general, deride the term "metaphysics" or "ontology"; but it is evident, none the less, that their position itself implies a certain theory of the universe and of our own place in it, and the establishment of this theory constitutes their metaphysics.

Without prejudice, then, to the claim of epistemology to constitute the central philosophic discipline, we may simply note its liability to be pressed too far. The exclusive preoccupation of men's minds with the question of knowledge during the neo-Kantian revival in the 'seventies of the last century drew from Lotze the caustic criticism that "the sharpening of the knife becomes tiresome, if, after all, we have nothing to cut with it." Stillingfleet's complaint against Locke was that he was "one of the gentlemen of this new way of reasoning that have almost discarded substance out of the reasonable part of the world." The same may be said with greater truth of the devotees of the theory of knowledge; they seem to have no need of so old-fashioned a commodity as reality. Yet, after all, Fichte's dictum holds good that knowledge as knowledge—i.e. so long as it is looked at as knowledge—is, ipso facto, not reality. The result of the foregoing, however, is to show that, as soon as epistemology draws its conclusion, it becomes metaphysics; the theory of knowledge passes into a theory of being. The ontological conclusion, moreover, is not to be regarded as something added by an external process; it is an immediate implication. The metaphysic is the epistemology from another point of view—regarded as completing itself, and explaining in the course of its exposition that relative or practical separation of the individual knower from the knowable world, which it is a sheer assumption to take as absolute. This, not the so-called assumption of the implicit unity of being and thought, is the really unwarrantable postulate; for it is an assumption which we are obliged to retract bit by bit, while the other offers the whole doctrine of knowledge as the continual altering of the self. (Or, if we use another phrase, the continual contact of the subject-matter with the terms or objects of thought.)

Logic, Aesthetics, and Ethics.—If the theory of knowledge thus passes insensibly into metaphysics it becomes somewhat difficult to assign a distinct sphere to logic (q.v.). Ueberweg's definition of it as "the science of the regulative laws of thought" (or "the normative science of thought") comes near enough to the traditional sense to enable us to compare profitably the usual subject-matter of the science with the definition and end of philosophy. The introduction of the term "regulative" or "normative" is intended to differentiate the science from psychology as the science of mental processes or events. In this reference logic does not tell us how our intellects connect themselves as mental phenomena, but how we ought to connect our ideas. If they are to render truth (other than consistency with what we thought before or as agreement with observed fact). Logic, therefore, agrees with epistemology (and differs from psychology) in treating thought not as mental fact but as knowledge, as idea, as having meaning in relation to an objective world. To this extent it must inevitably form a part of the theory of knowledge. But, if we desire to keep by older landmarks and maintain a distinction between the two disciplines, a ground for doing so may be found in the fact that all the main definitions of logic point to the investigation of the laws of thought in a subjective reference—with a view, that is, by an analysis of the operation, to ensure its more correct performance. According to the old phrase, logic is the art of correct thinking. Moreover we commonly find the logician assuming that the process of thought has advanced a certain length before his examination of it begins; he takes his material full-formed from perception, without, as a rule, inquiring into the nature of the conceptions which are involved in our perceptive experience. Occupying a position, therefore, within the wider sphere of the general theory of knowledge, ordinary logic consists in an analysis of the nature of general statement, and of the conditions under which we pass validly from one general statement to another. But the logic of the schools is eked out by contributions from a variety of sources (e.g. from grammar on one side and from psychology on another), and cannot claim the unity of an independent science.

Aesthetics (q.v.) may be treated as a department of psychology or physiology, and in England this is the mode of treatment that has been most general. To what peculiar excitation of our bodily or mental organism, it is asked, are the emotions due which make us declare an object beautiful or sublime? And, the question being put in this form, the attempt has been made in some cases to explain away any peculiarity in the emotions by analysing them into simpler elements, such as primitive organic pleasures and prolonged associations of usefulness or fitness. But, as just psychology in general cannot do duty for a special psychology of knowledge, so it holds true of this particular application of psychology that a mere reference of these emotions to the mechanism and interactive play of our faculties cannot be regarded as an account of the nature of the beautiful. Perhaps by talking of "emotions" we tend to give an unduly subjective colour to the investigation; it would be better to speak of the perception of the beautiful. Pleasure in itself is unqualified, and affords no differentia. In the case of a beautiful object the resultant pleasure borrows its specific quality from the presence of determinations essentially objective in their nature, though not reducible to the categories of science. Unless, indeed, we conceive our faculties to be constructed on some arbitrary plan which puts them out of relation to the facts with which they have to deal, we have a prima facie right to treat beauty as an objective determination of things. The question of aesthetics would then be formulated—What is it in things that make them beautiful, and what is the relation of this aspect of the universe to its ultimate nature, as that is expounded in metaphysics? The answer constitutes the substance of aesthetics, considered as a branch of philosophy. But it is not given simply in abstract terms: the philosophical treatment of aesthetics includes also an exposition of the concrete phases of art, as these have appeared in the history of the world, relating themselves to different phases of aesthetic culture.

Of ethics (q.v.) it may also be said that many of the topics commonly embraced under that title are not strictly philosophical in their nature. They are subjects for a scientific psychology employing the historical method with the conceptions of heredity and development, and calling to its aid, as such a psychology will do, the investigations of all the sociological sciences. To such a psychology must be relegated all questions as to the origin and development of moral ideas. Similarly, the question debated at such length by English moralists as to the nature of the moral faculty (moral sense, conscience, &c.) and the controversy concerning the freedom of the will belong entirely to psychology. If we exclude such questions in the interest of systematic correctness, and seek to determine for ethics a definite subject-matter, the science may be said to fall into two departments. The first of these deals with the notion of duty, and endeavours to define the good or the ultimate end of action; the second lays out the scheme of concrete duties which are deductible from, or which, at least, are covered by, this abstractly stated principle. The second of these departments is really the proper subject-matter of ethics considered as a separate science; but it is often conspicuous by its absence from ethical treatises. However moralists may differ on first principles, there seems to be remarkably little practical divergence when they come to lay down the particular laws of morality. It may be added that, where a systematic account of duties is actually given, the connexion of the particular duties with the universal formula is in general more formal than real. It is only under the head of casuistry (q.v.) that ethics has been much cultivated as a separate science. The first department of ethics, on the other hand, is the branch of the subject in virtue of which ethics forms part of philosophy. As described above, it ought rather to be called, in Kant's phrase, the metaphysic of ethics. A theory of obligation is ultimately found to be inseparable from a metaphysic of personality. The connexion of ethics with metaphysics will be patent as a matter of fact, if it be remembered how Plato's philosophy is summed up in the idea of the good, and how
Aristotle also employs the essentially ethical notion of end as the ultimate category by which the universe may be explained or reduced to unity. But the necessity of the connexion is also apparent, unless we are to suppose that, as regards the course of universal nature, man is altogether an imperium in imperio, or rather (to adopt the forcible phrase) an imprimatur of the purpose and the plan of things. If, on the contrary, we must hold that man is essentially related to what the same writer calls "a common nature," then it is legitimate corollary that in man as intelligence we ought to find the key of the whole fabric. At all events, this method of approach must be truer than any which, by restricting itself to the external aspect of phenomena as presented in space, leaves no scope for inwardness and life and all that, in Lotze's language, gives "value" to the world. The argument ex analogia hominis has often been carred too far; but if a "chief end of man" be discoverable—αρθρίσμων ἀρρητός, as Aristotle wisely insisted—that the ethical end must be determined—then it may be assumed that this end cannot be irreducible to that ultimate "meaning" of the universe which, according to Lotze, is the quest of philosophy. If "the idea of humanity," as Kant called it, has ethical perfection at its core, then a universe which is really organic whole must be ultimately representable as a moral order or a spiritual kingdom such as Leibniz named, in words borrowed from St Augustine, a city of God.

**Philosophy of the State (Political Philosophy), Philosophy of History, Philosophy of Religion.—**In Plato and Aristotle ethics and politics are indissolubly connected. In other words, seeing that the highest human good is realizable only in a community, the theory of the state as the organ of morality, and itself in its structure and institutions the expression of ethical ideas or qualities, becomes an integral part of philosophy. The difficulty already hinted at, which individualistic systems of ethics experience in connecting particular duties with the abstract principle of duty is a proof of the failure of their method. For the content of morality we are necessarily referred, in great part, to the experience crystallized in laws and institutions and to the unwritten law of custom, honour and good breeding, which has become organic in the society of which we are members. Plato's _Republic_ and Hegel's _Philosophie des Rechts_ are the most typical examples of a fully developed philosophy of the state, but in the earlier systems which through prolonged discussion of natural rights and the social contract must be regarded as a contribution to such a theory. Moreover, if philosophy is to complete its constructive work, it must bring the course of human history within its survey, and exhibit the sequence of events as an evolution in which the purposive action of reason is traceable. This is the task of the philosophy of history, a peculiarly modern study, due to the growth of a humanistic and historical point of view. Lessing's conception of history as an "education of the human race" is a typical example of this interpretation of the facts, and was indeed the precursor which stimulated many more elaborate German theories. The philosophy of history differs, it will be observed, from the purely scientific or descriptive studies covered by the general title of sociology. Sociology conceives itself as a natural science elucidating a factual sequence. The philosophy of history is essentially teleological; that is to say, it seeks to interpret the process as the realization of an immanent end. It may be said, therefore, to involve a complete metaphysical theory. Social institutions and customs and the different forms of state-organization are judged according to the degree in which they promote the realization of the human ideal. History is thus represented by Hegel, for example, as the realization of the idea of freedom, or rather as the reconciliation of freedom and nature and the play of historical interests with the stable objectivity of law and an abiding consciousness of the greater whole in which we move. So far as the course of universal history can be truly represented as an approximation to this reconciliation by a widening and deepening of both the elements, we may claim to possess a philosophy of history. But although the possibility of such a philosophy seems implied in the postulated nationality of the universe, many would hold that it remains as yet an unachieved ideal.

There only remains to be briefly noticed the relation of philosophy to theology and the nature of what is called Philosophy of Religion. By theology is commonly understood the systematic presentation of the teaching of some positive or historical religion as to the existence and attributes of a Supreme Being, including his relation to the world and especially to man. But these topics have also been treated by philosophers and religious thinkers, without dependence on any historical data or special divine revelation, under the title of Natural Theology. Natural Theology is specially associated with the Stoic theories of providence in ancient times and with elaborations of the argument from design in the 18th century. But there is no warrant for restricting the term to any special mode of approaching the problems indicated. In the absence of any subject of metaphysical inquiry, no valid distinction can be drawn between natural theology and general metaphysics. The philosophy of religion, on the other hand, investigates the nature of the religious consciousness and the value of its pronouncements on human life and man's relation to the ground of things. Unity, reconciliation, peace, joy, "the victory that overcometh the world"—such, in slightly varying phrases, is the content of religious faith. Does this consciousness represent an authentic insight into ultimate fact, or is it a pitiful illusion of the nerves, born of man's hopes and fears and of his fundamental ignorance? The philosophy of religion assumes the first alternative. The fundamental philosophy of general is the reflective analysis of religious experience, and the religious experience of mankind is prima facie entitled to the same consideration as any other form of conscious activity. The certainties of religious faith are matter of feeling or immediate assurance, and are expressed in the pictorial language of imagination. It becomes the function of philosophy, dealing with these utterances, to relate them to the results of other spheres of experience, and to determine their real meaning in the more exact terms of thought. The philosophy of religion also traces in the different historical forms of religious belief and practice the gradual evolution of what it takes to be the truth of the matter. Such an account may be distinguished from what is usually called the science of religion by the teleological or metaphysical presuppositions it involves. The science of religion gives a purely historical and comparative account of the various manifestations of the religious instinct without pronouncing on their relative truth or value and without, therefore, professing to apply the idea of evolution in the philosophical sense. That idea is fundamental in the philosophy of religion, which therefore can be written only from the standpoint of a constructive metaphysical theory.

It is, indeed, only from the standpoint of such a theory that the definitions and divisions of the different philosophical disciplines adopted in this article can be said to hold good. But those who, like the positivists, agnostics and sceptics, deny the possibility of metaphysics as a theory of the ultimate nature of things, are still obliged to retain philosophy as a theory of knowledge, in order to justify the asserted limitation or impotence of human reason.

**Bibliography.—**The best general histories of philosophy are by J. E. Erdmann, Friedrich Ueberweg and W. Windelband's being probably the freshest in its treatment and point of view. Ed. Zeller's _History of Greek Philosophy_ still holds the field as the best continuous exposition of the subject, but more recent work in the early period is represented by H. Diels and J. Burnet, while Zeller's view of Plato may be said to have been superseded by the later researches of Lewis Campbell, H. Jackson and others. T. Comper's _Greek Thinkers_ is an able, if somewhat diffuse, survey of the philosophical development in Greece. E. W. B. Clough's _Medieval Thought_ and _The History of Christian Doctrine_ is universally treated by Erdmann and Ueberweg, and a useful compendium, written from a Roman Catholic standpoint, is D. Wulf's _History of Medieval Philosophy_ (1900; Eng. trans., 1907). For modern times, in addition to the general histories already named, the works of Kuno Fischer, R. Fahlenkern and H. Höffding, and R. Adamson's _Lectures on the Development of Modern Philosophy,_
PHILOSTRATUS—PHILOXENUS

may be specially mentioned. Writers on the history of philosophy generally prefix to their work a discussion of the scope of philosophy, its divisions and its relations to other departments of knowledge, and the account given by Windelband and Ueberweg will be found specially valuable.

Kayser, Paulsen, O. Klöpe, W. Wundt and G. T. Ladd, deal largely with this subject, which is also treated by Henry Sidgwick in his Philosophy, its Scope and Relations (1902), by Ernest Naville, La Définition de la philosophie (1886). In 1889 the Introductions to the System of Philosophy (1889). A useful work of general reference is J. M. Baldwin’s Dictionary of Philosophy and Psychology (3 vols., 1895-96).

PHILOSTRATUS, the name of several, three or four, of the Greek sophists of the Roman imperial period—(1) Philostratus the Athenian (c. 170-245), (2) his nephew (?) Philostratus of Lemnos (born c. 190), (3) a grandson (?) of (2). Of these the most famous is Philostratus the Athenian, author of the Life of Apollonius Tyana, which he dedicated to Julia Domna, wife of Alexander Severus and mother of Caracalla (see Apollonius of Tyana). He wrote also Βιοὶ Συμφωνίων (Lives of the Sophists), Gymnasticon and Epitasis (mainly of an erotic character). Very little is known of his career. Even his name is doubtful. The Lives of the Sophists gives the praenomen Flavius, which, however, is found elsewhere in connection with Damipus and Synesius. He called him a Lemnian; Photios a Tyrian; he signs himself, however, as an Athenian. It is probable that he was born in Lemnos, studied and taught at Athens, and then settled in Rome (where he would naturally be called atheniensis) as a member of the learned circle with which Julia Domna surrounded herself. He was born probably in 172, and is said by Suidas to have been living in the reign of Philip (244-249). The fact that the author of Apollonius is also the author of the Lives of the Sophists is confirmed by internal evidence. The latter is dedicated to a consul Antonius Gordianus, perhaps one of the two Gordians who were alive in 248. The work is divided into two parts: the first dealing with the recent Sophists, e.g. Gorgias, the second with the later school, e.g. Herodes Atticus.

The Lives are not in the true sense biographical, but rather picturesque impressions of leading representatives of an attitude of mind full of curiosity, alert and versatile, but lacking scientific method. Preferring the external excellence of style and manner to the solid achievements of serious writing. The philosopher, as he says, investigates truth; the sophist embalms it, and takes it for granted.

The Gymnasticon contains interesting matter concerning the Olympic games and athletic contests generally. The Letters breathe the spirit of the New Comedy and the Alexandrine poets; portions of Letter 33 are almost literally translated in Ben Jonson’s Song to Celia, “Drink to me only with thine eyes.” The Letters, as compared to Philostratus the Athenian, is probably the work of Philostratus the Lemnian. It is a popular disquisition on the heroes of the Trojan War in the form of a conversation between a Thracian vine-dresser of the name of Potionius and a Lemnian merchant. Potionius derives his knowledge from the hero Protesilaus, Palamedes is exalted at the expense of Odysseus, and Homer’s unfairness to him is attacked. It has been suggested that Philostratus is here describing a series of heroic paintings in the palace of Julia Domna. His other works are the Elginai (Imagines), ostensibly a description of 64 pictures in a Neapolitan gallery, Goethe, Welcker, Brunn, E. Bertrand and Helling, among others, have held that the descriptions are of actually existing works of art, while Heyne and Friederichs deny this. In any case they are interesting as showing the way in which ancient artists treated mythological and other subjects, and which is seen nowhere in the works of later authors. The work is imitated by the third Philostratus of Lemnos (or by some later sophist) of whose descriptions of pictures 17 remain.

There is great difficulty, due to a confused statement of Suidas, in distinguishing the works and even the personalities of these Philostrati. Reference is there made to Philostratus as the son of Venus, a rhetorician in Nero’s time, who wrote tragedies, comedies and treatments. Suidas thus appears to give to Philostratus the Athenian the work of Hamann or Boessohart. We are indebted to the Lemnian Philostratus, both sophists, living in Rome. See further a full discussion by K. Münch, in Philologus (1897), suppl. xx., pp. 469-557.

Of works bearing the name Philostratus there is a collected edition by A. L. Calandio in Philologus (1893, 1895), Leipzig; a French edition by F. Morel (Paris, 1868) and Olearius (Leipzig, 1700). There are also editions of the Elginai by Schenkl and Reisch (Leipzig, 1902); of the Gymnasticon by Morel; of the Letters by MS., Darenberg (Paris, 1858), Volckmar (Aurich, 1862), and especially Julius Jüthner (1909), with introd., comments and Ger.
Flavian II., who had accepted the decrees of the Council of Chalcedon and was patriarch of Antioch from 408 to 512. The Monophysites had the sympathy of the emperor Anastasius, and were finally successful in ousting Flavian in 512 and replacing him by their partisan Severus. Of Philonexus’s part in the struggle we possess not too trustworthy accounts by hostile writers, such as Theophanes and Theodorus Lector. We know that in 408 he was staying at Edessa; 1 in or about 509, according to Porphryrius of Cesarea, appointed Flavian bishop of Constantinople; and he finally presided at a synod at Sidon which was the means of procuring the replacement of Flavian by Severus. But the triumph was short-lived. Justin I., who succeeded Anastasius in 512, was less favourable to the party of Severus and Philonexus, and in 519 they were both sentenced to banishment. Philonexus was sent to Philippopolis in Thrace, and afterwards to Gangra in Paphlagonia, where he met his death by foul play in 523.

Apart from his redoubtable powers as a controversialist, Philonexus displayed an extensive knowledge of Christian literature. The chief monument of his scholarship—the Philoxenian version of the Bible—is only one of the many pieces of Laborious research that are preserved by the following enumerations of Philonexus’s works: Thessalonian and New Testament writings of Thomas of Harkle and of the New Testament by Thomas of Harkle (both in 616–617), of which the latter at least was based on the work of Philonexus. There are also extant portions of commentaries on the Gospels and other books of the Old Testament, which, according to his practical religious zeal we are able to judge from the thirty homilies on the Christian life and character which have been edited and translated by Budge (London, 1894). In these he holds aloof for the most part from theological controversy, and treats in an admirable tone and spirit the themes of faith, simplicity, the fear of God, poverty, greed, abstinence and unchastity. His affinity with his colleagues in the church, together with the excellence of his style, is also apparent in his homilies on the Gospels. He was the author of several treatises works on the theological subjects and his manner of treatment. As his quotations from Scripture appear to be made from the Peshitta, he probably wrote the homilies before he embarked upon the Philoxenian version. Philonexus’s exegesis is clear and profound, and his style is dignified and his tone in his choice of subjects and his manner of treatment as his quotations from Scripture appear to be made from the Peshitta, it is probably written before he embarked upon the Philoxenian version. Philonexus’s exegesis is clear and profound, and his style is dignified and

PHILBRE—PHLEBITIS

PHILBRE (Lat. philobrem cum, from Gr. φίλοβρεμω, φαλκαί, to love), a drug or other medicinal drink supposed to have the magical properties of exciting love.

PHINEUS, in Greek legend, son of Agenor, the blind king of Salmydessus on the coast of Thrace. He was skilled in the art of navigation, and Apollo had bestowed upon him the gift of prophecy. His blindness was a punishment from the gods for his having revealed the counsels of Zeus to mortals, or for his treatment of his sons by his first wife Cleopatra. His second wife having accused his steps of dishonourable proposals, Phineus put out his eyes, or exposed them to the wild beasts, or buried them in the ground up to their waists and ordered them to be scourged. Zeus offered him the choice of death or blindness. Phineus chose the latter, whereupon Helios (the sun-god), offended at the slight thus put upon him, sent the Heliodors to torment him. In another story, the Argonauts (amongst whom were Calais and Zetes, the brothers of Cleopatra), on their arrival in Thrace found the sons of Phineus half-buried in the earth and demanded their liberation. Phineus refused, and a fight took place in which he was slain by Heracles, who freed Cleopatra (who had been thrown into prison) and her sons, and reinstated them as rulers of the kingdom. Tragedies on the subject of Phineus were written by Aeschylus and Sophocles. These would directly appeal to an Athenian audience, Phineus’s first wife having been the daughter of Orthia (daughter of Erechtheus, king of Athens), who had been driven off by Baucis to his home in Thrace. The punishment of Phineus could hardly be regarded as a just retribution for the insult put upon a princess of the royal house of Athens. Apollodoros ib. 9, 21, iii. 15, 3; Sophocles, Antigone, 966, with Jebb’s notes; Died. Sic. iv. 43, 44; Servius on Aeneid iii. 203; Schol on Apollonius Rhodius, 202; Porph. Hymn. ii. 128.

PHIPS (of Phipps), Sir William (1651–1695), colonial governor of Massachusetts, was born on the 2nd of February 1651, at Woolwich, Maine, near the mouth of the Kennebec river. He was a shepherd until he was eighteen, and then a ship carpenter’s apprentice for four years; worked at his trade in Boston for a year, at this time learning to read and write; and with his wife’s property established a ship-yard on the Sheepscot river in Maine, but soon abandoned it because of Indian disorders. In 1684–1686, with a commission from the British Crown, he searched vainly for a wrecked Spanish treasure ship of which he had heard while on a voyage to the Bahamas; he found this vessel in 1687, and from it recovered £30,000. Of this amount much went to the duke of Albermarle, who had fitted out the second expedition. Phips received £16,000 as his share, was knighted by James II, and was appointed sheriff of New England under Sir Edmund Andros. Poorly educated and ignorant of law, Phips could accomplish little, and returned to England. In 1689 he returned to Massachusetts, found a revolutionary government in control, and at once entered into the life of the colony. He joined the North Church (Cotton Mather’s) at Boston, and was soon appointed by the General Court commander of an expedition against the French in Canada, which sailed in April 1690 and easily captured Port Royal. A much larger expedition led by Phips in May 1691, against Quebec and Montreal ended disastrously. Phips generously bought at their par value, in order to give them credit in the colony, many of the colony’s bills issued for the payment to the expedition. In the winter of 1690 he returned to England, vainly sought aid for another expedition against Canada, and urged with Increase Mather, the colonial agent, a restoration of the colony’s charter, annulled during the reign of Charles II. The Crown, at the suggestion of Mather, appointed him the first royal governor under the new charter. On reaching Boston in May 1692, Phips found the colony in a very disordered condition, and though honest, persevering and indisposed to exact his prerogative at the expense of the people, he was unfitted for the difficult position. He appointed a special commission to try the witchcraft cases, but did nothing to stop the witchcraft mania, and suspended the sittings of the court only after great atrocities had been committed. In defending the frontier he displayed great energy, but his policy of building forts was expensive and therefore unpopular. Having the manners of a 17th-century sea captain, he became involved in many quarrels, and engaged in a bitter controversy with Governor Benjamin Fletcher of New York. Numerous complaints to the home government resulted in his being summoned to England to answer charges. While in London awaiting trial, he died on the 18th of February 1695.

PHLEBITIS (from Gr. φλεμάτω, a vein), inflammation of a vein. When a vein is inflamed the blood in it is apt to form a clot, or thrombus, which, if loosened and displaced from its original position, may be carried as an embolus towards the heart and there be arrested; or it may pass through the cavities of the heart into the lungs, there to lodge and to give rise to alarming symptoms. If the thrombus is formed in the inflamed vein of a pile it may pass as an embolus (see HAEMORRHHOID) into the liver. If an embolus is carried through the left side of the heart it may enter the large vessels at the root of the neck and reach the brain, giving rise to serious cerebral disturbance or
to a fatal paralysis. The thrombus may be formed in gout and rheumatism, or in consequence of stagnation of the blood-current due to slowing of the circulation in various wasting diseases. When a thrombus forms, absolute rest in the recumbent posture is to be strictly enjoined; the great danger is the displacement of the clot. An inflamed and clotted vein, if near the surface, causes an elongated, dusky elevation beneath the skin, where the vein may be felt as a hard cord, the size, perhaps, of a cedar pencil, or a pen-holder. Its course is marked by great tenderness, and the tissue which was drained by the branches of that vein are livid from congestion, and perhaps boggy and pitting with oedema. If, as often happens, the inflamed vein is one of those running conspicuously upwards from the foot—a saphenous vein (σαφής, distinct)—the patient should be placed in bed with the limb secured on a splint in order to protect it from any rough movement. Should the clot become detached, it might give rise to sudden and alarming faintness possibly even to a fatal syncope. Thus, there is always grave risk with an inflamed and clotted vein, and modern surgery shows that the safest course is, when practicable, to place a ligature on the vein upon the heart-side of the clotted piece and to remove the latter by dissection. When, as sometimes happens, the clot is invaded by septic organisms it is particularly liable to become disintegrated, and if parts of it are carried to various regions of the body they may there give rise to the formation of secondary abscesses. In the ordinary treatment of phlebitis, in addition to the insistence on perfect rest and the suppurations may be applied locally, the limb being kept raised. Massage must not be employed so long as there is any risk of a clot being detached. (E. O.)*

PHLEGN, of Tralles in Asia Minor, Greek writer and freedman of the emperor Hadrian, flourished in the 2nd century A.D. His chief work was the Olimpiads, an historical compendium in sixteen books, from the 1st down to the 220th Olympiad (776 B.C. to A.D. 137), of which several chapters are preserved in Photius and Synellus. Two small works by him are extant: On Marzels, containing some ridiculous stories about ghosts, prophecies and monstrous births, but instructive as regards ancient superstitions; On Long-lived Persons, a list of Italians who had passed the age of 100, taken from the Roman censuses. Other works ascribed to Phlegon by Suidas are a description of Sicily, a work on the Roman festivals in three books, and a topography of Rome.

Fragments in C. Müller, Frag. hist. graec. iii.; of the Marzels and Long-lived in O. Keller, Rerum naturalium scriptores, i. (1877); see also H. Windisch, "Phlegon's Androgynorakel in Sillystische Blätter" (1890).

PHLOGOPITE, a mineral belonging to the group of micas (q.v.). It is a magnesium mica, differing from biotite in containing only a little iron; the chemical formula is \[\text{H}_2\text{K}_2\left(\text{Mg}_2\text{Fe}^{2+}\right)\text{Al}_2\text{Si}_3\text{O}_{10}\]. It crystallizes in the monoclinic system, but the crystals are roughly developed. There is a perfect cleavage parallel to the basal plane; the cleavage flakes are not quite so elastic as those of muscovite. Sometimes it is quite colourless and transparent, but usually of a characteristic yellowish-brown colour, and often with a silvery lustre on the cleavage surfaces, hence the trade name "silver amber mica" for some varieties. The name phlogopite is from Gr. πυλογοπος (fiery-looking), the mineral being sometimes brownish-red and coppery in appearance. The hardness is 2-3, and the specific gravity 2.7-2.8-2.85. The optic axial plane is parallel to the plane of symmetry and the axial angle \(\beta=10^\circ\). Phlogopite occurs chiefly as scales and plates embedded in crystalline limestones of the Archean formation. The mica mined in Canada and Ceylon is mainly phlogopite, and is largely used as an insulator for electrical purposes. In Canada it occurs with apatite in pyroxene rocks which are intrusive in Laurentian gneisses, and the crystal forms the principal ore in the phlogopite deposit in Ottawa county in Quebec and near Burgess in Lanark county, Ontario. In Ceylon, the mineral forms irregular veins, rarely exceeding one or two feet in width, traversing granulite, especially near the contact of this rock with crystalline limestone.

(L. J. S.)

PHLOX (Nat. Ord. Polemoniaceae), a genus of about 30 species, mostly perennial hardy plants of great beauty, natives of North America (one occurs in Siberia), with entire, usually opposite, leaves and showy flowers generally in terminal clusters. Each flower has a tubular calyx with five lobes, and a saucer-shaped corolla with a long slender tube and a flat limb. The five stamens are given off from the tube of the corolla at different heights and do not protrude beyond it. The ovary is three-ribbed with one to two ovules in each cell; it ripens into a three-valved capsule. Many of the species and varieties are tall herbs yielding a wealth of bloom throughout the summer and early autumn. These require a deep, rich, and rather heavy loam, and a cool, moist position to flourish.

The dwarf perennial species and varieties, the "moss pinks" of gardens, are charming plants for the rockery and as edging to beds and borders to make the lawn complete. They are tall-growing rose with serrated habit, the branches rooting at the nodes. They succeed in poorer soil, and drier situations than the tall kinds. Seed is seldom produced. Propagation is effected by cuttings in July and early August, placed in a cold frame, and by division of the plants, which should be lifted carefully, and cut into rooted portions as required. The tufted kinds decay in patches in winter if the situation is moist and the weather mild and wet.

Phlox Drummondii and its numerous varieties are half-hardy annuals in Britain. It is a small-growing hairy plant, flowering profusely during the summer months. For early flowering it should be sown in heat in March and April and transplanted out of doors in May. They are hardy, and flower from the beginning of June, but the flowering season is later and shorter.

The tall-growing border phloxes are divided into early and late flowering kinds respectively, the former derived mainly from P. glaberrima and P. sufragosica, and the latter from P. maculata and P. paniculata. The saucer-shaped flowers with cylindrical tubes range from pure white to almost bright scarlet in colour, passing through shades of pink, purple, magenta lilac, mauve and salmon. New varieties are obtained by the selection of seedlings. Owing to the frequent introduction of new kinds, the reader is referred to the current lists published by growers and nurseries. The "moss pinks," P. subulata, and its varieties, are all worthy of a place in the alpine garden.

The varieties are relatively few. The following list includes nearly all the best kinds:

- P. subulata, pink with dark centre; Aloidendronis, rose; annulata, bluish white, tinged with purple; atroldicina, deep lilac; atropurpurea, deep purple; biocarpa and crimson; biocarpa, Deep crimson; compakta, clear rose; Fairy, lilac; G. F. Wilson, mauve; grandiflora, pink, crimson blotch; Little Dot, white, blue centre; Nelon, pure white; Vivid, rose, carmine centre; all these are about 1 ft. high. P. Drummondii, lavender; P. grandiflora, rose, 1 ft.; P. subulata, rose, 6 in.; and P. amoena, rose, 9 in., are also charming alpines.

P. Drummondii varieties come true from seed, but are usually sown in mixture.

PHOCAEA (mod. Fokia or Fokka) an ancient city on the western coast of Asia Minor, famous as the mother city of Marseilles. It was the most northern of the Ionian cities, and was situated on the coast of the peninsula which separates the gulf of Cyme, occupied by Aeolian settlers, from the Hermaean or Cyme, which subsequently extended land and water between two good harbours, Nausathmus and Lampeter (Livvy xxxvii. 31), led the inhabitants to devote themselves to maritime pursuits. According to Herodotus the Phocaeans were the first of all the Greeks to undertake distant voyages, and made known the coasts of the Adriatic, Tyrrhenia and Spain. Arganthonius, king of Tartessus in Spain, invited them to emigrate in a body to his dominions, and, on their declining, presented them with a large sum of money. They employed in constructing a strong wall around their city, a defence which stood them in good stead when Ionia was attacked by Cyrus in 546. Eventually they determined to seek a new home in the west, where they already had flourishing colonies, e.g.

1 It was said to have been founded by a band of emigrants from Rhodes, under the guidance of Cossus, named Phocae and Damon, but it joined the Ionian confederacy by accepting the government of Athenian rulers of the house of Codrus.
Alalia in Corsica and Massilia (mod. Marseilles). A large part of the emigrants proceeded only as far as Chios, returned to Phocaea, and submitted to the Persian yoke. Phocaea continued to exist under the Persian government, but greatly reduced in population and commerce. Though it joined in the Ionian revolt against Persia in 500 it was able to send only three ships to the combined fleet which fought at Lade. But a Phocean took the supreme command. It never again played a prominent part in Ionian history, and is rarely mentioned. In the time of Timur Phujah was a fortress of Sarukhan, but had been previously in Genoese hands. The ruins still visible on the site bear the name of Palaea Fokia, but they are of little interest. The modern town in the immediate neighbourhood, still known as Fokia, was founded by the Genoese in 1421 on account of the rich alum mines in the neighbourhood. It has a fair natural harbour, which is the nearest outlet of the rich district of Menemen. About 1880, while the Gediz Chai was throwing its silt unchecked into the Gulf of Smyrna and gradually filling the navigable channel, there was talk of reviving Fokia as a new port for Smyrna, and connecting it with the Cassaba railway. But, in deference to Smyrneote protests, a new estuary was opened for the Gediz. Fokia has acquired, local importance however as a port of call for coasting steamers, and it is used to some degree as a summer residence by Smyrnites.

(D. G. H.)

PHOCAS, East Roman emperor (602–610), was a Cappadociam of humble origin. He was still but a centurion when chosen by the army of the Danube to lead it against Constantinople. A revolt within the city soon afterwards resulted in the abdication of the reigning emperor Maurice, and in the elevation of Phocas to the throne, which seems to have been accomplished by one of the circus factions against the wish of the troops. Phocas proved entirely incapable of governing the empire. He consented to pay an increased tribute to the Avars and allowed the Persians, who had declared war in 604 under Chosroes II., to overrun the Asiatic provinces and to penetrate to the Bosporus. When the African governor Heraclius declared against him, Phocas was deserted by the starving populace of Constantinopel, and deposed with scarcely a struggle (610). He died in the same year on the scaffold.

PHOCION, Athenian statesman and general, was born about 402 B.C., the son of a small manufacturer. He became a pupil of Plato and in later life was a close friend of Xenocrates. This academic training left its mark upon him, but it was as a soldier rather than as a philosopher that he first came into notice. Under the Athenian generals he gained a name for his courage, as in the ridge of Parnassus (8668 ft.), which traverses the heart of the country, divides it into two distinct portions. Between this central barrier and the northern frontier range of Cnemis (3000 ft.) is the narrow but fertile valley of the Cephissus, along which most of the Phocian townships were scattered. Under the southern slopes of Parnassus were situated the two small plains of Crisa and Anticyra, separated by Mt Ciphis, an offshoot from the main range. Being neither rich in material resources nor well placed for commercial enterprise, Phocis was mainly pastoral. No large cities grew up within its territory, and its chief places were mainly of strategic importance.

The early history of Phocis remains quite obscure. From the scanty notices of Greek legend it may be gathered that an influx of Celts from the Baltic region in the 10th or 9th century B.C. brought them to the region of the Cephissus valley. In the 7th century B.C. they are mentioned as large in population, which was reckoned as Aeolic. It is probable that the country was originally of greater extent, for there was a tradition that the Phocians once owned a strip of land round Daphnis on the sea opposite Euboea, and carried their frontier to Thermopylae; in addition, in early days they controlled the great sanctuary of Delphi. The restriction of their territory was due to the hostility of their neighbours of Bocotia and Thessaly, the latter of whom in the 6th century even carried their raids into the Cephissus valley. Moreover the Dorian population of Delphi constantly strove to establish its independence and about 500 B.C. induced a coalition of Greek states to proclaim a "Sacred War" and free the oracle from Phocian supervision. Thus their influence at Delphi was restricted to the possession of two votes in the Amphictyonic Council.

During the Persian invasion of 480 the Phocians at first joined in the national defence, but by their irresolute conduct at Thermopylae lost that position for the Greeks; in the campaign of Plataea they were enrolled on the Persian side. In 457 an attempt to extend their influence to the head waters of the Cephissus in the territory of Doris brought a Spartan army into Phocis in defence of the "metropolis of the Dorians." A similar enterprise against Delphi in 448 was again frustrated by Sparta, but not long afterwards the Phocians recaptured the sanctuary with the help of the Athenians, with whom they

Though by no means inclined to truce to the Macedonians, as is shown by his protection of the refugee Harpalus and his spirited campaign in defence of Attica in 322, he won the confidence of the conquerors, and in the restricted democracy which Antipater enforced he became the virtual ruler of Athens. Old age, however, was telling on him; when Polyperchon by his proclamation of "freedom" raised a new crisis in 318, Phocion's dilatoriness was interpreted as active treason on Cassander's behalf, and the people, incited by the restored democrats, deposed him from office. Phocion fled to Polyperchon, but was sent back by the latter to be tried at Athens. The assembly, containing numerous slaves and all the city mob, shouted Phocion down and condemned him to death unheard. Not long after, the Athenians decreed a public burial and a statue in his honour.

Phocion's character and policy were throughout inspired by his philosophic training, which best explains his remarkable purity of character and his prudent councils. To the same influence we may ascribe his reserve and his reluctance to co-operate heartily either with the people or with the Macedonian conquerors who put their trust in him; a greater spirit of energy and enterprise might have made him the leader of his country.

Phocion remained famous in antiquity for the pithy sayings with which he used to parry the eloquence of his opponents. Demosthenes called him "the chopper of my periods."

Plutarch (Life of Phocion) draws much good information from Philochorus and Duris (who reproduces Hieronymus of Cardia); his numerous anecdotes are repeated in other works of his and in Aelian of Tralles, Diodorus of Sicily, and Pausanias on Duris. See Holm. Ch. Hist. vol. iii. (Eng. trans., London, 1896).

(M. O. B. C.)

PHOCIS, an ancient district of central Greece (now a department, pop. 62,246), about 625 sq. m. in arca, bounded on the W. by Ozolian Locris and Doris, on the N. by Opuntian Locris, on the E. by Boeotia, and on the S. by the Corinthian Gulf. It is bounded on the N. by a ridge of Parnassus (8668 ft.), which traverses the heart of the country, divides it into two distinct portions. Between this central barrier and the northern frontier range of Cnemis (3000 ft.) is the narrow but fertile valley of the Cephissus, along which most of the Phocian townships were scattered. Under the southern slopes of Parnassus were situated the two small plains of Crisa and Anticyra, separated by Mt Ciphis, an offshoot from the main range. Being neither rich in material resources nor well placed for commercial enterprise, Phocis was mainly pastoral. No large cities grew up within its territory, and its chief places were mainly of strategic importance.

The early history of Phocis remains quite obscure. From the scanty notices of Greek legend it may be gathered that an influx of Celts from the Baltic region in the 10th or 9th century B.C. brought them to the region of the Cephissus valley. In the 7th century B.C. they are mentioned as large in population, which was reckoned as Aeolic. It is probable that the country was originally of greater extent, for there was a tradition that the Phocians once owned a strip of land round Daphnis on the sea opposite Euboea, and carried their frontier to Thermopylae; in addition, in early days they controlled the great sanctuary of Delphi. The restriction of their territory was due to the hostility of their neighbours of Bocotia and Thessaly, the latter of whom in the 6th century even carried their raids into the Cephissus valley. Moreover the Dorian population of Delphi constantly strove to establish its independence and about 500 B.C. induced a coalition of Greek states to proclaim a "Sacred War" and free the oracle from Phocian supervision. Thus their influence at Delphi was restricted to the possession of two votes in the Amphictyonic Council.

During the Persian invasion of 480 the Phocians at first joined in the national defence, but by their irresolute conduct at Thermopylae lost that position for the Greeks; in the campaign of Plataea they were enrolled on the Persian side. In 457 an attempt to extend their influence to the head waters of the Cephissus in the territory of Doris brought a Spartan army into Phocis in defence of the "metropolis of the Dorians." A similar enterprise against Delphi in 448 was again frustrated by Sparta, but not long afterwards the Phocians recaptured the sanctuary with the help of the Athenians, with whom they
had entered into alliance in 454. The subsequent decline of Athenian land-power had the effect of weakening this new connexion; at the time of the Peloponnesian War Phocis was nominally an ally and dependent of Sparta, and had lost control of Delphi.

In the 4th century Phocis was constantly endangered by its Boeotian neighbours. After helping the Spartans to invade Boeotia during the Corinthian War (395–94), the Phocians were placed on the defensive. They received assistance from Sparta in 386, but were afterwards compelled to submit to the growing power of Thebes. The Thebans levied an especial tax upon Phocis, except in the final campaign of Mantinea (362–61), from which they were excluded. In return for this neglect the Thebans fastened a religious quarrel upon their neighbours, and secured a penal decree against them from the Amphictyonic synod (356).

The Phocians, led by two capable generals, Philomelus and Onomarchus, replied by seizing Delphi and using its riches to hire a mercenary army. With the help of these troops the Phocian League at first carried the war into Boeotia and Thessaly, and though driven out of the latter country by Philip of Macedon, maintained itself for ten years, until the exhaustion of the temple treasures and the treachery of its leaders placed it at the mercy of the invaders, who imposed the obligation to restore the temple funds, and the dispersion of the population into open villages—were soon disregarded. In 339 the Phocians began to rebuild their cities; in the following year they fought against Philip at Chaeronea. Again in 335 they took part in the Lamian War against Antipater, and in 279 helped to defend Thermopylae against the Gauls.

Henceforth little more is heard of Phocis. During the 3rd century it passed into the power of Macedonia and of the Aetolian League, to which in 160 it was definitely annexed. Under the dominion of the Roman republic its national league was dissolved, but was revived by Augustus, who also restored to Phocis the votes in the Delphic Amphictyony which it had lost in 346 and enrolled it in the new Achaean synod. The Phocian League is last heard of under Trajan.

PHOCYLIDES, Greek gnomic poet of Miletus, contemporary of Theognis, was born about 560 B.C. A few fragments of his "maxims" have been preserved (chiefly in the Florilegium of Stobaeus), in which he expresses his contempt for the pests and vanities of rank and wealth, and sets forth in simple language his ideas of honour, justice and wisdom. A complete didactic poem (250 hexameters) called Ποίημα νομεντορος or γραμμα, bearing the name of Phocylides, is now considered to be the work of an Alexandrian Christian of Jewish origin who lived between 170 B.C. and A.D. 50. The Jewish element is shown in verbal agreements with passages of the Old Testament (especially the book of Sirach); the Christian by the doctrine of the immortality of the soul and the resurrection of the body. Some Jewish authorities, however, maintain that there are in reality no traces of Christian doctrine to be found in the poem, and that the author was a Jew. The poem was first printed at Venice in 1495, and was a favourite school textbook during the Reformation period.

See fragments and the spurious poem in T. Bergk, Poetarum lyricorum graecorum, vol. ii. 375; J. von der Meden, Der phylologische Gedicht (1843); Phocylides, Poem of Administration, with introduction and commentary by J. B. Fenning, and translation by H. D. Goodwin (Andover, Mass., 1879); F. Susemihl, Geschichte der griechischen Literatur in der Alexandersache (1802), i. 642; S. Krauss (in "Phoeryphylides") in The Jewish Encyclopaedia and E. Scherzer, Hist. of the Jewish People, div. ii., vol. iii., 313–316 (Eng. trans., 1886), where full bibliographies are given. There is an English verse translation by W. Hewett (Watford, 1840), The Perspicue Poems of Phocylides.

PHOEBE, in astronomy, the ninth satellite of Saturn in order of discovery, or the tenth and outermost now known in the order of distance. It was discovered by W. H. Pickering in 1899 by photographs of the stars surrounding Saturn. It is remarkable in that its motion around the planet is retrograde. (See Saturn.)

PHOEBUS (Gr. for "bright," "pure"), a common epithet of Apollo (q.v.). Artemis in like manner is called Phoebe, and in the Latin poets and their modern followers Phoebus and Phoebé are often used simply for the sun and moon respectively.

PHOENICIA, in ancient geography, the name given to that part of the seaboard of Syria which extends from the Eleutherus (Nahr el-Kebir) in the north to Mt Carmel in the south, a distance of rather more than two degrees of latitude. These parts, however, were largely occupied by Phoenicians, the Phocians, and the Phocians lay Aradus and Marathus, and south of Carmel the border sometimes included Dor and even Joppa. Formed partly by alluvium carried down by perennial streams from the mountains of Lebanon and Galilee, and fringed by great sand-dunes which the sea throws up, Phoenicia is covered with a rich and fertile soil. It is only at the mouth of the Eleutherus and at Acre ("Akka") that the strip of coast-land widens out into plains of any size; there is a certain amount of open country behind Beirut; but for the most part the mountains, pierced by deep river-valleys, approach to within a few miles of the sea, and the whole coast is of the narrow type which it had been discovered by the Phoenicians to inhabit the coast; and the purple shell (murex trunculus and brandaris) is still plentiful. The harbours which played so important a part in antiquity are nearly all silted up, and, with the exception of Beirut, afford no safe anchorage for the large vessels of modern times. A few bays, facing towards the north, break the coast-line, and small rocky islands are dotted here and there just off the shore. Sidon, Tyre and Aradus, though now connected with the mainland, were built originally upon islands; the Phoenicians preferred such sites, because they were convenient for shipping and easily defended against attack.

The chief towns of ancient Phoenicia, as we know of them from their literary sources (15th–8th centuries B.C.) and from the inscriptions and the Old Testament documents, were the following: Acco (now Acre or "Akkâ, judged, i. 31), Achzib (now ez-Zib, ibid.), Alhab (in Assyrian Mahalliba, ibid.);—three towns on the coast south of Tyre, Kānâh (Josh. xix. 28), Tyre (Phoen. Ṣor, now Sūr), Zarephath or Sarepta (1 Kings xvii. 9 now Sarafand), Sidon (now Ṣūdâ), Beirut (Biruta in Egyptian, Biruna in the Amarna tablets, now Beirut), Byblos (in Phoen. and Hebr. Gebal, now Jebel), Arka, 80 m. north of Sidon (Gen. x. 17, now Ṭarka), Sin (Alyy, Sinnab, ibid.), Simyra (Gen. x. 18, now Šâmra), Mariath (now Amrit) not important till the Macedonian period, Arvad or Arados (in Phoen. Arwād, now Ru'ud, Gen. x. 18; Ezek. xxviii. 6, 11), the most nearly of the great Phoenician towns, and always famous as a maritime state.

Race and Language.—The Phoenicians were an early offshoot from the Semitic stock, and belonged to the Canaanite branch of it. Curiously enough in Gen. x. Sidon, the "first-born" of Canaan, is classed among the descendants of Ham; but the table of nations in Gen. x. is not arranged upon strict ethnographic principles; perhaps religious antagonism induced the Hebrews to assign to the Canaanites an ancestry different from their own; at any rate the close connexion which existed from an early date between the Phoenicians and the Egyptians may have suggested the idea that both peoples belonged to the same race. The Phoenicians themselves retained some memory of having migrated from older seats on an eastern sea; Herodotus (i. 1; vii. 89) calls it the "red sea," meaning probably the
PHOENICIA

Persian Gulf; the tradition, therefore, seems to show that the Phoenicians believed that their ancestors came originally from Babylonia. By settling along the Syrian coast they developed a strangely un-Semitic love for the sea, and advanced on different lines from the other Canaanites. From them other Canaanites occupied the Lebanon They called themselves Canaanites and their land Canaan; such is their name in the Amarna tablets, Kinaḥi and Kinaḥi; and with this agrees the statement assigned to Hecataeus (Fr. hist. gr. i. 17) that Phoenicia was formerly called Ḫrā, a name which Philo of Byblos adopts into his mythology by making "China who was afterwards called Phoinix" the eponym of the Phoenicians (Fr. hist. gr. iii. 569). In the reign of Antiochus IV. and his successor the coins of Laodicea of Libanus bear the legend "Of Laodicea which is in Canaan"; the Old Testament also sometimes denotes Phoenicia and Phoenicians by "Canaan," and the Aramaeans of north Syria (e.g. the Zenjiri inscr. ibid., Nos. 61-65). They passed through various modifications in the course of time; after leaving the mother country the script acquires a more cursive, showing stylus on the stones from Cyprus and Attica; the tendency becomes more strongly marked at the Punic stage; until in the eco-Punic, from the destruction of Carthage (146 B.C.) to the 1st century A.D., both the writing and the language reached their most distinct form. The language had one form in North Africa till the 5th century A.D. In his sermons St Augustine frequently quotes Punic words.

History.—The Phoenicians, in imitation of the Egyptians, claimed that their oldest cities had been founded by the gods themselves, and that their race could boast of an antiquity of 30,000 years (Africanus in Syncellus, p. 31). Herodotus quotes (ii. 44) a more moderate tradition which placed the foundation of Tyre 2300 years before the flood (Hegy. c. 275). According to Justin (xvii. 3) the Phoenicians, who had long been settled in their land Sidon, founded Tyre in the year before the fall of Troy; possibly the date 1198 B.C. given by Menander of Ephesus (in Jos. Ant. viii. 3, 1 and c. Ap. i. 18) as that from which the era of Tyre begins, may refer to the epoch which Justin mentions. Little certainty, however, can be allowed to these traditional chronologies. It is probable that in remote ages Babylonia exercised a considerable influence upon Syria and its coast towns; but Mr W. L. King has shown that the tradition, which was supposed to connect Sargon I. (c. 3000 B.C.) with the western land and sea, has been misunderstood; it was the sea in the east, i.e. the Persian Gulf, which Sargon crossed (Chronicles concerning Early Bab. Kings, vol. i. ch. 2, 1900).

The extension of the Egyptian empire in the direction of Asia began about 1600 B.C. under Aphiros (Ashmunes, Amasis I.), the founder of the XVIIIth Dynasty, who carried his arms into Syria, and conquered at least Palestine and Phoenicia, the latter being the country called Da-bi on the Egyptian monuments (Müller, As. u. Am. 1100 B.C. Eur. p. 181). Whether the campaign of Thothmes (Tehmontes) I. to the Euphrates produced any lasting results is doubtful; it was Thothmes III. (1503-1449) who repeated and consolidated the earlier conquest, and established Egyptian suzerainty over the petty states of Syria and Phoenicia (see Egyr. History, I.). For this period of Egyptian domination, and before it, between 1400 and 1500 B.C. we have valuable evidence in the Egyptian papyrus Anastasi I. which mentions Kepuna (Gubna, Gebal-Byblos) the holy city, and continues: "Come then to Berytos, to Sidon, to Sarepta. Where is the ford of Nat'-ana (Nahr el-Kâsimiyeh, or a town)? Where is Etu? (Usu, Palatynus?) Another city on the sea is called a haven, D'ar (Tyre) is its name, water is carried to it in boats; it is richer in fish than in sands." But the fullest information about the state of Phoenicia in the 15th and 14th centuries B.C. comes from the Amarna tablets, among which are many letters from the subject princes and the Egyptian governors of Phoenicia to the Pharaoh. It was a time of much political disturbance. The Hittites (q.v.) were invading Syria; nomads from the desert supported the invasion; and many of the local chiefs were ready to seize the opportunity to throw off the yoke of Egypt. The towns of Phoenicia were

1 Cooke, North-Semitic Inscriptions (elsewhere abbreviated NSL), No. 149 B. 8.
2 In this passage "Phoenicians" is a general name for carriers of commerce, not the inhabitants of a particular country. Similarly "Sidonians," "Can. 1896, is raite (perhaps also "Phoenicians") of the Amarna letters. Elsewhere "Phoenicians" are merchants, kidnappers, &c., "Sidonians" are artists; to indicate nationality both names seem to be used differently, e.g. Od. xiii. 272, xiv. 288, xxv. 414.
4 A vocabulary is given in KAT. 1, 652 seq.; see further Böhl, Die Sprache d. Amarnabriefe (1909).

Sprachen 1896; Nakost, Textb. d. North-Semitic Inscriptions (1903), with translations and notes; Landau, Beiträge z. Altertumsk. d. Orients (1899-1906); Lizdbarski, Altert. Texte (1907), pt. i.

joint expedition from Eziongeber on the Gulf of Akaba (strictly Aglab) to Ophir (? on the east coast of Arabia, see OPHIR) for purposes of trade. The list of Hiram's successors given by Josephus indicates frequent changes of dynasty until the time of Ithobal I, priest of Astarte, whose reign (887–855) marks a return to more settled rule. In contrast to Hiram I, king of Tyre, Ithobal or Ethbaal is styled in 1 Kings xvi. 31 "king of the Sidonians," i.e. of the Phoenicians, showing that in the interval the kings of Tyre had extended their rule over the other Phoenician cities. Under Ethbaal further expansion is recorded; Botrys north of Byblus and Azoa in North Africa are said to have been founded by him; the more famous Carthage owed its origins to the civil disorders which followed the death of Metten I. (826), his next successor but one. According to tradition, Metten's son Pygmalion (820–772) slew the husband of his sister Elissa or Dido; whereupon she fled and founded Carthage (q.v.) in Libya (813; Justin xviii. 4–6). At this point Josephus's extracts from Menander come to an end.

From the time of Ethbaal onwards the independence of Phoenicia was threatened by the advance of Assyria. So far back as 1100 B.C. Tiglath-pileser I. had invaded North Phoenicia, and in order to secure a harbour on the coast he occupied Arad (Aradus); but no permanent occupation followed. In the 9th century, however, the systematic conquest of the west began. In 876 B.C. Assur-nazir-pal III. "washed his weapons in the great sea," and exacted tribute from the kings of Tyre, Sidon, Byblus and other cities, including Arad (Keilinschr. Bibliothek, i. 100). The inscriptions of his son Shalmaneser II. mention the taking of tribute from the Tyrians and Sidonians in 846 and again in 849; the Byblians are included at the latter date, and among the kings defeated at Karkar in 854 or 853 was Metten-baar, king of the Arudites (ibid. pp. 141, 143, 173). Thus Shalmaneser completed the conquests of his predecessors on the Phoenician coast, and established a supremacy which lasted for over a hundred years and was acknowledged by occasional payments of tribute.

In 741 Tiglath-pileser III. mentions on his tribute-lists "Hirûn of Tyre"; and here for the first time a piece of native evidence becomes available. The earliest Phoenician inscription at present known (CIS. i. 5 = NSI. No. 11) is engraved upon the fragments of a bronze bowl dedicated by a certain governor of Qarth-hadasht (or Karti-Hadasht, "New City," i.e. Citium), "servant of Hiram king of the Sidonians to Baal of Lebanon." It is to be noted that this Hiram II. was not only king of Tyre, as the Assyrian inscription calls him, but of Sidon too; and further, that by this time Tyre had established itself as the chief city of the coast, and was acknowledged by occasional payments of tribute.

In 741 Punic pirates from Carthage seized the island and occupied it, and the small large of 150 talents of gold (KB. ii. 23). For the period which follows a certain amount of information is furnished by Menander (in Jos. Ant. ix. 14, 2). Eluleaus IX., in Assyrian Lului, who ruled under the name of Pylas, was king of Tyre, Sidon, and other cities at this time (c. 725–690), and at the beginning of his reign suffered from an invasion by Shalmaneser IV. or Salampsos (Jos.); this was probably the expedition against Hoshea of Samaria in 725, "the king of Assyria . . . overran all Phoenicia, but soon made peace with them all and returned back." In the reign of Sargon Pergos Phoenicia seems to have been left alone; but the inhabitants of Citium revolted, showing that the authority of Tyre in Cyprus had grown weak; and Sargon received the submission of seven Cyprian princes, and set up in Larnaca (probably in 700) the triumphal stele now in the Berlin Museum (Schrader, Cuneif. Inschr. and O. T., 2nd ed., vol. ii. p. 85). But Eluleaus, according to Menander, suppressed the revolt of Citium, and early in the reign of Sennacherib joined the league of Philistia and Judah, which had considerable effect upon the cities of Phoenicia (above, Justin xviii. 3). In the Tyrian annals (Jos. c. Ap. i. 18) the reference was probably to the felling of timber in Lebanon for Hiram's temples; Josephus then misinterpreted this by 1 Kings v. 6.

Phoenicia

Divided; Aradus, Simyra, Sidon supported the rebellion; Rib-hadab, the vassal of Byblus, and Abi-melech, king of Tyre, held out for Egypt; but while all the towns made professions of fidelity, they were scheming for their own interests, and in the end Egypt lost them all except Byblus. The tablets which reveal this state of affairs are written in the language and script of Babylonia, and thus show indirectly the extent to which Babylonian culture had penetrated Palestine and Phoenicia; at the same time they indicate the closeness of the relations between the Canaanite towns and the dominant power of Egypt. After the reign of Amenophis IV. (1370–1350) that power collapsed altogether; but new successors in turn recovered it, and Ramses (Rameses) II. reconquered Phoenicia as far as Beirut, and carved three tablets on the rock beside the Nahal el-Kelb to commemorate his victories; under the XIXth and XXth Dynasties this seems to have remained the northern limit of the Egyptian Empire. But in the reign of Ramses III. (c. 1200) great changes began to occur owing to the invasion of Syria by peoples from Asia Minor and Europe, which ended in the establishment of the Philistines on the coast near Ashkelon. The successors of Ramses III. lost their hold over Canaan; the XXIst Dynasty no longer intervened in the affairs of Syria; but Sheshonk (Shishak), the founder of the XXIIInd Dynasty, about 928 B.C. endeavoured to assert the ancient supremacy of Egypt (cf. 1 Kings xvi. 25 sqq.), but his successes were not lasting, and, as we learn from the Old Testament, the power of Egypt became henceforward practically ineffective. Not until 608 did a Pharaoh (Necho) lead an Egyptian army so far north, and he was defeated by Nebuchadrezzar. During the period which elapsed before the rise of the Assyrian power in Syria the Phoenicians were left to themselves. This was the period of their development, and Tyre became the leading city of Phoenicia.

Between the withdrawal of the Egyptian rule in Syria and the western advance of Assyria there comes an interval during which the city-states of Phoenicia owned no suzerain. The history of this period is mainly a history of Tyre, which not only rose to a sort of hegemony among the Phoenician states, but founded colonies beyond the seas (below). From 970 to 772 B.C. the bare outline of events is supplied by extracts from two Hellenistic historians, Menander of Ephesus and Darius (largely dependent upon Menander), which have been preserved by Josephus, Ant. vii. 5, 3 and c. Ap. i. 17, 18. From the data given in these passages we learn that Hiram I., son of Abi-baal, reigned in Tyre from 970 to 956 B.C. He enlarged the island-town to the east, restored and enriched the temples, built up new towns to Hiram (or Melkath or Meqath) and Astarte, founded the feast of the awakening of Hercules in the month Peritius, and reduced the inhabitants of Utica to their allegiance. The Tyrian annals, moreover, allude to the connexion between Hiram and Solomon. Before this time, indeed, the Phoenicians had no doubt lived on friendly terms with the Israelites (cf. Judges v. 17; Gen. xlix. 13); but the two nations seem to have drawn closer in the time of Solomon. 2 Sam. v. 11, which brings David and Hiram together, probably antedates what happened in the following reign. For Solomon's palace and temple Hiram contributed cedar and fir trees as well as workmen, receiving in exchange large annual payments of oil and wine, supplies which Phoenicia must have drawn regularly from Israelite districts (1 Kings v. 9, 11; cf. Ezek. xxvii. 17; Ezr. iii. 7; Acts xii. 20; Jos. Ant. xiv. 10, 6); finally, in return for the gold which he furnished for the temple, Hiram received the grant of a territory in Galilea (Caleb, 1 Kings ix. 10–14).2 This alliance between the two monarchs led to a

1 In Judges x. 12 (cf. v. 6, iii. 3) the Sidonians are mentioned among the oppressors of Israel; but there is no record of any invasion of Israel by the Phoenicians, and the statement is due to the post-exilic editor who introduced generalizations of ancient history into the book of Judges.

2 Jos. Ant. viii. 3, 1 dates the building of Solomon's temple in the 11th year of Hiram, and 450 years after the foundation of Tyre. This gives a Tyrian era which began in 1198–1197 B.C., i.e. at the time when the Philistines settled on the coast of Canaan, an event
in alliance with Egypt and Ethiopia, which aimed at throwing off the oppressive yoke of Assyria as usual, however, the city-states of Phoenicia could not combine even against a common foe, and several broke away from Tyre, so Manander tells us, and sided with Assyria. In the great campaign of 597 B.C. Sennacherib came down upon the revolting provinces; he forced Lulî, king of Sidon, to fly for refuge to Cyprus, took his chief cities, and set up Tuha'lu (Ethisha) as king, imposing a yearly tribute (KB. ii. 91). The blockade of Tyre by sea, significantly passed over in Sennacherib's inscription, is described by Manander. The island-city proved to be impregnable, but it was the only possession left of what had been the extensive kingdom of Elulaues. Sennacherib, however, so far accomplished his purpose as to cause the cities, which had been held by Tyre and Sidon, which had grown into a powerful state.† At Sidon the successor of Ethisha was Abd-milkath; in alliance with a Cilician chief he rebelled against Easarhaddon about the year 678, with disastrous consequences. Sidon was annihilated; Abd-milkath fell into the hands of Easarhaddon, who founded a new Sidon on the mainland, peopled it with foreigners, and called it after his own name. The old name, however, survived in popular usage; but the character of the city was changed, and till the time of Cyrus the kingdom of Sidon ceased to exist (KB. ii. 145 seq., 145; KAT. 88). Tyre also came in for its share of hardship. Elulaues was wounded by Babal, who, in consequence of his alliance with Tirhaka, the Ethiopian king of Egypt, in a rebellion against Assyria. Easarhaddon, on his way to Egypt for the second time, determined to deal out punishment; he blockaded Tyre, and raised earthworks on the shore and cut off the water-supply; but he did not capture the city itself. His monument found at Zenjirli represents the great king holding Baal of Tyre and Tirhaka of Egypt by cords fastened in their lips.‡ There is no evidence, however, that he actually took either of them prisoner. Early in the reign of Assur-bani-pal Tyre was besieged again (668), but Assur-bani-pal succeeded no better than his predecessors. Nevertheless Baal was submitted in the end, along with the princes of Gebal and Arad, Manasseh of Judah, and the other Canaanite chiefs; in the island of Cyprus the Assyrians carried all before them (KB. ii. 149 seq., 160, 173). On his return from the Arabian campaign Assur-bani-pal severely punished the rebellious inhabitants of Ushu (Palaetyrus) and Akko, and transported the survivors to Assyria (ibid. 220). In Phoenicia, as elsewhere, Assyrian rule created nothing and left nothing behind it but a record of barbarous conquest and extortion. An interesting sidelight is thrown upon this period by the list of the Thalassocracies in the Chronicon of Eusebius (p. 226, ed. Schoene), which places the 45 years of the sea-power of Phoenicia at 621 B.C., and the degree of her trade, as much had happened during the absence of the king, to lie between 709, when Cyprus submitted to Sargon, and 640, when Egypt threw off the rule of Assyria. If this dating is correct, and the Phoenician sea-power was at its height during these years, we can understand why Tyre gave so much trouble to the Assyrian kings.†

In the last crisis of the dying power of Assyria the Egyptians for a short time laid hands on Phoenicia; but after their defeat at the battle of Carchemish (609), the Chaldaean Babylonians became the masters of western Asia. Jeremiah's prophecy of the 538 B.C.

The Neo-

Babylonians

are first allusion (xxv. 22) in 604 to the approaching downfall of the kings of Tyre and Sidon and the coast-land beyond the sea, i.e. the Phoenician settlements on the Mediterranean, seems to imply that the Phoenician states recovered some measure of independence; if they did it cannot have lasted long. In 588 Apries (Pharaoh Hophra) made an attempt
to displace the Chaldaean supremacy; he defeated Tyre and Sidon, and terrorized the other cities into submission (Herod. ii. 161; Diod. Sic. i. 68). Some of the Phoenician chiefs, among them Ithobal II., the new king of Tyre, while forced to yield to a change of masters, were bold enough to declare their hostility to the Babylonians. This state of affairs did not escape the vigilance of Nebuchadrezzar. After the fall of Jerusalem he marched upon Phoenicia; Apries withdrew his army, and the siege of Tyre began. For thirteen years the great merchant city held out (585-573; Jos. c. Ap. i. 21; cf. Ezek. xxvi. 1 seq.). Ezekiel says that Nebuchadrezzar and his host had no reward for their heavy service against Tyre, and the presumption is that the city paid a high price for the favours of terms; for Ithobal's generals ends with the close of the 6th century, and the record is subsequently found in Babylon. The king appointed by Nebuchadrezzar was Baal II. (574-564), after whose death a republic was formed under a single suffete or "judge" (shaftî). Josephus (loc. cit.) is again our authority for the changes of government which followed until the monarchy was revived. At length under Hiram III. Phoenicia passed from the Chaldaeans to the Persians (338), and at the same time Amasis (Ahmosi) II. of Egypt occupied Cyprus (Herod. ii. 182). There seems to have been no struggle; the great siege and the subsequent civil disorders had exhausted Tyre, and Sidon took its place as the leader of the Phoenician cities. In his effort for independence under Hanno the Great (538-521), the real founder of its fortunes; the old independence upon Tyre was changed for a mere relation of piety observed by the annual sending of delegates (theopoi) to the festival of Melkarth (Arrian ii. 24; Polyb. xxxi. 20, 12). The disasters and humiliations which befell Tyre during this and the foregoing period might suggest that its prosperity had been seriously damaged. But Tyre always counted for more in commerce than in politics; and in the year 586, just before the great siege, Ezeekiel draws a vivid picture (ch. xxvii.) of the extent and splendour of its commercial relations. Even when cut off from its possessions on the mainland the city itself was not captured; its seafaring trade went on; and though by degrees the colonies were lost, yet the ties of race and sentiment remained strong enough to bind the Phoenicians of the mother-country to their kindred beyond the seas.

Constitution.—At this point it is convenient to mention what little is known about the constitution of the Phoenician states. All Canaanite analogues speak for kingship as the oldest form of Phoenician government. At least the government inscription of the city of Phoenicia itself and in Cyprus is always called king. The royal houses claimed divine descent,† and the king could not be chosen outside their members. His power, however, was limited by the chief and other families, who possessed great influence in public affairs; thus it was possible for war or peace to be decided at Tyre in the king's absence, or at Sidon against his will (Arrian ii. 15 and 16; Curtius iv. 1, 15). The priest of Melkarth at Tyre was the second man in the kingdom. Associated with the prince was a council of elders; such was the case at Gebal (Beyrus) from the earliest times to the latest (Ezek. xxvii. 9); at Sidon this council consisted of 100 members (Diod. iv. 45), perhaps also at Tyre. Inscriptions of the 2nd and 2nd centuries B.C. mention a Rab (chief) in Sidon, Cyprus and Gaulus (Gozo); what his position was it is difficult to say; in the colonies he may have been a district governor. During Nebuchadrezzar's time, a suffete, i.e. the nominal monarchy at Tyre, and the government was administered by a succession of suffetes (judges); they held office for short terms, and in one instance two ruled together for six years. Much later, in the 3rd century B.C., an inscription from Tyre mentions a suffete (NSI. No. 8) without adding more to our knowledge. Carthage, of course, was governed by two suffetes, and these officers are frequently named in connexion with the Carthaginian colonies (NSI. p. 115 seq.); but we must be careful not to draw the inference that Phoenicia itself had any such magistrates. Under the Persians a federal bond was formed comprising Sidon, Tyre and Arados, whose duty it was to contribute 300 triremes to the Persian fleet (Herod. vii. 89),

† So the Babylonians, Canaanites (e.g. in the case of the Nephilim, Gen. vi. 2), Arabs, Greeks, traced the descent of heroic families to gods (Plut., W. R. Smith, Hist. and Myth. of the Heavens, S. I. Curtius' Primitive Sem. Rev. To-day (London, 1902), p. 112 seq.

‡ An inscr. from Tyre may be read, "Abd ba'al chief of the Hundred," NSI. p. 129; Clermont-Ganneau, Recueil d'arch. or. ii. 294 seq.
the lesser towns being under the command of the great cities. Arados presided over three subordinate towns (Arrian ii. 13); Berytus, which had no king of its own, probably formed with Byblius a single kingdom; while Tripolis consisted of a federation of three cities separated by a stadium from each other, and provided a meeting-place for the federal council, which was chiefly occupied in dealing with internal disorders (Diod. iv. 41). But federation on a larger scale was never possible in Phoenicia, for the sense of political unity existing to bind the different states together. Commercial interests dominated everything else, and while these states were, of course, ultimately influenced by civil wars and the great power-loyalty were but feebly felt. On occasion the towns could defend their independence with strenuous courage; the higher qualities which make for a progressive national life the Phoenicians did not possess.

Phoenicia now became part of the fifth satrapy of the Persian Empire, and entered upon a spell of comparative peace and The Persian growing prosperity. Favoured for the sake of Period, 538— their fleet, and having common interests against 332 B. C. Greece, the Phoenicians were among the most loyal subjects of the empire. At this period Sidon occupied the position of leading state; in the fleet her king ranked next to Xerxes and before the king of Tyre (Herod. viii. 28); her situation afforded advantages for expansion which few, if any, small and dependent islands could rival. The city was distinguished by its cosmopolitan character; the satrap resided there when he came to Phoenicia, and the Persian monarch had his paradise outside the walls. In the first half of the 4th century Straton I. (in Phoen. 'Abd-ashart or Bod-ash'tart) was king, c. 374—362. He cultivated friendly relations with Athens, indicated in a decree of proxenia (Michel, Rec. d'inscr. gr. No. 93 = CIG. No. 87); his court was famed for its luxury; and the extent to which phil-Hellenic tendencies prevailed at this time in Sidon is shown by the royal sarcophagi, noble specimens of Greek art, which have been excavated in the necropolis of the city. It was in the reign of Straton that Tyre fell into the hands of Evagoras, king of Cyprus, who opened up suppliant Phoenician with Greek civilization in Cyprus (Isocr. Evag. 62, Panec. 161; Diod. xv. 2). Straton made friends with Nicoles, son of Evagoras, and with him he came to an untimely end through their implication in the great revolt of the satraps, 362 B.C. (see the story of Straton's death in Jerome, adv. Joen. i. 45). A new revolt of Sidon against the Persians took place under King Tennes owing to the insults offered to the Sidonians at the federal diet in Tripolis. With the aid of Nectanebus of Egypt, who had grievances of his own to avenge, the Sidonians carried the rest of Phoenicia with them and drove the satraps of Syria and Cilicia out of the country. Tennes, however, before thePersian king Artaxerxes III. opened up a war, in which the inhabitants to the number of 40,000 are said to have set fire to their houses and perished; Tennes himself was executed after he had served the ends of the great king (346 B.C.; Diod. xvi. 41—45). The last king of Sidon was Straton II. ('Abd- ash'tart, 346—332) before the Persian Empire came to an end.1

Towards the close of the 4th century the Phoenician coins begin to supplement our historical sources (see NUMISMATICS). From the time of Darius the Persian monarchs issued a gold coinage, and reserved to themselves the right of doing so; but they allowed their satraps and vassal states to coin silver and copper money at discretion. Hence Arados, Byblius, Sidon and Tyre issued a coinage of their own, of which many specimens exist. The coins of these cities were more or less, as a rule, stamped with the name of the ruler.2 Thus from the coins of Byblius we learn the names of four kings, 'El-pa'al, 'Az-ba'ul (between 360 and 340 B.C.), Adbal-melech, 'Ain-el, from the coins of the other cities it is difficult to obtain much information. The native inscriptions, however, now become available, though most of them belong to the period which follows, and only a few have been discovered in Phoenicia proper. One of the earliest of these is the inscription of Byblius (CIS. i. 1 = NSI. No. 3), dating from the Persian period; it records a dedication made by Yehaw-milk, king of Gebal, and mentions the name of the king's grandfather, Uri-milk, but the exact dating of the remainder is obscure.

When Alexander the Great entered Phoenicia after the battle of Issus (333 B.C.), the kings were absent with the Persian fleet in the Aegean; but the cities of Arados, Byblius and The Sidon welcomed him readily, the last-named showing Macedonian special zeal against Persia. The Tyrians also offered submission, but refused to allow the conqueror to enter the city and sacrifice to the Tyrian Heracles. Alexander was determined to make an example of the first who should offer opposition, and at once began the siege. It lasted seven months. With enormous toil the king drove out a mole from the mainland to the island and thus brought up his engines; ships from the other Phoenician towns and from Cyprus lent him their aid, and the town at length was forced in July 332; 8000 Tyrians were slain, 30,000 sold as slaves, and only a few notables, the king Azemiloks, and the festal envoy from Carthage who had taken refuge in the sanctuary of Melkarth, were spared (Diod. xvii. 40—46). It is not unlikely that Zech. ix. 2—4 refers to this famous siege. For the time Tyre lost its political existence, while the foundation of Alexandria presently changed the lines of trade, and dealt a blow even more fatal to the Phoenician cities.

During the wars of Alexander's successors Phoenicia changed hands several times between the Egyptian and the Syrian kings. Thus in 312 Tyre was captured from Antigonus by Ptolemy I., the ally of Seleucus; in 287 it passed into the dominion of Seleucus; in 275 again it was captured by Ptolemy II. Philadelphus, and began to recover itself as an autonomous municipality. From the year 275 "the people of Tyre" reckoned their era (CIS. i. 7 = NSI. No. 9, cf. 10). The Tyrian coins of the period, stamped with native, Greek and Egyptian symbols, illustrate the traditional relations of the city and the range of her ambitions. A special interest attaches to these silver tetradrachms and Didrachms (staters and half-staters), because they were used by the Jews for the payment of the temple tax as "shekels of the sanctuary" (NSI. pp. 355, 44).

Among the Phoenician states we know most about Sidon during this period. The kingship was continued for a long time. The story goes that Alexander raised to the throne a member of the royal family, Abdalonymus, who was living in obscure poverty and working as a gardener (Justin xi. 10; Curt. iv. 1; Diod. xvii. 47 wrongly connecting the story with Tyre). In 312 Ptolemy, then master of Phoenicia, appointed his general Philocrates king of the Sidonians, and a decree in honour of this king has been found at Athens (Michel, No. 387, cf. 1261); but he cannot have reigned long. For at the end of the 4th and the beginning of the 3rd century we have evidence of a native dynasty in the important inscriptions of Tabnit, Eshmun-'azar and Bod-ash'tart, and in the series of inscriptions (repeating the same text) discovered at Bostan esth-Shekh near Sidon (NSI. Nos. 4, 5, 6 and App. i.).4 The last-named texts imply that the first king of this dynasty was Eshmun-'azar; his son Tabnith succeeded him; then came Eshmun-'azar II., who died young, then Bod-ash'tart, both of them grandsons of Eshmun-'azar I. With Bod-ash'tart, so far as we know, the dynasty came to an end, say about 250 B.C.; and it is not unlikely that the Sidonians reckoned an era of independence from this event (NSI. p. 95 n.).

Of the other Phoenician cities something is known of the history of Arados. Its era seems to have begun in 250 B.C., when it probably became a republic or free city. While the rest of Phoenicia passed under the

---

1 The naval expedition against Greece 480—449 and Sparta 396—387, as described by Thucydides, was fitted out by Phoenicia (see PERSIA. Ancient History, for the whole of this section).

2 Justin xviii. 3 tells a story about Tyre during this period: the Persian king wanted to make the wars with the Persians so unbearable that the Phoenicians, who rose and massacred their masters; one Straton alone escaped and was afterwards made king. The reference to the Persians is obvious, but some modern scholars believe that this Straton must refer to one of the sieges by the Assyrians or Chaldaeans, and, as Meyer suggests (Enzy. Bib. col. 3760), may be derived from the story of Abdalonymus of Sidon mentioned below.

3 See especially E. Babelon, Les Pierres Achéménides, and cf. NSI. No. 149.

4 The date of this dynasty has been much disputed; but the reference to "the lord of kings" in the great inscr. of Eshmun-'azar (line 18) points to the Ptolemaic period, for the Persian monarch is always styled "king of kings." The interpretation of many details of the inscr. from Bostan esth-Shekh is still uncertain.
rule of Ptolemy II. and his successors between 281 and 197, Aradus remained in the kingdom of the Seleucids, who greatly favoured the city and increased its privileges (Strabo xvi. 2, 13; Polyb. v. 68). But its subject-towns availed themselves of the political changes of the period. In 226 the Aradians helped their allies the Phoenicians from Tyre to secure a coinage bearing the heads of the Ptolemies, and later on Karne asserted its independence in the same way; but in the end the Aradians recovered their supremacy. Diodorus records a barbarian and Jewish rising by the Aradians, almost with their arms, to destroy Marathus, which was frustrated by the pity and courage of an Aradian fisherman (xxxiii. 5). At last in the time of Tigranes, the Armenian holder of the kingdom of the Seleucids, or soon afterwards, the city was probably attached to the Armenian king, and its land, with that of Simyra, was parcelled out among the Aradians (Strabo xvi. 2, 12). Akko issued coins of its own down to 276 B.C., if the reckoning was from the Seleucid era (312 B.C.). In 200 B.C. the city was conquered by the city of Sidon, and called Potlemis (Polyb. iv. 37; Strabo xvi. 2, 25; cf. Acts xxi. 7). Laodicea of Libanus was founded by Seleucus Nicator on the plain south-east of Hemea (Jomtv) in the region of the upper Orontes, and became an important city; its coins of the 2nd century B.C. bear the interesting legend in Phoenician, "Of Laodicea which is in Canaan" (NSJ. p. 349 seq.). Another Laodicea "by the sea" (ad mare), also of Seleucid foundation, is probably to be identified with the ruined site called Umm el-Awâmid, near the coast between Tyre and Akko; several Phoenician inscriptions have been found there (e.g. CJS., i. 7 = NSJ. No. 9; Clermont Ganneau, Revue, t. vi.).

After the death of Antiochus IV. Epiphanes in 164 B.C., revolts and adventurers made their appearance in many parts of Syria, heralding the collapse of the kingdom of the Seleucids. Berytus was destroyed by the usurper Trypho in 140 B.C. Tyre in 120 and Sidon in 111 received complete independence, and afterwards, Byblus and Tripolis fell into the hands of "tyrants" (Strabo xvi. 2, 18; Jos. Ant. xiv. 3, 2), and Arab robbers plundered their territories from strongholds in the Lebanon. From 83-69 B.C. the entire kingdom was held by the Armenian Tigranes.

At last in 64 B.C. Pompey arrived upon the scene and established order out of chaos. Phoenicia was incorporated into the Roman province of Syria; Aradus, Sidon, Tyre and Tripolis were confirmed in their rights of self-government and in the possession of their territories. In 14 B.C. Augustus rebuilt Berytus as a Roman colony and stationed two legions there; later on Potlemis, Tyre and Sidon received confirmed colonial status. Under the beneficent government of Rome the chief towns prospered and extended their trade; but the whole character of the country underwent a change. During the Macedonian period Greek influences had been steadily gaining ground in Phoenicia; relations with the Greek world grew closer; the native language fell into disuse, and from the beginning of the Roman occupation Greek appears regularly in inscriptions and on coins, though on the latter Phoenician legends do not entirely vanish till the 2nd century A.D.; while the extent to which Hellenic ideas penetrated the native traditions and mythologies is seen in the writings of Philo of Byblus. For the purposes of everyday life, however, the people spoke not Greek, but Aramic. As elsewhere, the Roman rule tended to obliterate characteristic features of national life, and under it the native language and institutions of Phoenicia became extinct.

Navigation, Trade, Colonies.—The Phoenicians were essentially a seafaring nation. Fearless and patient navigators, they ventured into regions where no one else dared to go, and, always with an eye to their monopoly, they carefully guarded the secrets of their trade routes and discoveries, and their knowledge of winds and currents. At the beginning of the 7th century B.C. a Phoenician fleet is said to have circumnavigated Africa (Herod. iv. 42). To the great powers Phoenician ships and sailors were indispensable; Sennacherib, Psammetichus and Necho, Xerxes, Alexander, and later on, employed them for their trade routes and sea-fights. Even when Athens had developed a rival navy, Greek observers noted with admiration the discipline kept on board the Phoenician ships and the skill with which they were handled (Xen. Oec. viii.): all the Phoenician vessels from the round merchant-boat (γαλακτός)—after which the island of Gaulus, now Gozo, near Malta was called—to the great Tarshish-ships, the "East-Indiamen" of the ancient world, excelled those of the Greeks in speed and equipment. As E. Meyer points out, the war between the Greeks and the Persians was mainly a contest between the sea-powers of Greece and Phoenicia. At Rome did Phoenicia first rise to be a power in the Mediterranean? We are gradually approaching a solution of this obscure problem. Recent discoveries in Crete (p. n.) have brought to light the existence of a Cretan or "Minoan" sea-power of remote antiquity, and it is clear that a great deal of what used to be described as Phoenician must receive quite a different designation. The Minoan sea-power was at last broken up by invaders from the north, and a Carian rule became dominant in the Aegean (Herod. i. 171; Thucyd. i. 4, 8). It was a time of disorder and conflict due to the immigation of new races into the ancient seats of civilization, and it synchronized with the weakening of the power of Egypt in the countries which bordered on the eastern Mediterranean. This was in the 12th century B.C. The Tyrian trader saw that his opportunity was come, and the Aegean lay open to his merchant vessels. Where much is still obscure, all that seems certain is that the antiquity of Phoenicia as a sea and trading power has been greatly exaggerated both in ancient and in modern times; the Minoan power of Cnosus preceded it by many centuries; the influence of Phoenicia in the Aegean cannot be carried back much earlier than the 12th century B.C., and, comparatively speaking, it was "foreign, late, sporadic."

A vivid description of the Phoenicians' trade at the time of Tyre's prosperity is given by Ezekiel (xxvii. 12-25), and it shows to what an extent Tyre was independent of foreign trade, and how far Tyre was able to live by itself, but by land as well. It was they who distributed the produce of the world through the wares of Egypt and Babylonia (Herod. i. 1). From the lands of the Ephratures and Tigris regular trade-routes led to the Mediterranean with trading-stations on the way, several of which are mentioned by Ezekiel (xxvii. 23). In Egypt the Phoenician merchants soon gained a foothold; they alone were able to maintain a profitable trade in the anarchic times of the XXIIInd and XXIIIInd Dynasties (825-650 B.C.), when all other foreign merchants were frightened away. Though there were never any regular colonies of Phoenicians in Egypt, the Tyrians had a quarter of their own in Memphis (Herod. i. 112). The Arabian caravan-trade in perfume, spices and incense passed through Phoenician hands on its way to Greece and the West (Herod. iii. 107); these articles of commerce were mainly produced not in Arabia, but in East Africa and India, and the trade had its centre in the wealthy state of Sheba in Yemen. Between Israel and Phoenicia the relations naturally were close; the former provided certain necessary of life, and received in exchange articles of luxury and splendour (Ezek xxvii. 16-18).2 Israelite housewives sold their homespun to Phoenician peddlars (Prov. xxxi. 24 R.V.M.); in Jerusalem Phoenician merchants and money-lenders had their quarter (Zeph. i. 11), and after the Return we hear of Tyrians selling fish and all manner of ware in the city (Neh. xiii. 16), and introducing other less desirable imports, such as foreign cults (Isa. liv. 11). The Phoenician words which made their way into Greek at an early period indicate the kind of goods in which the Phoenicians traded with the West, or made familiar through their commerce; the following are some of them—χαραδὶς, χεῖτας, βέσος, δόθην, μίθρα, νάβα, κέρος, φόκα, μνῆ, παλατικής, βαπτίζεις. Another valuable article of commerce which the Phoenicians brought into the market was amber. They can hardly have fetched it themselves from the Baltic or the North Sea; it came to them by two well-marked routes, one from the Baltic to the Adriatic, the other up the Rhine and down the Rhone. A deposit of amber has also been found in the Lebanon, and perhaps the Phoenicians worked this and concealed its origin.

1 Burrows, Discoveries in Crete (1907), 140 seq. It may be noted that the traditional or conjectural dates based upon the list of the Thol-selector raised by Price does not agree with the 22nd century B.C. See Professor John L. Myres's essay referred to above, § iii. (4).
2 See Eupeolus (140-100 B.C.) quoted by Alexander Polyhistor, who, in a supposed letter from Solomon to the king of Tyre, mentions the food-supplies required by the Tyrians and procured from Palestine (Fr. Hist. Gr. iii. 226).
The Phoenician colonies were all supposed to have been founded from Tyre: with regard to the colonies in Cyprus and north Africa this was undoubtedly true. Cyprus possessed resources of timber and copper which could not fail to tempt the keen-eyed traders across the water, who made Cition (from Kittim, the name of the original non-Semitic inhabitants) their chief settlement, and thence established themselves in Ialium, Tamassus, Lapethus, Larnaka, Qarth-hadashi (Karti-hadasti) and other towns. In the inscriptions of the 4th to 3rd centuries, the Phoenician potentiates in the island call themselves "kings of Kittion and Idalion" (NSI. pp. 55-80). But the Phoenician rule was not so ancient as used to be supposed. At an early period Greeks from the south coast of Asia Minor had settled in Cyprus before the Phoenicians founded any colonies there; and it is noticeable that in the Assyrian tribute-lists of the latter half of the 7th century (KB. ii. pp. 149, 241) not one of the ten Cyprian kings mentioned appears to be Phoenician. Menander states (Jos. Ant. i. 14, 2) that the kings of Tyre ruled over Cyprus at the close of the 8th century; but a clear proof that the Phoenician rule was neither ancient nor uninterrupted is given by the fact that the Cyprian Greeks took the trouble to invent a Greek cuneiform character (Cyprite) modelled on the Phoenician.

Homer represents the Phoenicians as present in Greek waters for purposes of traffic, but not as settlers (U. xxiii. 744). They occupied trading-stations on some of the Aegean islands and on the Isthmus of Corinth. One of their objects was the collection of murex, of which an enormous supply was needed for the dyeing industry; specially famous was the purple of the Laconian waters, the isles of Elisian of Ezek. xxvii. 7. But a great deal of what was formerly assigned to Phoenician influence in the Aegean at an early period—pottery, ornaments and local myths—must be accounted for by the vigorous civilization of ancient Crete. In the Greek world the Phoenicians made themselves heartily detested; their characteristic passion for gain (θηλοχρωματος, Plato, Rep. iv. 435 E.) was not likely to irritate them with those who were compelled to make use of their services while they suffered from their greed.

Farther west in the Mediterranean Phoenician settlements were planted first in Sicily, on the south coast, at Heraclea or Ras Melqarth; the islands between Sicily and Africa, Melita (Malta) on account of its valuable harbour, Gausus and Cossura were also occupied (Diod. v. 12); and a beginning was made with the colonization of Sardinia and Corsica; but farther west still, and on the Atlantic coasts to the right and left of the straits, more permanent colonies were established. It was the trade with Tarshish, the Greek term for the Phoenicians, that provided rich resources for them, and the Phoenicians themselves, as the Phoenicians, which contributed most to the Phoenicians' wealth; for in this region they owned not only profitable fisheries, but rich mines of silver and other metals. The profits of the trade were enormous; it was said that even the anchors of ships returning from Spain were made of silver (Diod. v. 35). From Gadeira (Punic Gdër, Lat. Gades, now Cadiz), the town which they built on an island near the mouth of the Guadalquivir, the Sidonian ships ventured farther on the ocean and drew tin from the mines of north-west Spain or from the richer deposits in the Cassiterides, i.e. the Tin Islands. These were discovered to be, not a part of Britain as was imagined at first, but a separate group by themselves, now known as the Scillies; hence it is improbable that the Phoenicians ever worked the tin-mines in Cornwall.

The rich trade with Spain led to the colonization of the west. Strabo dates the settlements beyond the Pillars of Hercules soon after the Trojan War (i. 3, 2), in the period of Tyre's first expansion. Lixus in Mauretania, Gades and Utica, are said to have been founded, one after the other, as far back as the 12th century B.C.

Most of the African colonies were no doubt younger; we have traditional dates for Aozia (885-855) and Carthage (813). A large part of north-west Africa was colonized from Phoenicia; owing to these first settlers, and after them to the Carthaginians, the Phoenician language became the prevailing one, just as Latin and Arabic did in later times, and the country assumed quite a Phoenician character.

In the days of Tyre's greatness her power rested directly on the colonies, which, unlike those of Greece, remained subject to the mother-city, and paid tithes of their revenues to its chief god, Melqarth, and sent envoys annually to his feast. Then at the beginning of the 8th century B.C. the colonial power of Tyre began to decline; on the mainland and in Cyprus the Assyrians gained the upper hand; in the Greek islands the Phoenicians had already been displaced to a great extent by the advancing tide of Dorian colonization. But as Tyre decayed in power the colonies turned more and more to Carthage as their natural parent and protector. The Phoenicians never lost the advantage of location over Carthage, that was always in favour of Carthage the advantage of situation over far-away Tyre; the traditional bonds grew lax and the ancient dues ceased to be paid, though as late as the middle of the 6th century Carthage rendered tithes to the Tyrian Melqarth. And the mother-country cherished its claims long after they had lost reality; in the 2nd century B.C., for example, Sidon stamped her coins with the legend, "Mother of Kambê (i.e. Carthage), Hippo, Kiton, Tyre" (NSI. p. 352).

Manufacturers, Inventions, Art.—From an early date the towns of the Phoenician coast were occupied, not only with distributing the merchandise of other countries but with working with their own; especially purple-dyeing and textile fabrics (II. vi. 39), the art of metal work and elaborately artistic objects (II. Od. iv. 615 seqq., xiv. 458 sqq.), and glass-work, which had its seat at Sidon. The iron and copper mines of Cyprus (not Sidon, as Homer implies, Od. xv. 424) furnished the ore which was manufactured into various objects for the market (II. vi. 39). The Phoenicians devised the vessels and the making of them, the art of glass-making, in which the Phoenicians, no doubt merely because Phoenician traders brought the products into the market. But dyeing and embroidery probably came from Babylon in the first instance; glass-making seems to have been borrowed from Egypt; the invention of arithmetic and of weights and measures must be laid to the credit of the Phoenicians. The ancients believed that the Phoenicians invented the use of the alphabet (e.g. Pliny, N.H. v. 13, cf. vii. 57; Lucan, Bell. Civ. iii. 220 seqq.); but it is unlikely that any genuine tradition on the subject existed, and though the Phoenician theory has found favour in modern times it is open to much question. The Phoenicians cannot be said to have invented any of the arts or industries, as the ancient world imagined; but what they did was something meritorious: they developed them with singular skill, and disseminated the knowledge and use of them.

The art of Phoenicia is characterized generally by its dependence upon the arts of the Mediterranean East. Throughout the whole line of its own, and borrowed freely from foreign, especially Egyptian, models. Remains of sculpture, engraved bronzes and gems, show clearly the source to which the Phoenician artists went for inspiration. In bronze and in precious stones and the vase, it is said that the Phoenicians were the first in the 4th century B.C., Egyptian influence and then Babylonian or Asiatic influence is predominant, but the national element is strongly marked; while in the second, Greek influence has obtained the ascendency: but the influence of the Phoenicians is much less obtrusive. Throughout these periods works of art, such as statues of the gods and sarcophagi, were imported direct at first from Egypt and afterwards mainly from Rhodes. The entire style of sarcophagi and mummy-cases, painted with colours and ornamented with carvings in low relief; towards and during the Greek period the contours of the body begin to be marked more clearly on the cover. The finest sarcophagi which have been preserved in the near east (the Imperial Museum, Constantinople) are not Phoenician at all, but exquisite specimens of Greek art. The Phoenicians spent much care on their burial-places, which have furnished the most important...
PHOENICIA

monuments left to us. The tombs are subterranean chambers of varied and often irregular form, sometimes arranged in two stories, sometimes only one level deep, and in some cases two or more. Sometimes a mere perpendicular shaft led to these excavations, at a later date stairs were constructed down to the chambers. The dead were buried either in the floor (often in a sarcophagus), or, according to the stricter form of the cult, in the body or cardia of the sarcophagus. The sarcophagi were up and covered with slabs, and occasionally cippi (Phoen. maszobiteh) were set up to mark the spot. The great sepalchral monuments, popularly called magazhá, i.e. "spindles," also belong to the mortuary art of Amorites. These stones of the passage to the tomb are adorned with lions at the base and with roofs of pyramidal shape. Besides busts and figurines, which belong as a rule to the Greek period, the sepulchral objects usually found are copper pitchers, glass-ware, tesselae and gems. Of buildings which can be called architectural few specimens now exist on Phoenician soil, for the reason that for ages the inhabitants have used the ruins as convenient quarries. Of course remains of the great sanctuary of Melqarth at Tyre; a few traces of the temple of Adonai near Byblos were discovered by Renan, and a peculiar mausoleum, Burj Bezaq, is still to be seen near Amrit; recent excavations at Botan (Sheikh Sidon) near Sidon have uncovered parts of the enclosure or foundations of the temple of Eshmun (NSI, p. 401); the conduits of Ras el-Ain, south of Tyre, are considered to be of ancient date. With regard to the plan and design of a Phoenician temple, it is probable that it was similar to those of the temple at Jerusalem, and the probability is confirmed by the remains of a sanctuary near Amrit, in which there is a cella standing on a raised platform and a portico before it, just as in the other buildings in an Egyptian style. The two pillars before the porch of Solomon's temple (1 Kings vii. 21) remind us of the two pillars which Herodotus saw in the temple of Melqarth at Tyre (Herodotus vii. 88). The temple of Paphos and Hierapolis (see W. R. Smith, Rel. of Sem. p. 468 seq.).

Religion.—Like the Canaanites of whom they formed a branch, the Phoenicians connected their religion with the great powers and the human and animal deities of the Semitic peoples. They therefore possessed a god of war, with one in particular supreme over the rest. It seems, however, that at one time on some of them acquired a more extended character; thus Ba'al or El became god of Man, owner of earth and sea, the god of the earth's inhabitants and tilling. The name Ba'al or Elal'ath of such and such a place, a title which was used not only by the Canaanites, but by the Arameans (Be'el) and Babylonians (Bel) as well. There was no one particular god called Baal; the name Baal was given to a number of deities, including the deity as owner or mistress; and the same is the case with Milk or Melk, Adon, 'Amma, which mean king, lord, mother. The god himself was named or had no name. Occasionally a god took his name from the place in which he lived (Melkib), which again means merely "king of the city"; similarly among the Arameans the Ba'al or Ba'al of Harran was the moon-god Sin. As each city or district had its Baal, the author of its fertility, the "husband" (a common meaning of ba'al) of the land which he fertilized, so there were many Ba'als, and the Old Testament writers could allude to the Ba'al of the neighbouring Canaanites. Sometimes the god received a distinguishing attribute which indicated an association not with any particular place, but with some special characteristic; the most common forms are Baal-hammâkin, the chief deity of Phoenician north Africa, perhaps the glowing Baal, the god of the sun, of Baal of the sun. The latter deity was widely venerated throughout the North-Semitic world; his name, which does not appear in the Phoenician inscriptions before the 3rd century B.C., implies perhaps a more universal conception of deity than that of the earlier days. The worship of the female along with the male principle was a strongly marked feature of Phoenician religion. To judge from the carving on the bone ointment boxes, that one beloved of all the other deities, times a mere perpendicular shaft led to these excavations, at a later date stairs were constructed down to the chambers. The dead were buried either in the floor (often in a sarcophagus), or, according to the stricter form of the cult, in the body or cardia of the sarcophagus. The sarcophagi were up and covered with slabs, and occasionally cippi (Phoen. maszobiteh) were set up to mark the spot. The great sepalchral monuments, popularly called magazhá, i.e. "spindles," also belong to the mortuary art of Amorites. These stones of the passage to the tomb are adorned with lions at the base and with roofs of pyramidal shape. Besides busts and figurines, which belong as a rule to the Greek period, the sepulchral objects usually found are copper pitchers, glass-ware, tesselae and gems. Of buildings which can be called architectural few specimens now exist on Phoenician soil, for the reason that for ages the inhabitants have used the ruins as convenient quarries. Of course remains of the great sanctuary of Melqarth at Tyre; a few traces of the temple of Adonai near Byblos were discovered by Renan, and a peculiar mausoleum, Burj Bezaq, is still to be seen near Amrit; recent excavations at Botan (Sheikh Sidon) near Sidon have uncovered parts of the enclosure or foundations of the temple of Eshmun (NSI, p. 401); the conduits of Ras el-Ain, south of Tyre, are considered to be of ancient date. With regard to the plan and design of a Phoenician temple, it is probable that it was similar to those of the temple at Jerusalem, and the probability is confirmed by the remains of a sanctuary near Amrit, in which there is a cella standing on a raised platform and a portico before it, just as in the other buildings in an Egyptian style. The two pillars before the porch of Solomon's temple (1 Kings vii. 21) remind us of the two pillars which Herodotus saw in the temple of Melqarth at Tyre (Herodotus vii. 88). The temple of Paphos and Hierapolis (see W. R. Smith, Rel. of Sem. p. 468 seq.).

Religion.—Like the Canaanites of whom they formed a branch, the Phoenicians connected their religion with the great powers and the human and animal deities of the Semitic peoples. They therefore possessed a god of war, with one in particular supreme over the rest. It seems, however, that at one time on some of them acquired a more extended character; thus Ba'al or El became god of Man, owner of earth and sea, the god of the earth's inhabitants and tilling. The name Ba'al or Elal'ath of such and such a place, a title which was used not only by the Canaanites, but by the Arameans (Be'el) and Babylonians (Bel) as well. There was no one particular god called Baal; the name Baal was given to a number of deities, including the deity as owner or mistress; and the same is the case with Milk or Melk, Adon, 'Amma, which mean king, lord, mother. The god himself was named or had no name. Occasionally a god took his name from the place in which he lived (Melkib), which again means merely "king of the city"; similarly among the Arameans the Ba'al or Ba'al of Harran was the moon-god Sin. As each city or district had its Baal, the author of its fertility, the "husband" (a common meaning of ba'al) of the land which he fertilized, so there were many Ba'als, and the Old Testament writers could allude to the Ba'al of the neighbouring Canaanites. Sometimes the god received a distinguishing attribute which indicated an association not with any particular place, but with some special characteristic; the most common forms are Baal-hammâkin, the chief deity of Phoenician north Africa, perhaps the glowing Baal, the god of the sun, of Baal of the sun. The latter deity was widely venerated throughout the North-Semitic world; his name, which does not appear in the Phoenician inscriptions before the 3rd century B.C., implies perhaps a more universal conception of deity than that of the earlier days. 1

1 Cf. Hannibal's oath to Philip of Macedon; besides the named deities he invokes the gods of the land and earth, and of the sea and meadows and waters (Polyb. vii. 9).

This is well brought out by G. F. Hill, Church Quarterly Rev. (April, 1888), pp. 141-44, who specially emphasizes the evidence of the Phoenician inscriptions. 2

2 "To the lord 'El, which Ba'al-shillem . . . vowed," &c.; Clermont-Ganneau, Rocueil, v. 376.

3 "I am to hand that causes horror" (see p. 48) of Dan. xii. 11, xi. 31, &c., is an intentional disfiguration of Gen. 2:12.

4 The name has been found on an important Aramaic inscr., from North Syria, dating c. 800 B.C., in which Zakir, king of Harrar, was called "res, kesh, lord, first-born" of his god Be-shalamin (Pogon, Inst. sém. de la Syrie, 1908).

Sacrifice, Objects and Images. — The objects and images worshipped at the temple, which consisted of a court of inclosure and a roofed shrine with a portico or pillared hall, were of some interest to the historian. Among the most prominent was the sacred stone, probably the symbol of Astarte, as on the Roman coins of Byblos (illustrated in Rawlinson, Phoenicia, 146). Perrot et Chipiez, Hist. de l'art, iii. 66; see also Ohnefalsch-Richter, Cyprus, pl. lvi., the image of Minerva, etc., aalla, and also the "inhabitants" of the sacred pole (ashtarab), an invaluable feature of a Canaanite sanctuary, was usual in a Phoenician temple (ibid. pp. 50 seq.). The

PHOENIX

457

The mythological tradition of the Phoenix is found in various ancient cultures, primarily Greek and Egyptian. The bird is often associated with the sun, immortality, and resurrection. In Greek mythology, the Phoenix is said to have lived for 500 years, then burned itself to ashes, only to rise again from these ashes. In Egyptian mythology, the phoenix is associated with the sun god Ra.

The Phoenix was also known in ancient China, where it was considered a symbol of filial piety and longevity. The bird was said to live for 1,000 years before dying, but then it would rise again from its own ashes.

The phoenix is also mentioned in the Bible, particularly in the book of Revelation, where it is described as a bird rising from the dead.

The phoenix is often depicted in art and literature as a symbol of rebirth and renewal. It is also a symbol of the soul, as it is believed to be able to ascend to the heavens.

The phoenix is mentioned in various other cultures and texts, including the Hindu Vedas, the Islamic Qur'an, and the Chinese I Ching.

In modern times, the phoenix has been adopted as a symbol of rebirth by various organizations and movements, including the Phoenix Rising Project, which aims to help individuals and communities recover from crisis.

Bibliography:

1. An excellent and critical account of Philo's work is given by Lagrange, Etudes sur les rel. sém. (2nd ed., 1905), ch. xi.

2. Some other ancient accounts may be here referred to. That ascribed to Hecataeus, in the judgment of C. G. Gobet (Mennoance, 1883), stolen from Herodotus by a late forger. The poem of the Jew Ezekiel quoted by Eusebius (Praeph. et. ix. 29, 30) appears to be the phoenix (ibid. 14). Herodotus (i. 39) first mentions a song which, according to the poem on the phoenix ascribed to Laotamius, accompanies the rising sun. The bird is often spoken of in Latin poetry, and is the subject of an idyll by Claudian. See A. Schmitz, Collect. Oedip. ii. 11, 12; Tertullian, De resur. carnis, c. 13; Clemens Rom. Epip. ad Corinthios, i. 25 and the (? Clementine) Apostolical Constitutions, v. 7.
from Arabia, delighting the gods with his fragrance and rising from the sinking flames of the morning glow, was enough to suggest most of the traits materialized in the classical pictures of the phoenix. That the benu is the prototype of the phoenix is further confirmed by the fact that the former word in Egyptian means also "palm-tree," just as the latter does in Greek. The very various periods named make it probable that the periodical return of the phoenix belongs only to vulgar legend, materializing what the priests knew to be symbolic. Of the birds of the horned family the gorgeous colours and plumed head spoken of by Pliny and others would be least inappropriate to the purple heron (Ardea purpurea), with which, or with the allied Ardea cinerea, it has been identified by Lepsius and Peters (Alteste Texte des Todtenbuchs, 1867, p. 51). But the golden and purple hues described by Herodotus may be the colours of sunrise rather than the actual hues of the purple heron. How Herodotus came to think that the bird was like an eagle is quite unexplained; perhaps this is merely a slip of memory.

Many commentators still understand the word benu, chōl, in Job xxviii. 18 (A.V. "sand") of the phoenix. This interpretation is perhaps as old as the (original) Septuagint, and is current with the later Jews. Among the Arabs the story of the phoenix was confused with the heron. "Ardea cinerea," and other similar species of birds (see Prov. ii. 36 seq.) is represented sometimes as a quadruped, sometimes as a bird. It was firmly believed in, for the incombustible cloths woven of flexible asbestos were popularly thought to be made of its bird or plumage, and were themselves called by the same name (cf. Yaqut i. 529, and Dozy, s.v.). The anāk (Pers. simurgh), a stupendous bird like the roc (rubh) of Marco Polo and the Arabian Nights, also borrows some features of the phoenix. According to Kaempfer (p. 400) it lives 100 years, and when a young bird is hatched the parent of opposite sex burns itself alive. In the book of Kalila and Dimne the simur or anāk is the king of the birds, the Indian garuda, on whom Vishnu rides.

PHOENIX, the capital of Arizona, U.S.A., and the county-seat of Maricopa county, situated on the Salt river, in the south-central part of the state. Pop. (1890), 3,152; (1900), 5,544 (933 being foreign-born and 148 negroes); (1910) 11,134. It is served by the Arizona Eastern and the Santa Fé, Prescott & Phoenix railways, the former connecting at Maricopa (35 m. distant) with the Southern Pacific and the latter connecting at Ash Fork, near Prescott (104 m. distant), with the Atchison, Topeka & Santa Fé. The city is a popular winter and health resort, with a fine dry climate. The city is the see of a Protestant Episcopal bishopric. About 3 m. north of the city is the Phoenix (non-reservation) boarding-school for Indians, supported by the United States government, with an average yearly attendance of 500. The city is the center of the state, and the point of junction of 60. Their names are Phoenix, Gardena (Kemion), Hull, Sydney, Birnie, Enderbury, Canton (Mary) and McKean. To the north-west of the group (between the equator and 1° N.) lie two more islets—Baker and Howland. The islands were annexed by Great Britain in 1859.

PHOENIX ISLANDS, a group of eight small islands in the Pacific Ocean, about 3° S. and 172° W., belonging to Great Britain. They are the northernmost points of the group, the north point of which is 3 mus. and 115 f. (a nautical mile) from the equator. 60 of them are Phoenix, Gardine (Kemion), Hull, Sydney, Birnie, Enderby, Canton (Mary) and McKean. To the north-west of the group (between the equator and 1° N.) lie two more islets—Baker and Howland. The islands were annexed by Great Britain in 1859.

PHOENIXVILLE, a borough of Chester county, Pennsylvania, U.S.A., on the Schuylkill river at the mouth of French Creek, about 28 m. north-west of Philadelphia. Pop. (1800), 851; (1900), 9196, of whom 2221 were foreign-born and 278 were negroes; (1910 census), 16,743. It is served by the Pennsylvania (Schuylkill division) and the Philadelphia & Reading railways, and by the Lehigh Valley line to Spring City (pop. in 1910, 2880). 5 m. north-west of Phoenixville on the Schuylkill. Phoenixville is chiefly a manufacturing borough. Its blast-furnaces and iron mills were long among the largest in the country, and the manufacture of steel is still the borough's predominant industry. Phoenixville was settled in 1732, and was incorporated in 1849.

PHONETICS (Gr. φωνή, voice), the science of speech-sounds and the art of pronunciation. In its widest sense it is the "science of voice," dealing not only with articulate, but also with the inarticulate sounds of animals as well as men. The originally synonymous term, "phonology," is now restricted to the history and theory of sound-changes. The most obvious of the practical applications of phonetics is to the acquisition of a correct pronunciation of foreign languages. But its applications to the study of the native language are not less important: it is only by the help of phonetics that it is possible to deal effectively with vulgarisms and provincialisms of pronunciation and secure uniformity of speech; and it is only on a phonetic basis that the deaf and dumb can be taught articulate speech.

From a more theoretical point of view phonetics is, in the first place, the science of linguistic observation. Without phonetic training the dialectologist, and the missionary who is confronted with a hitherto unwritten language, can neither observe fully nor record accurately the phenomena with which they have to deal. These investigations have greatly widened the scope of the science of language. The modern phoneticist no longer despises colloquial and illogical forms of speech. On the contrary, he considers that in them the life and growth of language is seen more clearly than in dead literary languages, on whose study the science of comparative philology was at first exclusively built up. It was not till philologists began to ask what were the real facts underlying the comparisons of the written words in Sanskrit, Greek, Latin, and the other Indo-European languages, embodied in such generalizations as Grimm's Law, that "letter-science" developed into "sound-science" (phonology). The rise and decay of inflexions, and the development of grammatical forms generally, are, from the formal point of view, mainly phonetic problems; and phonetics enters more or less into every department of grammar.

Methods of Study and Investigation.—Phonetics is the science of speech-sounds. But sounds may be considered from two opposite points of view—the organic and the acoustic. From the organic point of view a sound is the result of certain actions and positions of the organs of speech, as when we define f as a lip-teeth (dento-labial) consonant. This is the point of view of the speaker of a language. To the hearer, on the other hand, f is not a lip-teeth, but a hiss consonant similar to that denoted by /s/. This is the acoustic point of view. Theoretically, the organic study of phonetics is a branch of anatomy and physiology; that part of these sciences which deals with the organs of speech (see MOUTH) and their functions (see VOICE); while, from the opposite point of view, the study of phonetics is based on that branch of physical science known as acoustics (see SOUND), together with the anatomy and physiology of the organs of Hearing (q.v.).

Unfortunately, this basis is still imperfect. The principles of acoustics are well established, and we know much about the anatomy of the ear. But how the ear transmits to the brain the impression of sound is still a mystery. Again, although the mechanism of the vowel is clear enough, there is still no generally received acoustic theory of its formation. In fact, from the physical science point of view there is as yet no science of phonetics.

The real function of phonetics is philological and literary. The only sound basis of a theoretical knowledge of phonetics is the practical mastery of a limited number of sounds—that is to say, of the sounds which are already familiar to the learner in his own language. It is evident that the more familiar a sound is, the easier it is to gain insight into its mechanism and to recognize it when heard. It is indispensable to cultivate both the organic and the acoustic sense. These processes we are continually carrying out in ordinary conversation. All, therefore, that we have to do in dealing with native sounds is to develop this unconscious organic and acoustic sense into a conscious and analytic one. The first step is to learn to isolate each sound: to
PHONETICS

pronounce it, as far as possible, apart from its context; and to preserve it unchanged through every variation of length and force, and in every combination of sounds. The next step is to analyse its formation. Let the student, for instance, compare the tongue positions in a certain sound, such as a /d/ and a /t/, by isolating and lengthening them till he can both hear and feel the variation in the second one. In the same way let him learn to feel the changes in the position of the tongue and lips in passing from one vowel to another. When the native sounds have been thoroughly studied in this way, the learner will proceed to foreign sounds, deducing each new sound from those which are already familiar to him.

The natural method of learning sounds is mainly a subjective one. We listen patiently till our ears are, as it were, in the so-called "Rontgen's class" no. The teacher repetition is mere hit or miss. We hit the position of the organs of speech by which we can reproduce the sound to the speaker's satisfaction. But the natural method also incorporates active improvement and criticism of the movements of the lips and jaws by direct observation. The movements and positions of the tongue and soft palate, and other modifications of the mouth and throat passages are also more or less accessible to observation—
in the case of self-observation with the help of a small mirror held in the hand, the mirror is small enough to go into the mouth, and is fixed obliquely to a handle, so that it can be held against the back of the mouth at such an angle as to reflect a ray of light down the throat, and so have the laryngoscope. Laryngoscopy has confirmed earlier reports, and has added to our knowledge of the throat's state. But, on the other hand, it has been a fruitful source of error. There has been great discrepancy between the results obtained by different observers. Many results which were at first received with implicit confidence for their most rigorous scientific and objective character have been found to be worthless. It seemed at first as if Röntgen's discovery of the so-called X-rays would meet the want of a means of direct observation of the positions of the tongue, not lengthways, but from the side, as also of the interior of the throat. But although the cheeks are to a certain extent transparent to these rays, the shadow of the tongue projected by these means is too indistinct to be of much use.

But there are other methods besides those of direct observation by which the positions of the tongue may be objectively determined and measured with more or less accuracy. The interior of the mouth is examined by the laryngoscope. If the little finger is held against the gums during the articulation of the vowels in it, aé, at, the difference in the height of the tongue will at once become apparent: in the formation of the first vowel the tongue is pressed strongly against the artificial palate, while in that of the second it only just touches it, and in that of the third it does not touch at all.

Several forms of apparatus have been devised for a more accurate determination of the positions of the tongue and the other movable organs of speech. The best results hitherto as regards the vowel-positions have been obtained by Grandgent, who used discs of cardboard fixed to the forefinger. A full description of this and other methods will be found in Scripture's "Elements of Experimental Phonetics."

There are other methods whose results are obtained only indirectly, as well as those of the "phonographers." "Phonographers," as Verner has called them, are obtained "palatograms" recording the contact of the tongue with the palate. The apparatus most generally used consists of a thin, shell-like artificial palate, which is covered with chalk placed in the mouth; when the sound is made, the articulation of the tongue is inferred from the contact-marks on the plate. This method is evidently limited in its application. It, too, has the drawback of not being applicable to the sounds formed in the back of the mouth. The outlines of the contact-marks are more indistinct than they appear in the published drawings of them; and it is a question whether the thickness even of the thinnest plate does not make some record.

The methods hitherto considered are all comparatively simple. They require no special knowledge or training, and are accessible to all. But there are more elaborate methods—many of which, especially those involving special training in practical and theoretical physics and mathematics, and requiring the help of often complicated and costly, and not easily accessible, apparatus. The investigator of the spectroscope, for example, can detect the various stages of sound productions and record them. In this way, for instance, the nature of a phonetic sound can be observed; and even the whole course of its production can be recorded. But this method has been superseded by the Roman numerals. This assumption has had disastrous results. It cannot be too often repeated that instrument phonetics is, strictly speaking, not phonetics at all. It is of no help; it only supplies material which is useless till they have been tested and accepted by the linguistic phonetician's point of view. Sound-Notation; Spelling Reform.—Next to the analysis of the speaking, the most important problem of phonetics is their representation by means of written and printed symbols. The traditional or "nomic" orthographies of most languages are only imperfectly phonetic. And, unfortunately, of the languages in most general use, two are exceptionally unphonetic in their orthographies, French showing the greatest divergence between sound and symbol, while English shows the maximum of irregularity and arbitrariness. The German orthography is comparatively phonetic: it has hardly any silent letters, and it generally has one symbol for each sound, each symbol having only one value, the exceptions falling under a few simple rules, which are easily remembered. There are other languages which have still more phonetic orthographies, such as Spanish, Welsh and Finnish. But even the best of them are not perfect: even when they are not actually misleading, they are always inadequate. On the other hand, no system of writing is wholly unphonetic. Even in French and English there are many words whose spelling is not the most radical reformer would attempt to alter. In fact, all writing which has once emerged from the hieroglyphic stage is at first purely phonetic, as far as its defective means will allow. The divergence between sound and symbol which makes spelling unphonetic is the result of the retention of phonetic spellings after they have become unphonetic through changes in the pronunciation of the words themselves. Thus, such English spelling as knight and wright were still phonetic in the time of Chaucer; for at that time the initial consonants of these words were still pronounced, and the /g/ still had the sound of ch in German ich. So also see and sea are written differently, not by way of arbitrary distinction, but because they were pronounced differently till within the last few centuries—as they still are in Irish-English.

Where there is no traditional orthography, as when Old English (Anglo-Saxon) was first written down in Latin letters, spelling was necessarily phonetic; but where there is a large literature and a class of professional scribes, the influence of the traditional orthography becomes stronger, till at last the invention of printing and the diffusion of one standard dialect over a large area occupied originally by a variety of other dialects make changes of spelling as inconvenient as they were once easy and natural. The ideal orthography for printers is one which is absolutely uniform over the whole territory of the language, and absolutely unchangeable. In such orthographies as those of the present English and French there is no longer any living correspondence between sound and symbol: they are, in intention at least, wholly unphonetic; they are preserved by graphic, not by oral, tradition.

But unphoneticness has its practical limits. A purely unphonetic degradation of an originally phonetic system of writing—one in which there is absolutely no correspondence between sounds and letters—could not be mastered even by the most retentive memory: it would be even more difficult than the Chinese writing. Hence a phonetic reaction is inevitable. In the middle ages the spelling was periodically readjusted in accordance with the changes of pronunciation; as far as possible, as the imperfectations of the existing orthography would allow. This adjustment went on even after the introduction of printing. In fact, it is only within the last hundred years or so that the orthographies of English and French have become fixed.

One result of this fixity is that any attempt to continue the process of adjustment assumes a revolutionary character. When, in 1849, the pioneers of the modern spelling-reform
movement—A. J. Ellis and I. Pitman—brought out the Fonetic Næ, few of those who joined in the chorus of ridicule excited by the new alphabet stopped to consider that this unconveniences was purely the result of habit, and that the Authorized Version of the Bible in the spelling of its first edition would seem to us not less strange and uncouth than in the new-fangled phonoty of Messers Ellis and Pitman. It is easy to consider that phonetics and phonetic spelling, so far from being innovations, are as old as civilization itself. The Alexandrian grammarians were not only phoneticians—they were spelling-reformers; they invented the Greek accents for the purpose of making the pronunciation of Greek easier to foreigners. The Romans, too, were phoneticians: they learnt Greek by phonetic methods, and paid great attention to niceties of pronunciation. The Sanskrit grammarians were still better phoneticians.

As a matter of fact, English spelling was still phonetic as late as the time of Shakespeare—in intention, at least. But although people still tried to write as they spoke, the inherited imperfections of their orthography made it more and more difficult for them to do so. Hence already in the 16th century a number of spelling-reformers made their appearance, including classical scholars such as Sir John Cheke, and A. Gill, who was head-master of St Paul's School in London. Gill has left us extracts from Spenser's Faerie Queene in phonetic spelling; but, strange to say, nothing of Shakespeare's, although he and Shakespeare were exact contemporaries. But Gill's and the other alphabetists proposed were too intricate and cumbrous for popular use.

Nevertheless, some important phonetic reforms were successfully carried through, such as getting rid of most of the superfluous final e's, utilizing the originally superfluous distinctions in form between i and j, u and v, by using u only as vowels, j, v only as consonants, instead of at random—a reform which seems to have begun in Italy. Another important reform was the introduction of oo and oo, as in sea and boat, which had hitherto been written with ee and oo, being thus confused with see and boat. All these were as much phonetic reforms as it would be to utilize long s and tailed z (§ 3.) to denote the final consonants in fish and rouge respectively; a reform first suggested by A. J. Ellis, who was himself the first to call attention to the works of these early phoneticians and to utilize them in the investigations enshrined in his great work on Early English Pronunciation.

With all its defects, the present English spelling is still mainly phonetic, and if we are to attempt to rejuvenate the pronunciation of the vast majority of words from their spelling, we must be prepared to make the best of a bad phonetic spelling, that is, an efficient and easy one. But the difficulties are great; and the more we know of phonetics, and the more we experiment with different systems of spelling, the more formidable do they appear. One of the difficulties, however, that is commonly supposed to stand in the way of spelling-reform is quite imaginary: namely, that it would destroy the historical and etymological value of the present system. Thus E. A. Freeman used to protest against it as "a reckless wiping out of the whole history of the language." Such critics fail to see that historical spelling, if carried out consistently, would destroy the materials on which alone history can be based; that these materials are nothing else but a series of phonetic spellings of different periods of the language, and that if a consistent historical and etymological spelling could have been kept up from the beginning, there would have been no Grimm's Law, no etymology; in short, no comparative or historical philology possible.

The advantages of beginning a foreign language in a phonetic notation are many and obvious. In the first place, the learner who was once mastered the notation and learnt to pronounce the sounds the letters and rules for, is able to look at any word that is presented to him without doubt or hesitation, and without having to burden his memory with rules of pronunciation and spelling. Another advantage of phonetic spelling is that when the learner sees the words written in a representation of their actual spoken form he is able to recognize them at once when he hears them. And if the learner begins with the phonetic notation, and uses it exclusively till he has thoroughly mastered the spoken language, he will then be able to learn the ordinary spelling without fear of confusion, and quicker than he would otherwise have done.

Phonetic spelling-reform may be carried out with various degrees of thoroughness. After the failure of many schemes of radical reform, an attempt was made to begin with those numerous spellings which are both unphonetic and unhistorical, or are against the analogy of other traditional spellings. Accordingly, in 1881 the Philologische Society of London "approved (sic) of certain partial correcions (sic) of English spellings," which were also approved of by the American Spelling-reform Association; and a list of them was issued jointly by the two bodies, and recommended for general adoption. A similar movement has been started in France. But the general feeling appears to be that it is better to keep the ordinary spelling unchanged, and wait till it is possible to supersede it by one on a more or less independent basis.

If the existing Roman alphabet is made the basis of the new phonetic notation of any one language, the most obvious course is to select one of the various traditional representations of each sound, and use that one symbol exclusively, omitting, of course, at the same time all silent letters. A. J. Ellis's English Glossic is an example of such a phonetic spelling on a national basis. The following is a specimen:

Englisch Glossik iz veri ezci too reed. With proper training a child forty-yeer old kan be redlii taut too read Glossik books.

But a system which, like this, writes short and long vowels with totally different symbols (i, ee) is only half phonetic: it is phonetic on an unphonetic basis.

A fully phonetic system, in which, for instance, long vowels and diphthongs are expressed by consistent modifications or combinations of the symbols of the short vowels, and in which simple sounds are, as far as is reasonable and convenient, expressed by single letters instead of digraphs such as sh, must necessarily discard any national basis. The best basis on the whole is obtained by giving the letters their original common European sounds, i.e. by returning to the Late Latin pronunciation, with such modifications and additions as may be advisable. Thus when the vowel is at least half of the Latin basis, its pronunciation is well preserved in German and Italian. In French, on the other hand, the Latin tradition was greatly corrupted already in the earliest period through the rapid changes which the language underwent. Thus when the Latin u in luna assumed the sound it now has in French lune, the symbol was still kept; and when the sound a Afterwards developed again out of the diphthong au, this diphthong was used to denote the sound. So when the French system of spelling came into use in England after the Norman Conquest these unphonetic symbols were introduced into English spelling, so that such a word as Old English and Early Middle English fæs, "house," was written hus in the Middle Late English of Chaucer, although the sound was still that of Scotch hous, on (ow) being also used to denote a true diphthong (ou) in such words as kwon, know, from Old English cadawan.

By returning, then, to the original values of the letters we get the "Romic" or international (Continental) basis as opposed to the Glossic or national basis. Thus the passage quoted above appears as follows in Sweet's "Broad Romic" notation:

"iŋglif gliosikiz iveri izii tu riid. wiis prope treiniŋ a tifuld fo jiiau ould kan biir redlii taut to riid gliosik buks."

Another important general distinction is that between "broad" and "narrow" systems of notation. A broad notation is one which makes only the practically necessary distinctions in each language, and makes them in the simplest manner possible, omitting all that is superfluous. From a practical point of view the necessary distinctions are those on which differences of meaning depend. A phonetic notation of sounds which is significant in one language may be insignificant in another. Thus the distinction between close æ and open ë, ë is significant in French, as in pêcher, pêcher; so if in French phonetic-writing the former
PHONETICS

is denoted by (e), it is necessary to find a new symbol (e) for the open sound. But in languages such as English and German, where the short e is always open, there is no objection to using the unmodified (e) to denote the open sound, even if we regard (e) as the proper symbol of the close sound. And in those languages in which the short e is always open and the long e always close it is enough to mark the distinction of quantity, and leave the distinction of quality to be inferred from it (e, ee).

In such a case as this it is, of course, possible to apply the principle of ignoring superfusional distinctions in the opposite way: by writing the long and short vowels in such a language (e, e), leaving the quantity to be inferred from the quality. But the former method is the more convenient, as it does not require any change of the "broad e" principle is especially convenient in writing diphthongs. Thus in English Broad Romic we write the diphthongs in high and low with the same vowel as ask (hai, hau, ask). Although all these (a) represent different sounds in ordinary southern English pronunciation. But the pronunciation of these diphthongs varies so much in different parts of the English-speaking territory, and the distinctions are so minute that it would be inconvenient to express them in writing; and as these distinctions are non-significant, it would be useless to do so. (a) and (au) are symbols, not of special diphthongs, but of two classes of diphthongs: they can stand for any diphthongs which begin with a vowel resembling the Italian a, and end with approximations to i and u respectively. Theoretically it would be just as correct in English and German to write these diphthongs (ae, ao). But these notations are misleading, because they suggest simple sounds.

In comparing the sounds of a variety of languages, or of dialects of a language, and still more in dealing with sounds in general, we require a "narrow," that is a minutely accurate, notation covering the whole field of possible sounds. It is evident from what has been said above that such a universal scientific alphabet is not suited for practical work in any one language. But the symbols of such a notation as Sweet's "Narrow Romic" are of the greatest use as keys to the exact pronunciation of the vowel sounds of the Broad Romic notations of each language.

To prevent confusion between these two systems of notations Broad Romic symbols are enclosed in ( ), Narrow Romic in [ ], which at the same time serve to distinguish between phonetic and nomic spellings. This in English i ([i]) = [i] means that the English vowel in funny is the "wide" sound, not the "narrow" one in French fini, although in the Broad Romic notations of both languages (fini) is written for funny and fini alike.

Narrow Romic was originally based on A. J. Ellis's "Palaeotype," in which, as the name implies, no new letters are employed. The symbols of Palaeotype are made up, as far as possible, of the letters generally accessible in printing-offices, the ordinary Roman lower-case letters being supplemented by italics and small capitals (i, i, x) and turned letters (a, k), many digraphs (th, sh) being also used. This notation was a reaction from Ellis's earlier phonotopy, in which a large number of new letters were used. Some of these, however, such as s (sh), S = (zh), were afterwards adopted into Broad and Narrow Romic. In his Palaeotype Ellis also discarded diacritical letters, which, as he rightly says, are from a typographical point of view equivalent to new letters. In Narrow Romic a certain number of diacritical letters are used, such as (fi, li), most of which are already accessible. Palaeotype is a Roman-value notation, the main difference as regards the values of the symbols between it and the later systems being that it is more complex and arbitrary. Ellis afterwards had the unhappy idea of constructing a "Universal Glossic" on an English-values basis, which is even more cumbersome and difficult to remember than Palaeotype.

Sweet's Romic systems were made the basis of the "International" alphabet used in Le Maitre Phonétique, which is the organ of the International Phonetic Association, directed by P. Passy. Although this system is at the present time more widely known and used than any other, and although it is constructed on the international Romic principle, it is not really an international system. It is rather an attempt to make a special adaptation of the Romic basis to the needs of the French language into a general notation for all languages. But the phonetic structure of French is so abnormal, so different from that of other languages, that the attempt to force a Broad Romic French notation on such a language as English is even more hopeless than it would be to reverse the process. Although well suited for French, this alphabet must from a wider point of view be regarded as a failure: it is too minute and rigid for practical, and yet not precise enough for scientific purposes. In short, although it has done excellent service, and has helped to clear the way for a notation which shall command general acceptance, it cannot be regarded as a final solution of the problem.

Of the numerous other notations now in use, some still adhere to the diacritic principle of Lepsius's Standard Alphabet (1855), intended for missionary use, but found quite unfit for that purpose because of the enormous number of new types required. Most of them prefer to use new letters formed by more or less consistent modifications of the existing italic letters. A. J. Lundell's Swedish dialect alphabet and O. Jespersen's Danish dialect alphabet are good specimens of this tendency. In the latter Roman letters are used for special distinctions, just as italic letters are used in the Romic systems.

But in spite of all diversity, there is much agreement. As regards the vowels, the following approximate values are now pretty generally accepted:

<table>
<thead>
<tr>
<th>Vowel</th>
<th>English</th>
<th>French</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>[a]</td>
<td>[ɛ]</td>
</tr>
<tr>
<td>ai</td>

</tbody>
</table>

Vowel-length is in some systems denoted by doubling (aa), in others by special marks (a: &c.), the diacritic a being used only in the nomic orthographies of dead and oriental languages. The only consonant-symbols that require special notice are the following:

<table>

All the systems of phonetic notation hitherto considered are based on the Roman alphabet. But although the Roman alphabet has many advantages from a practical point of view, it is absolutely impossible to build up a consistent and systematic notation on such an inadequate foundation of arbitrary signs. What is wanted, for scientific purposes especially, is a notation independent of the Roman alphabet, built up systematically—an alphabet in which there is a definite relation between sound and symbol.

This relation may be regarded either from the organic or the acoustic point of view. The tendency of the earlier attempts at an a priori universal alphabet was to symbolize the consonants organically, the vowels acoustically, as in E. Brücke's Phonetische Transcription (1866). It is now generally acknowledged that the vowels as well as the consonants must be represented on a strictly organic basis. This was first done in A. M. Bell's Visible Speech (1867), which appeared again (1882) in a shorter form and with some modifications under the title of Sounds and their Relations. Bell's pupil, H. Sweet, gave a detailed criticism of Visible Speech in a paper on Sound-notation (Trans. of Philological Society, 1880-1881), in which he described a revised form of it called the Organic Alphabet, which he afterwards employed in his Primer of Phonetics and other works. Sweet's Narrow Romic notation already mentioned is practically a transcription of the Organic Alphabet into Roman letters.

Such notations are alphabetic: they go on the general principle of providing separate symbols for each simple sound. But as
the number of possible shades of sounds is almost infinite, even the most minutely accurate of them can do so only within certain limits. In phonetics, the symbols denoting a class of "modifiers"—characters which are added to the other symbols to indicate nasal, palatal, &c., modifications of the sounds represented by the latter, these modifiers being generally represented by italic letters in the Narrow Romic transcription; thus (l) = nasaled (l).

In the Roman alphabet such symbols as f, v are arbitrary, showing no connection in form either with one another or with the organic actions by which they are formed; but in the Organic symbol of v, for instance, we can see the graphic representation of its components "lips, teeth, voice-murmur."

By omitting superfluous marks and utilizing various typographical devices in the symbols themselves, the simplicity and accuracy of their minute accuracy, are often simpler than in the corresponding Roman notation. The simplicity of the system is shown by the fact that it requires only about 110 types, as compared with the 280 of Lepsius's very imperfect Standard Alphabet.

All the systems hitherto considered are also alphabetic in a wider sense: they are intended for continuous writing, the more cumbrous "narrow" notations being, however, generally employed only in writing single words or short groups. An "alphabetic" basis was first definitely advocated by Jespersen, who represents each sound by a group of symbols resembling a chemical formula, each symbol representing not a sound, but an element of a sound: the part of the palate, tongue, &c., where the sound is formed, the degree of separation (openness) of the organs of speech, and so on. The two great advantages of such a system are that it allows perfect freedom in selecting and combining the elements and that it can be built up on the foundation of a small number of generally accessible signs.

As regards Jespersen's scheme, it is to be regretted that he has not worked it out in a more practical manner: that in his choice of the thirty odd symbols that he requires he should have gone out of his way to mix up Greek with Roman letters, together with other characters which would be avoided by any one constructing even a scientific alphabetic notation. And his use of these symbols is open to much criticism. In fact, it cannot be said that the alphabetic principle has yet had a fair trial.

The Organs of Speech.—Most speech-sounds are formed with air expelled from the lungs (voice-bellows), which passes through the two contractible bronchi or bronchial tubes into the also contractible wind-pipe or trachea, on the top of which is fixed the larynx (voice-box). Across the interior of the larynx are stretched two elastic ledges or cushions called "the vocal chords." They are inserted in front of the larynx at one end, and at the other they are fixed to two movable cartilaginous bodies "the arytenoids," so that the passage between them—the glottis—can be narrowed or closed at pleasure. The glottis is, as we see, twofold, consisting of the chord glottis and the cartilage glottis. The two can be narrowed or closed independently. The chords can also be tightened or relaxed, lengthened and shortened in various degrees.

When the whole glottis is wide open, no sound is produced by the outgoing breath except that caused by the friction of the air. Sounds in whose formation the glottis is in this passive state are called "breath" sounds. Thus (l) is the breath consonant corresponding to the "voice" or "voiced" consonant (v). In the production of voice, the chords are brought close enough together to be set in vibration by the air passing between them. In the "thick" register of the voice (chest voice) the chords vibrate at their whole length, in the "thin" register or falsetto only in part of their length. If the glottis is narrowed without vibration, "whisper" is the result. In the "weak whisper" there is narrowing the whole glottis; in the "strong whisper," which is the ordinary form, the chord glottis is entirely closed, so that the breath passes only through the cartilage glottis. In what is popularly called "whisper"—that is, speaking without voice—the breath sounds remain unchanged, while voiced sounds substitute whisper (in the phonetic sense) for voice. Thus in whispering such a word as feel...
Consonants are generally the result of audible friction, as in (f), or of complete stoppage, as in (p). If the glottis is at the same time left open, as in (f, p), the consonant is "breath" or "voiceless"—if it is narrowed enough to make the chords vibrate, as in (v, b), the consonant is "voice" or "voiced"; intermediate positions producing the corresponding "whispered" consonants. Vowels are characterized negatively by the absence of audible friction or stoppage: if an (i) is formed with the tongue so close to the palate as to cause buzzing, it becomes a variety of the front consonant (j). There is, of course, no difficulty in forming a vowel with the glottis in the position for breath and whisper. Thus breath (i) may often be heard in French in such words as ainsí at the end of a sentence, the result being practically a weak form of the front-breadth consonant (g). The division between vowel and consonant is not an absolutely definite one. As we see, the closer a vowel is—that is, the narrower its configurative passage is—the more like it is to a consonant, and the more natural it is to devocalize it. Some voice consonants, on the other hand, have so little buzz that acoustically they constitute a class between consonants and vowels—a class of "vowel-like" or "liquid" consonants, such as n, m, l.

The changes in sounds which result from active narrowing of the passages admit of an important distinction as "sound-modifying," and "sound-colouring," although the distinction is not always definite. Nasality and rounding are examples of sound-modifying processes. Thus we hear a certain resemblance between (b) and (m), (i) and (y), but we regard these four as distinct and practically independent sounds. Contraction of the pharynx, on the other hand, as also of the false glottis and windpipe, have only a sound-colouring effect: if a vowel is formed with such contractions its quality (timbre) is altered, but it still remains the same vowel. It follows from the definition of speech-sounds that they admit of a twofold classification: (1) organic and (2) acoustic. As already remarked, the older phoneticians used to classify the consonants organically, the vowels mainly from the acoustic point of view. The first to give an adequate organic classification of the vowels was the author of Visible Speech. Bell gave at the same time an independent acoustic classification of the consonants as well as the vowels. His acoustic classification consists simply in arranging the sounds in the order of their "pitches" (tone-heights). The pitches of the breath consonants are absolutely fixed in each individual pronunciation, while those of spoken vowels can be varied indefinitely within the compass of each voice by tightening the vocal chords in various ways and shortening their vibrating portions: the tighter and shorter the vibrating body, the quicker its vibrations, and the higher the tone. But when a vowel is whispered or breathed nothing is heard, but the resonance of the configuration passages, especially in the mouth, and the pitches of these resonant cavities are as fixed as those of the breath consonants; in other words, a whispered (or breathed) vowel cannot be sung. Although the absolute pitches of voiceless sounds may vary from individual to individual the relations of the pitches are constant: thus in all pronunciations (ç) and (j) are the highest, breath (w) in what and whispered (u) nearly the lowest in pitch among consonants and vowels respectively.

If phoneticians were an ideally perfect science there would be no occasion to discuss whether the acoustic or the organic study of the vowels and the other speech-sounds is the more important: a full description of each sound would necessarily imply (1) an exact determination of its organic formation, (2) an acoustic analysis of the sound itself, both from the objective physical point of view and from the subjective one of the impression received by the ear, and (3) an explanation of how (2) is the necessary result of (1). Even this last question has already been solved to some extent. In fact, the connection between the organic formation and the acoustic effect is often self-evident. It is evident, for instance, that (i) and (ç) owe their clear sound and high pitch to their being formed by short, narrow passages in the front of the mouth, while (u) owes its low pitch to being formed in exactly the opposite way, the sound being farther muffled and the pitch consequently still more lowered by the rounding.

One reason why it is impossible to classify the vowels exclusively on acoustic principles is that two vowels formed in quite different ways may have the same pitch. Thus the "high-front-round" (y) and the "high-mixed" (l) have the same pitch, the tongue-retraction of the mixed position of the latter having the same effect as the rounding of the former. It is evident, therefore, that the fundamental classification of the vowels must, like that of the consonants, be purely organic. And although for practical purposes it is often convenient to use the acoustic point of view, all scientific treatment must keep the two points of view strictly apart, and make a special chapter of the relations between them.

Vowels.—The most obvious distinction between vowels is that which depends on the share of the lips in their articulation. In such non-round vowels as (i) and (a) the lips are passive, or even separated and spread out at their corners, by which the vowels assume a clearer resonance. If, on the other hand, the lips are actively approximated, they become the round vowels (y) and "open" (o) respectively.

Vowels are formed with different degrees of rounding. As a general rule, the narrowness of the lip-passage corresponds to the narrowness of the mouth-passage. Thus, in passing from the vowel of aou to those of na and saw the back of the tongue is progressively raised and rounded, and the rounding is diminished in the same proportion.

But there is also abnormal rounding. Thus, if we pronounce (u) with the lips in the position they have in forming (u), the vowel is called "voiceless-rounded" (p). (o) and (u): the second element of the diphthong (ou) in ge is formed in this way. Conversely, the (u) in put is "under-rounded" in the North of England: the tongue position is kept, but the lips are only brought together a little at the corners, as in (3).

The mouth positions of the vowels are the result of two factors: (i) the height of the tongue—its nearness to the palate—and (2) the degree of its retraction. Bell distinguishes three degrees of height: in his system (u) is "high," the (o) of boy is "mid," and the (3) of saw is "low." He also has three degrees of retraction: in "back" vowels, such as (u), the root of the tongue is drawn to the back of the mouth: in "front" vowels, such as (i), the front of the tongue is raised towards the hard palate, so that the tongue slopes down from front to back. In "front" vowels, such as (i), the front of the tongue is raised towards the hard palate, so that the tongue slopes down from front to back.

Most of these slope-positions yield vowels of a distinct and clear resonance. There is also a class of "flat" vowels, such as (e), in which the tongue is in a more or less neutral position. If the tongue is raised from the low-flat position of (a) in bird to the high position of (u) in aou, we get the (i) of North Welsh gems "man," which, as already observed, is acoustically similar to (y).

The flat vowels were called "mixed" by Bell, in accordance with his view that they are combinations of other vowels. Although this view is now generally abandoned, the term "mixed" is still retained by the English school of phoneticians. In this way Bell mapped out the whole mouth by the following cardinal points:

- high-back
- mid-back
- low-back
- high-mixed
- mid-mixed
- low-mixed
- high-front
- mid-front
- low-front

In this arrangement "high-back," etc., are fixed points like those of latitude and longitude. Thus normal "high" means that the tongue is raised as close to the palate as is possible without causing constriction; the term "low" implies retraction of the same kind.

Intermediate positions are defined as "raised," "lowered," "inner," "outer." The most original and at the same time the most disputed part of Bell's vowel-scheme is his distinction of "primary" and "wide." All vowels fall under one of these categories. Thus, the primary French (i) and the corresponding English wide (u) are both high-front-vowels, and it is obvious that the distinction is a semitone lower in pitch. Bell explained the greater openness of the wide vowels as the result of greater expansion of the pharynx; and he considered the other class to be most nearly that of the contraction of the pharynx. Differences in voice-passages in the formation of primary vowels being expanded only so far as to remove all fricative quality, but alterations in the shape of the pharynx have only a sound-colouring, not a sound-modifying effect. Thus, vowel length depends on the shape of the tongue, and accordingly substituted "narrow" for Bell's "primary." He also showed that the distinction applies to consonants as well as vowels: thus the narrow French (s) in son is a consonantization of the narrow French (s) in sou, while the English (w) preserves the wide quality of the (u) in put.

In forming narrow sounds there is a feeling of tension in that
part of the tongue where the sound is formed, the tongue being clenched or bunched up lengthwise, so as to be more convex than in its relaxed or "wide" condition.

The distinction between narrow and wide can often be ignored in the case of "long" vowels, for it generally depends on quantity; length and narrowness, shortness and wideness going together. When the distinction is marked, wide vowels may be expressed by italics, as in German Bläser, while narrow vowels may be written thus: "short."

"Round" vowels had from the beginning been a source of difficulty to students of Visible Speech. But it was not until 1901 that Sweet showed that they are only mixed as regards their articulation, the vowels, i.e., their proper place, for all the vowels except (Joseph) which is always moved forward, are retracted more than the other point consonants. If the tip of the tongue is turned so far back as to articulate with its lower edge against the arch of the palate, it is farther back than for the vowels, and is said to be "emphatic." (Blade-point) is frequent in the dialects of the south-west of England. The opposite of inversion is "protrusion," in which the tip of the tongue is forced forward against the arch of the palate.

"Blade" consonants are formed by the blade or flattened tip of the tongue against the gums, as in English (s, t), or against the teeth, as in the corresponding French sounds. If these consonants are modified by turning the tongue to a back angle, so as to bring the point more into play, they become the "blade-point" consonants (f, s), as in fish, measure. (f) is acoustically a dull (s). In some languages, such as German, sounds similar to (f) and (s) are formed by retracting the tongue, which lowers the tip of the blade in the same way as retraction does, so that the tongue-articulation is only imperfectly carried out. When the rounding is very marked there is only a slight raising of the front of the tongue, as in some Arabic dialects; these are the "tip" consonants. The "tip" consonants are shifted back, and the rounding diminished in the same proportion, (f) can at last develop into the pure back-open consonant (x), as in German "auch" pronounced avch.

The English point consonants (t, d, n, l) are formed on the gums just behind the teeth, the point of the tongue being flattened, so that they are almost blade consonants.

The "emphatic" consonants of Arabic—are modifications of point and blade consonants, in which the sides of the tongue are spread out, so that the hiss of such a consonant as (k) is formed partly between the sides of the tongue and the gums, which, when pointed, gives a peculiar deep, dull quality to these sounds.

"Lip" consonants, such as (p, m), and "lip-teeth" consonants, such as (v, f), offer no difficulty. The simple lip-open-breath (p) may occur in English, it is the sound produced in blowing out a candle. The corresponding voice sound is frequent in German—especially in Middle German—in such words as quaestus.

If the lip-open consonants are modified by raising the back of the tongue, they become the "lip-back" consonants (wh, w) in English what, we, which may also be regarded as consonantized (u). In some languages the lip articulation is further modified by "back-lip" consonants, as in German ach, the reverse is the case.

This last is one of a large number of "lip-modified" consonants, of which the already-mentioned German ch is a further example. This manner of producing sound is peculiarly susceptible to such modifications. In French and other languages it is formed with the tongue more convex than in English, and consequently with a tendency to front-modification. Front-modification of lip consonants is described by the French as gus (or "goose", tsar = emperor, where the final vowels are silent. Some of the consonants are formed below the mouth. When the glottis is sharply opened or closed on a passage of breath or "glottal" effect is produced similar to that of a stop on a passage in the mouth, such as (k). This "glottal stop" is the sound produced in hiccuping; and is an independent sound in some languages, such as Arabic, where it is called hamza. In German all words beginning with a stressed (accented) vowel have a more or less distinct glottal stop before the vowel.

Of the passages below the glottis, the bronchia and the wind-pipes are the most conspicuous and important. Spasmodic contraction of the bronchial passages is the main factor in producing what is known as the "asthmatic wheeze." This if contraction is regulated and made voluntary it results in the deep hiss of the Arabic bâ. If this sound is voiced, it causes a peculiar intermittent vibration of voice, which is habitual with some speakers, especially in Germany. If this effect is softened by slightly expanding the bronchial passages, an (r)-like sound is produced which is the sound used in Germany. Contraction of the windpipe produces a sound similar to the Arabic bâ, but weaker, which when followed by a vowel has the effect of a strong aspirate. When it occurs in a vowel, it adds a new color to the vowel, for example making vowel murmur, or voew, as in the German en. It is one of the uncommon tricks of speech to pronounce so in this manner, to express emphatic denial.

Non-expiratory Sounds.—All the sounds hitherto described imply out-breathing of air. Many of the sounds of the voice are produced with an increased depth.

PHONETICS
Some consonants are formed without either in- or out-breathing, but solely with the air in the throat or mouth. In forming "suction-stops" or "clicks," the tongue or lip are in the position for a stop, but do not close it. Thus, the " click" or "plosive," so that when the stop is loosened, a smacking sound is produced by the air rushing in to fill the vacuurn. Thus the point-click is the interjection of impatience commonly written "in" in many savages signifying a part of language.

Synthesis.—Besides analyzing each sound separately, phonetics has to deal with the phenomena which accompany synthesis or the combination of sounds. Although a sentence may consist of a single word, and that word of a single vowel, sounds mostly occur only in combination with one another. The ordinary division into sentences and words is logical, not phonetic: we cannot mark off sentences and cut them up into words until we know what they mean and are able to analyse them grammatically. But the logical division into sentences corresponds to some extent with the phonetic division into "breath-groups," marked off by our inability to utter more than a certain number of syllables in succession without pausing to take breath. With-in each of these breath-groups there is no necessary pause between the words, except when we pause for emphasis. The only necessary phonetic divisions within the breath-group are those into syllables, sounds and intervening "glides." But before considering these last it will be necessary to say something about the general factors of synthesis: quantity, stress and intonation.

As regards quantity, it is enough for ordinary purposes to distinguish two classes of consonants: those of long and those of short vowels. In English what are called long vowels keep their full length when stressed and before final voice consonants, as in see, broad; and become half-long before voiceless consonants, as in cause, brought. In English the full length is preserved alike before all classes of consonants. The Romance languages have short final stressed vowels, as in French si. Unstressed vowels tend to become short in most languages. The distinctions of quantity apply to consonants as well as vowels. Thus English tends to lengthen consonants after short stressed vowels, as in man compared with German mann, where the final consonant is quite short. Consonants, like vowels, tend to become short when unstressed. But in some languages, such as French, they are not stressed at all, and stress has no effect on quantity, so that in these languages long vowels and double consonants occur as frequently in unstressed as in stressed syllables. In English we often lengthen final unstressed vowels in exclamations, as in what a pity! Some languages, such as the Romance languages and Russian, tend to level the differences of vowel-quantity most of their vowels are half-long.

Stress is the relative importance with which the breath is expelled from the lungs; while acoustically it produces the effect of loudness, which is dependent on the size of the sound-vibrations: the bigger the waves, the louder the sound, and the greater the stress of which we may distinguish infinite degrees.

If we distinguish only three, they are called weak, medium and strong. The use of stress in different languages shows the same variety as quantity. Some languages, such as French, make considerable stress differences among all the sounds and words. In others, there are less degrees of stress among words and sentences with a more or less even degree of force. English, on the other hand, makes great use of minute distinctions of stress both to distinguish the meanings of words and to mark their relations in sentences.

With stress is closely connected the question of syllable-division. A syllable is a group of sounds containing a "syllabic" or syllable-forming vowel, or that is, a sound whose vowel is long enough to constitute a syllable by itself. The distinction between syllables and nonsyllables depends on sonority, the more sonorous sounds being the voice ones, while of these again, the most open are the most sonorous, the most sonorous of all vowels are the diphthongs, and of these the second is the most sonorous. But these differences are only relative. When a vowel and a consonant come together the sonoroussness of the vowel always overpowers that of the consonant, so that the two together form a syllable. Thus "diphthong," and "syllable" are terms applied to the combination of vowels and consonants. In a sentence in which the word "broad" is stressed, the vowel "oa" is the stressed syllable.

The consonant "b" as in "broad," becomes a "voiced stop" when it is followed by a vowel. The "voiceless stop" is the absence of a sound. The "voiced stop" is the production of a sound, the "voiceless stop" results in no sound. The "voiceless stop" is the absence of a sound. The "voiced stop" is the production of a sound, the "voiceless stop" results in no sound.

Intonation or variation of tone (pitch) depends on the rapidity of the sound-vibrations; the more rapid the vibrations, the higher the pitch. Intonation is heard only in voiced sounds, as being the only ones capable of variations of pitch.

In singing the voice generally dwells on each note without change of pitch, and then leaps up or down to the next note as quickly as possible, so that the intervening "glide" is not noticed—except in what is called portamento. In speaking, on the other hand, the voice hardly ever dwells on any one note, but is constantly gliding from one note to another so that an absolutely level tone hardly ever occurs in speech. But if the right kind of intonation we can distinguish between "voice-glide" (portamentos or slurs) and "voiced-leaps," although the distinction is not so definite as in singing.

Of the three primary forms of intonation the level tone (l) can be approximately heard as in well as an expression of muous—although it really ends with a slight rise; the rising (l) in the question were? the falling (l) in the answer why is? The compound rising tone (l) may be heard in take care! the compound falling tone (l) as in the sarcastic oh! All these tones may be varied according to the purpose to which they are put. The greater the rise, the more emphatic the tone. Thus a high rise, which begins high, and consequently can only rise a little higher, expresses simple question, while the same word, if uttered with a low rise extending over an interval of between a fifth and an octave—or even more—expresses various degrees of surprise or indignation, as in the emphatic what? compared with the simply interrogative what?

In English and in many European languages, intonation serves to modify the general meaning and character of sentences. This is sentence-intonation. But some languages, such as Swedish and Norwegian, and Chinese, have word-intonation, by which words which would otherwise be identical in sound are distinguished. The distinction between Gr. olkoi and elkei was no doubt one of intonation.

Glides.—Such a word as cai consists not only of the vowel and the two consonants of which it is made up, but also of a glide for transitions between these sounds. The glide from the initial consonant to the final vowel consists of a series of intermediate positions through which the tongue passes on its way from the (k)-position to the (ae)-position. The number of these positions is infinite, but they are all implied by the mere juncture-position of the symbols, for it is assumed that in all transitions from one position to another the shortest way is taken. Although the direction of a glide is dependent on the positions of the two fixed points between which it lies, its character may be varied both by the shape of the configurative passages—especially the glottis—and by stress and quantity.

In the word given above the "off-glide" from the consonant and the breath-glides, the glottis being kept open during the transition from the voiceless consonant to the following vowel, or, as in the case of the final consonant, to silence. The "on-glide" from the vowel to the (t) is, on the other hand, a voice-glide, the closure of the glottis being maintained till the stop is made.

In French and most of the languages of the south of Europe voiceless consonants are followed by voice-glides. Thus in French qui there is no escape of breath after the (k), as there is in English Key. Other languages again have breath on-glides before voiceless stops.

If an independent strong stress is put on the breath-glide of English key, it is heard almost as a full independent consonant, and becomes an "aspirate." Aspirated steps may be heard in the Irish-English pronunciation of such words as tell, and also in Danish, and in Sanskrit as pronounced in India. If the voice-glide after a voice stop is emphasized in a similar way the "sonant aspirates" of Sanskrit and its modern descendants are produced, as in Sanskrit dhanu.

Glides are especially important from an acoustic point of view. Acoustically speaking, indeed, voiceless stops are pure glide-sounds, the stop itself being inaudible. In voice-stops, on the other hand, the stop itself can be made audible as well as the intervening glides. In English these latter are fully voiced when they come between voice sounds, as in age; but when preceded by voiceless sounds or by a pause, as in gel they are formed with imperfect vocality, full voice being heard only just before the stop is loosened. So also initial English (z) as in zeal is formed with imperfect vocality under the same conditions, so that it sounds like (sz). In French and other languages which have voice-glides after voiceless consonants initial (g, z) &c. are fully voiced.

Consonant-glide is may be further modified in various ways. In the formation of "implosive" stops, such as occur in Saxon German, Armenian and other languages, voiceless stops followed
by voice-glides are modified by simultaneous closure of the glottis, the larynx being raised by means of its muscles, so that it acts like a plug, compressing the air between the closed glottis and the mouth-stop, so that when the latter is released a peculiar choky effect is given to the off-glide.

Rounded glides may be heard in Russian in such words as komnata, where the rounding of the (o) is anticipated in the preceding consonant, being heard, of course, only in the off-glide of the consonant. The acoustic effect is between that of (kwo) and ordinary (ko).

Glideless consonant-combinations remain to be considered. The general articulatory principle of taking the shortest way between sounds in juxtaposition necessarily results in certain transitions being effected without any glide at all. This is regular if the two consonants have the same place and differ only in form, as in (nd, dl), where the point of the tongue remains unmoved through the whole sound-group. In such combinations as (mf) the very slight glide is often got rid of entirely by assimilating the place of the first consonant to that of the second, so that the (m) becomes a lip teeth consonant, as in English nymph.

Even when consonants are formed in different parts of the mouth it is often possible to join them without any glide. In English such combinations as (kt, pt) are glideless, the point of the tongue being brought into position before the preceding stop is loosened. In French and most other languages such combinations are formed by a glide.

Combinations of stops and vowel-like consonants (tr, gl, kw) are glideless in English and most other languages. In English the breath-glide after a voiceless stop unmoves the beginning of the following vowel-like consonant; thus try is almost (trh-rail).

Vowel-glides.—Vowels are begun and ended in various ways. In the "gradual beginning," which is the usual one in English and French, the vowel is pushed out while breath is being emitted. In the "clear" beginning the breath is kept back till the glottis is closed for voice, which begins without any "breathiness". Complete or smooth air current favours the clear beginning, generally exaggerating it into a glottal stop.

In the gradual as well as the clear beginning the stress begins on the vowel. If in the former it is thrown back on the breath-glide, the latter is felt as an independent element and becomes the "aspirate" or (h), which in English and most other languages is a glide not only in the throat but in the mouth as well, the tongue and lips gradually moving up into the position for the following vowel while the glottis is being closed.

There is also a "strong" aspirate, which occurs in Finnish and other languages, in the formation of which the full vowel position is assumed from the beginning of the aspiration, which is therefore a vowel with a consonant.

In most languages, where an aspirate comes between voice sounds it is formed with imperfect vocality, the contrast of which with the full vocal quality of the preceding sounds being a characteristic of breath. Thus in English behold the voice runs on without any actual break, the glottal closure being simply relaxed, not fully opened for breath, as in the emphatic aha! In some languages, such as Bohemian, this "voice-aspirate" is used everywhere initially as well as mediaily.

Vowels are finished analogously, either by a gradual opening of the glottis, or by a cessation of aspiration while the glottis is still closed for voice. If stop is begun and the glottis ending it becomes a distinct aspirate, as in the Sanskrit "visarga" in such a word as manah.

Organic Basis.—Every language has certain general tendencies which control the formation of its sounds, constituting its "organic basis" or basis of articulation. The tendency of the tongue to flatten and lower the tongue and draw it back from the teeth, while the lips are kept as much as possible in a neutral position. The flattening of the tongue makes our vowels wide and favours the development of mixed vowels, and gives the dull quality which is especially noticeable in our (l); and its retraction is unfavourable to the development of teeth sounds; while the neutrality of the lips eliminates front-round vowels. In such a language as French everything is reversed. The tongue is arched, and raised, and advanced, and the lips articulate with energy. Hence French sounds tend to narrowness, dentality and distinct rounding.

National Sound-systems.—Each language uses only a part of the general phonetic material. Each one has only a limited number of sounds; and each one makes only a limited use of the synthetic distinctions of quantity, stress and intonation. As we have seen, many of these differences between individual languages are the result of, or may be referred to, differences in their organic basis.

Just as cognate languages differ from each other in phonetic structure, so also dialects of the same languages differ from each other more or less. Thus the sound-system of Lowland Scotch—which is, historically, a dialect of Northern English—differs considerably from that of standard English. Standard English itself was originally that mixture of the Midland and the Southern dialect which was spoken in London in the middle ages, just as standard French is, historically, the dialect of that district which was spoken in central France. And, while standard French, is now more a class-dialect than a local dialect, it remains a local dialect of the educated all over Great Britain. But it is not yet perfectly uniform. It is still liable to be influenced by the local dialects in grammar and vocabulary, and still more in pronunciation.

Again, English, like all other living languages, changes from generation to generation. Pronunciations which are vulgar in one century may become fashionable in the next. Sounds which are distinct in one generation may be confounded in another, and new distinctions may be made, new sounds may arise. A spoken language is, therefore, necessarily a vague and fluctuating entity, and there is no exception to the rule. The very fixity of its written form gives all the freer play to the influences which cause change.

A standard spoken language is, strictly speaking, an abstraction. No two speakers of standard English pronounce exactly alike. And yet they all have something in common in every sound they utter. There are some divergences, some peculiarities of pronunciation, which pass unnoticed, while others, less considerable perhaps in themselves, are at once felt as archaisms, vulgarisms or provincialisms, as the case may be, by the majority of educated speakers.

Sounds of English.—The following is a convenient classification of the vowels of standard English:

<table>
<thead>
<tr>
<th>Vowel</th>
<th>Pronunciation</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>in ten, good</td>
</tr>
<tr>
<td>aa</td>
<td>in can</td>
</tr>
<tr>
<td>a</td>
<td>in the</td>
</tr>
<tr>
<td>ai</td>
<td>in one</td>
</tr>
<tr>
<td>e</td>
<td>in ban</td>
</tr>
<tr>
<td>ee</td>
<td>in man</td>
</tr>
<tr>
<td>i</td>
<td>in in</td>
</tr>
<tr>
<td>o</td>
<td>in noon</td>
</tr>
<tr>
<td>oo</td>
<td>in cow</td>
</tr>
</tbody>
</table>

Here the vowels are in four rows: (1) normally short, or, more correctly, monophthongic, (2) long, or half-diphthongic, (3) full diphthongic, (4) murmured-diphthongic.

In the first (1) row (a) is pronounced in monophthongal sounds such as ten, good, but they always remain absolutely monophthongic. The only one in the next row that is always strictly monophthongic is (oa); all the others, as we shall see, tend to become more or less diphthongic, especially (oo) which, being often exaggerated, is considered as a full diphthong. The (a) and (oa) vowel is a dual, having (a) a more open and (oa) a more closed pronunciation.

In the second (2) row: (a) in come up, is the short vowel corresponding to the (aa) in calm. (aa) is the mid-back-wide vowel, and (a) differs from it only in being narrow. Acoustically, (a) is a muffled or obscure (aa): and the same effect may be produced by advancing the tongue from the mid-back to the corresponding out-back position, preserving the wide articulation: this pronunciation of (a) is common in pronunciations of the south of England. Historically, these sounds are the result of unrounding and older (u),

In the third (3) row: (o), as in sofa, is a mixed vowel, tending to wideness and mid position, as occurs only unstressed. (oo) in turn, earth, is low-mixed-narrow. It is the result of absorption of an older (e), weakened into (o).

In the fourth (4) row, (e), as in man, is low-front-wide, from older mid-back-wide. (i) in is high-front-wide. The long (ii) in eat is narrow in the north of England, while in the south it is wide (i) followed by (l).

In the fifth (5) row, (e) in men is generally mid-front-wide, (ei) in mane is the same vowel either narrow or wide, raised in its latter half towards (i).

The most high is generally mid-back-wide. Narrow (un) in too becomes (uw) in southern English.

In the (6) row, (o) in not is low-back-wide-round. In (ou), as in no, the mid-back-round vowel, either narrow or wide, is over-rounded in its latter half. (o), as in all, is low-back-narrow-round.

The full diphthongs (ai, au, oi), as in eye, now, oil, all end in lowered high vowels. Their first elements are only roughly indicated by the transcription, and vary in the mouths of different speakers. That of (ai) is generally the out-mid-back-wide, that of (au) is the broader low-mixed-wide, that of (oi) the mid-back-wide-round.

The murmured-diphthongs (ia) as in here, (ea) as in air, (ua) as in
poor, all tend to broaden their first elements. That of (e) is the low-front-narrow vowel. The other two begin with lowered forms of the wide (a) and (u) respectively. In (a) the lowering is often carried so far as to make poor almost, or completely, into pie (pis).

The bowing arrangement of the English consonants will show their organic relations to one another:

\[
\begin{align*}
\text{j} & \quad \text{p} & \quad \text{s} & \quad \text{z} & \quad \text{f} & \quad \text{v} \\
\text{k} & \quad \text{t} & \quad \text{d} & \quad \text{b} & \quad \text{n} & \quad \text{m}
\end{align*}
\]

The "aspirate" (h) may be regarded either as a throat-consonant or as a breath-glide.

Characteristic features of the English consonant-system are the large number of hisses and buzzes, the sharp distinction of breath and voice, and, negatively, the absence of the open-back consonants, and of the place of articulation the voiceless biblical consonants (l, r) and the nasals, most of which still existed in Old English.

PHONOGRAPH (Г. фонох, sound, γράφω, to write), an instrument for imprinting the vibrations of sound on a moving surface of tinfoil or wax in such a form that the original sounds can be reproduced by means of a suitable mechanism. Many attempts had been made by earlier experimenters to obtain tracings of the vibrations of bodies emitting sound, such as tuning-forks, membranes, and glass or metallic disks. In 1807 Thomas Young ( Lectures, i, 191) described a method of recording the vibrations of a tuning-fork on the surface of a drum; his method was fully carried out by Wilhelm Wettmer in 1842 (Recherches sur l'élasticité, 1re mém.). Recording the vibrations of a membrane was first accomplished by Leon Scott in 1857 by the invention of the "phonotograph," which may be regarded as the precursor of the phonograph (Comptes rendus, 35, p. 108). This instrument consisted of a thin membrane to which a delicate lever was attached. The membrane was stretched over the narrow end of a thin, irregularly-shaped funnel or drum, while the end of the lever, or "pointer," was bent against the surface of a cylinder covered with paper on which soot had been deposited from a flame of turpentine or camphor. The cylinder was fixed on a fine screw moving horizontally when the cylinder was rotated. The marker thus described a spiral line on the blackened surface. When sounds were transmitted to the membrane and the cylinder was rotated the oscillations of the marker were recorded. Thus tracings of vibrations were obtained. This instrument was much improved by Karl Rudolph König, of Paris, who also made it with many valuable observations. (See Nature, Dec. 26, 1901, p. 184). The mechanism of the recording lever or marker was improved by William Henry Bate, in 1874, in an instrument called by him the "logograph" (Proc. Acad. Arts, 1874). The next step was König's invention of manometric flames by which the oscillations of a thin membrane under sound-presures acted on a small reservoir of gas connected with a flame, and the oscillations were viewed in a rotating rectangular mirror, according to a method devised by Charles Wheatstone. Thus flame-pictures of the vibrations of sound were obtained (Pogg. Ann., 1861, cxxii. 242, 660; see also Quelques expériences d'acoustique, Paris, 1884). Clarence Blake in 1876 employed the drum-head of the human ear as a logograph, and thus obtained tracings similar to those made by artificial membranes and disks (Archiv. für Öphäkmol., 1876, v. 1). In the same year Sigmund Theodor Stein photographed the vibrations of tuning-forks, violin strings, &c. (Pogg. Ann., 1876, p. 142). Thus from Thomas Young downwards successful efforts had been made to record graphically on moving surfaces the vibrations of sounds, but the sounds so recorded could not be reproduced. This was accomplished by T. A. Edison in 1876, the first patent being dated January 1877.

In the first phonograph a spiral groove was cut on a brass drum fixed on a horizontal screw, so that when the drum was rotated the right end of the screw was forced to and fro by vibrations of a thin membrane, and the nasals, most of which still existed in Old English.
the wax cylinder is rotating, the point of the marker is angled downwards, and this cuts deeply into the wax; and when there is diminution of pressure the point is angled upwards, so as to act less deeply. In reproducing the sound, the blunt end of the marker runs over all the elevations and depressions in the bottom of the groove cut on the wax cylinder. There is thus increased pressure transmitted upwards to the glass disk when the point runs over an elevation, and less pressure when the point runs over a depression on the wax cylinder. The glass disk is thus, as it were, pulled inwards and thrust outwards with each vibration, but these pulls and thrusts follow each other so rapidly that the ear takes no cognizance of the difference of phase of the vibrations of the glass plate in imprinting and in reproducing. The variations of pressure are communicated to the glass plate, and these, by the medium of the air, are transmitted to the drum-head of the ear, and the sound is reproduced with remarkable fidelity. It is necessary for accurate reproduction that the point of the marker be in the centre of the groove. In the older phonographs this required accurate adjustment by a fine screw, but in newer forms a certain amount of lateral oscillation is allowed for the purpose of focusing the sound-waves upon the diaphragm. The artist and the funnel are on one side of a screen and the recording apparatus in charge of an operator on the other.

The arrangement of the various instruments in the recording room at proper relative distances from the horn is of the utmost importance in order to preserve the balance of tone. At about 4 ft. from the horn are grouped the violins and the wood winds (flutes, oboes and clarinets); behind the brass wind (horns, trumpets, trombones and tubers), and right at the back the violoncellos and double basses and the kettle-drums and other instruments of percussion which may be required. On the other side of the screen is the sound-box and the recording cylinder or disk.

Cylinder records are duplicated by taking a plaster cast, electroplating, and then using it as a matrix. The disk record admits of similar treatment. After dusting with graphite it is electroplated to about 9 mm. thick. This forms the permanent or master record, from which the working negatives are made by taking wax impressions of it and obtaining copper electro-tips in turn from them. The matrix is then nickel-plated and polished and is ready for use in pressing out the commercial records by means of an hydraulic press, the material used being a tough and elastic substance containing shellac and other compounds such as wood charcoal, barium sulphate, earthy colouring matters and cotton flock.

There is still a defect to be overcome in the gramophone, and that is the hissing of the needle produced by friction both during recording and intensified in reproduction. In one device for remedying this the stylus acts like a stylographic pen, depositing on a polished surface a fine stream of some liquid which solidifies and hardens very rapidly, forming a sinusoid ridge instead of a groove. A negative is taken of the record and the matrix is made from it in the usual way.

The auxeto-gramophone or auxotophone, patented by Short in 1898 and improved by the Hon. C. A. Parsons, is similar in scope to the gramophone but attaining its results in a different manner. In the Parsons-Short sound-box there is no diaphragm, but a
column of compressed air is controlled by a delicately adjusted grid-valve consisting of a metal comb rigidly connected to the stylus bar, so that as the needle moves the metal comb moves with it, following the lines of vibration fixed on the record and opening or closing the slots in the valve seat. The column of compressed air to which the valve gives access thus receives series of minute pulsations identical with those which originally produced the sound recorded. In connexion with the sound-box is the apparatus for supplying compressed air, consisting of a sixth-horse power electric motor driving the compressor, an oil filter, a reservoir and a dust collector to keep the air absolutely free from foreign substances likely to interfere with the action of the valve.

The practical possibilities of the gramophone are being realized in many countries. Matrices of the records of well-known artists have been deposited at the British Museum and at the Grand Opera in Paris. Austria established a public phonogram record office in 1903, in which are collected folk-songs and records of all kinds for enriching the department of ethnography. The same idea is being carried out in Germany by private societies and by royal museums. In Hungary records of the various dialects have been secured. The possibilities of the gramophone as a teacher are far-reaching, not only in the domain of music but in learning languages, &c.

To understand how the phonograph records and reproduces musical tones, it is necessary to remember (1) that pitch or frequency depends on the number of vibrations executed by the vibrating body in a given period of time, or on the duration of each vibration; (2) that intensity or loudness depends on the amplitude of the movement of the vibrating body; and (3) that quality, timbre or clang, first, depends on the form of the individual vibrations, or rather on the power the ear possesses of appreciating a simple pendular vibration producing a pure tone, or of decomposing more or less completely a compound vibration into the simple pendular vibrations of which it is composed. If we apply this to the record of the phonograph, we find that, given a constant and sufficiently rapid velocity of the record, a note or tone of a certain pitch will be heard when the marker runs over a number of elevations and depressions corresponding to the frequency of that note. Thus if the note was produced by 200 vibrations per second, and suppose that it lasted in the music for $\frac{1}{8}$ of a second, 20 marks, each made in $\frac{1}{72}$ of a second, would be imprinted on the wax. Consequently, in reproduction, the marker would run over the 20 marks in $\frac{1}{8}$ of a second, and a tone of that frequency would be reproduced.

The loudness would correspond to the depth of each individual mark on the cylinder or the width on the disk. The greater the depth of a series of successive marks produced by a loud tone, the greater, in reproduction, would be the amplitude of the vibrations of the glass disk and the louder would be the tone reproduced. Lastly, the form of the marks corresponding to individual vibrations would determine the quality of the tone or note reproduced, by which we can distinguish the tone of one instrument from another, or the sensation produced by a tone of pure and simple quality, like that from a well-bowed tuning-fork or an open organ pipe, and that given by a trumpet or an orchestra, in which the sounds of many instruments are blended together. When the phonograph records the sound of an orchestra it does not record the tones of each instrument, but it imprints the form of impression corresponding to the very complex sound-wave formed by all the instruments combined. This particular form, infinitely varied, will reproduce backwards, as has been explained, by acting on the glass plate, the particular form of sound-wave corresponding to the sound of the orchestra.

Numerous instruments blend their tones to make one wave-form, and when one instrument predominates, or if a human voice is singing to the accompaniment of the orchestra, another form of sound-wave, or rather a complex series of sound waves, is imprinted. When reproduced, the wave-forms again exist in the air as very complex variations of pressure; these act on the drum-head of the human ear, there is transmission to the brain, and there an analysis of the complex sensation takes place, and we distinguish the trombone from the oboe, or the human voice from the violin obbligato.

Many efforts have been made to obtain graphic recordings of wave-forms imprinted on the wax phonograph records. Thus J. G. M'Kendrick took (1) celluloid casts of the surface, and (2) micro-photographs of a small portion of the cylinder (Journ. of Anat. and Physiol., 1878, July 1878). He also devised a phonograph recorder by which the curves were much amplified (Trans. Roy. Soc. Edin., vol. xxviii.; Proc. Roy. Soc. Edin., 1890—1897, Opening Address; Sound and Speech Waves as revealed by the Phonograph, London, 1897; and Schäfer's Physiol., vol. ii., "Vocal Sounds," p. 1226). As already mentioned, so long ago as 1878 Fleming Jenkin and Ewing had examined the marks on the tin-foil phonograph. Professor Ludimar Hermann, of Königsberg, took up the subject about 1890, and devised the wax-cylinder phonograph. He obtained photographs of the curves on the wax cylinder, a beam of light reflected from a small mirror attached to the vibrating disk of the phonograph being allowed to fall on a sensitised plate while the phonograph was slowly travelling. (For references to Hermann's important papers, see Schäfer's Physiology, ii. 1222.) Boeke, of Alkmaar, has devised an ingenious and accurate method of obtaining curves from the wax cylinder. He measured by means of a microscope the transverse diameter of the impressions on the surface of the cylinder, on different (generally equidistant) parts of the period, and he infers...
from these measurements the depth of the impressions on the same spot, or, in other words, he derives from these measurements the curve of the vibrations of the tone which produced the impression.

**FIG. 4.**

From a communication to the Dutch Otorhinolaryngological Society Dr Boeke has permitted the author to select the accompanying illustrations, which will give the reader a fair conception of the nature of the marks on the wax cylinder produced by various tones. Fig. 2 shows portions of the curves obtained by Hermann, and enlarged by Boeke one and a half times. The numbers 1 to 4 refer to periods of the vowel A (as in "hard "), sung by Hermann on the notes e, e', e'', e'''. Numbers 5 to 8 show the curves of the vowel o (as in "go") sung to the same notes. The number of vibrations is also noted. Boeke measured the marks for the same vowels by his method, from the same cylinder, and constructing the curves, found the relative lengths to be the same. In fig. 3 we see the indentations produced by the same vowels, sung by Hermann on the notes e, e', e''; on the same phonograph cylinder, but delineated by Boeke after his method. The curves are also shown in linear fashion beside each group of indentations. From these measure-

ments the curves were calculated and reproduced, as in fig. 4. Thus the curves of the same vowel sounds on the same cylinder are shown by two methods, that of Hermann and that of Boeke.

**FIG. 5.**

In fig. 5 we see the indentations on the vowel a, sung by Dr Boeke, aged 85, on the notes c, d, e, f, g, a, b, e', and near the frequencies of 128, 144, 160, 170-6, 192, 213-3, 240 and 256. The numbers 33 to 40 show the marks produced by the same vowel, sung by his son, aged 13. It will be seen that the boy sang the notes exactly an octave higher. Fig. 6 shows the marks produced by some musical sounds. Each shows on the right-hand side the curve deduced from the marks, and under it a graphical representation of the results of its harmonic analysis after the theorem of Fourier, in which the ordinates represent the amplitude of the subsequent harmonic constituents. No. 41 is the period of the sound of a pitch-pipe giving a' (425 double vibrations per second), No. 42 the period of a Dutch pitch-pipe, also sounding a' (424-64 double vibrations per second). No. 43 is a record of the period of a sound produced by blowing between two strips of indiarubber to imitate the vocal cords, with a frequency of 453 double vibrations per second. No. 44 is that of a telephone pipe used by Hermann (503 double vibrations per second). Nos. 45 and 46 show the marks of a cornet sounding the notes a at 400 double vibrations per second, and e of 300 double vibrations per second. In fig. 7 are shown a number of vowel curves for the vowels o, o', a, e and i. Each curve has on the right-hand side a graphical representation of its harmonic analysis. The curves are in five vertical columns, having on the
PHONOLITE—PHORMIUM

left-hand side of each drawings, by Boecke's method, for two periods of the marks of the vowel. The marks are also shown for the Dutch, German, French and English languages. The sounds of the vowels are "e", "o", "i", "u", and "a". The first section contains only Dutch vowel sounds, either sung or spoken by Boecke or members of his family. The second section of the phonolites curves from the first vowel to the third from the voice of the author from a cylinder sent by him to Dr Boecke, and the fourth from the voice of Mons. H. Marichelle, professeur de l'Institut des Sourd-Muets, also forwarded by him to Dr Boecke. The third and fourth marks and marks in the same vowel are shown from the voices of men of four nationalities.

On the construction of the gramophone, see L. N. Reddie, Journ. Soc. Arts (1908).

PHONOLITE (Gr. φωνή, sound, and άλβος, stone), in petrology, a group of volcanic lavas containing much nepheline and sanidine felspar. The term "phonolite" was formerly given by geologists to many fine grained compact lavas, which split into thin tough plates, and gave out a ringing sound when struck with the hammer. Some of these clinkstones were phonolites in the modern sense, but as the name clinkstone was used for a large variety of rocks, many of which have no close affinities with one another, it has been discarded and "phonolite" is substituted for it. The group includes rocks which are rich in alkalis with only a moderate percentage of silica; hence they contain no free quartz but much alkali felspar (sanidine and anorthoclase) and nepheline. Large plates of sanidine are often visible in the rocks; the nepheline is usually not obvious to the unaided eye. Most phonolites show fluxion structure, both in the orientation of their phenocrysts and in the smaller crystals which make up the ground-mass; and this determines to a large extent the platy jointing. Although vitreous and pumiceous forms are known they are rare, and in the great majority of cases these rocks are finely crystalline with a dull or shimmering lustre in the ground-mass. Marked characteristics are the readiness with which they decompose, and the frequency of veins and cavities occupied by natrolite, analcite, scoscope and other zeolites. Small black grains of augite or hornblende and sometimes blue specks of haüyne may be seen in the rocks when they are fresh.

The dominant minerals are sanidine, nepheline, pyroxene, amphibole, various felspathoids and iron oxides. The sanidine is usually in two generations, the first consisting of large crystals of flattened and tabular shape, while the second generation is represented by small rectangular prisms arranged in parallel streams in the ground-mass; these felspars are nearly always simply twinned on the Carlsbad plan. They contain often as much soda as potash. The nepheline takes the form of hexagonal prisms with flat ends, and may be completely replaced by fibrous zeolites, so that it can only be recognized by the outlines of its pseudomorphs. In some phonolites it is exceedingly abundant, and magnetite and zircon occur in the phonolites, and sphene is often rather common. Another mineral which is more frequent in phonolites than in many other rocks is brown melanite garnet.

The majority of the rocks of this group are of Tertiary or Recent age, but in Scotland Carboniferous phonolites occur in several localities, e.g. Traprain in Haddingtonshire, also in the Eildon Hills and in Renfrewshire. In Brazil phonolites belonging to the same epoch are also known. There are several districts in Europe where Tertiary or Recent phonolites occur in considerable numbers, as in Auvergne (Mont Dore), the Eifel, and Bohemia. The Wolf Rock which lies off the south coast of Cornwall, and is the site of a well-known lighthouse, is the only mass of phonolite in England; it is supposed to be the remains of a Tertiary lava or intrusion. The Canary Islands, Cape Verde Islands, Sardinia, Aden, British East Africa and New Zealand contain many types of phonolites; they are known also in New South Wales, while in the United States phonolites occur in Colorado (at Cripple Creek) and in the Black Hills of South Dakota.

Leucite occurs in place of nepheline in a small group of phonolites (the leucite-phonolites), known principally from Roccia Monfina and other places near Naples. Blue haüyne is rather a conspicuous mineral in some of these rocks, and they also contain a good deal of sphene. When sanidine, nepheline and leucite all occur together in a volcanic rock it is classed among the leucophyres (see PETROLOGY, Plate III. fig. 2).

The chemical analyses of phonolites given below show that these rocks are very rich in alkalis and alumina with only a moderate amount of silica, while lime, magnesia and iron oxides are present only in small quantity. They have a close resemblance in these respects to the nepheline-syenites of which they provide the effusive types.

PHORCUS (Phorokus, Phorocy), in Greek mythology, son of Pontus (Sea) and Gaea (Earth), father of the Graeae, the Gorgons, Scylla, and Ladon (the dragon that guarded the golden apples of the Hesperides). In Homer (Odyssey, xiii. 96) he is an aged sea-deity, after whom a harbour in Ithaca was named. According to Varro (quoted by Servius in Aeneid, v. 824) Phoros was a king of Corsica and Sardinia, who, having been defeated by King Atlas in a naval engagement in the course of which he was drowned, was subsequently worshipped as a marine divinity.

PHORMIUM, or NEW ZEALAND FLAX (also called "Phormium tenax") (n. ord. Liliaceae), a native of New Zealand, the Chatham Islands and Norfolk Island. This useful plant is one of the many which were discovered by Sir Joseph Banks and Dr Solander who accompanied Captain Cook on his first voyage of discovery. The seeds brought home by Banks in 1771 did not succeed, but the plant was introduced by him to the Royal Gardens at Kew in 1789, and was thence liberally distributed in Great Britain and the continent of Europe. It grows luxuriantly in the south of Ireland, where it was introduced in 1798, and also flourishes on the west coast of Scotland, and is generally cultivated as an ornamental garden plant in Europe. It has been introduced for economic purposes into the Azores and California. The name Phormium is from Gr. φορούμ, a basket, allusion to one of the uses made of its leaves by the New Zealanders. In its native country the plant is generally found near the coast. It has a fleshy rootstock, creeping beneath the surface of the soil and sending up luxuriant tufts of narrow, sword-shaped leaves, from 4 to 8 ft. long and from 2 to 4 in. in diameter. The leaves are vertical, and arranged in two rows as in the garden flag; they are very thick, stiff and leathery, dark green above, paler below, with the margin and nerve reddish-orange. From the centre of the tuft ultimately arises a tall flower-bearing stem, 5 to 15 ft. high, bearing on its numerous

PHORONIDEA

branches a very large number of lurid red or yellow, somewhat tubular flowers, recalling those of an aloe, and from 1 to 2 in. long. After flowering the plant dies down, but increases by new lateral growths from the rootstock. The plant will grow in almost any soil, but best on light rich soil, by the side of rivers and brooks, where sheltered from the wind.

Phoroniurn has been treated as a cultivated plant in New Zealand, though only to a limited extent; for the supplies of the raw material dependence has been principally placed on the abundance of the wild stocks and on sets planted as hedges and boundaries by the Maoris. Among these people the fibre has always been an article of considerable importance, yielding cloaks, mats, cordage, fishing-lines, &c., its valuable properties having attracted the attention of traders even before colonists settled in the islands. The leaves, for fibre-yielding purposes, come to maturity in about six months, and the habit of the Maoris is to cut them down twice a year, rejecting the outer and leaving the central immature leaves. Fandular "l. "phoral organs" are prepared with great care by native methods, only the mature fibres from the under-side of the leaves being taken. These are collected in water, scraped over the edge of a shelf to free them from adhering cellular tissue and epidermis, and more than once washed in a running stream, followed by renewed scraping till the desired purity of fibre is attained. This native process is exceedingly wasteful, not more than one-fourth of the leaf-fibre being there-by utilised. But up till 1860 it was only native-prepared phoroniurn that was known in the market, and it was on the material so carefully, but wastefully, selected that the reputation of the fibre was built up. The troubles with the Maoris at that period led the colonists to engage in the industry, and the sudden demand for all available fibres caused soon afterwards by the Civil War in America greatly stimulated their endeavours. Machinery was invented for disintegrating the leaves and freeing the fibre, and at that day some experiments were made with the view of obtaining it by water-retting, and by means of alkaline solutions and other chemical agencies. But the fibre produced by these rapid and economical methods was very inferior in quality to the product of Maori handiwork, mainly because weak and undeveloped strands are, by machine preparation, unavoidably intermixed with the perfect fibres, which alone the Maoris select, and so the uniform quality and strength of the material are destroyed. The New Zealand government, in 1893, offered a premium of £575 for a machine which would treat the fibre satisfactorily, and a further £500 for a process of treating the tow; and with a view to creating further industrial usefulness of the raw material. In 1896 the New Zealand authorities placed an order for 200 tons of native flax for England during 1897. The premium was again issued in 1899.

In 1903 it was stated that a German chemist had discovered a method of working and spinning the New Zealand fibre. An idea of the extent of the growth of the fibre may be gathered from the fact that the exports for 1905 amounted to 28,877 bales at a value of nearly £700,000.

Phoroniurn is a cream-coloured fibre with a fine silky gloss, capable of being spun and woven into many of the heavier textures for which flax is used, either alone or in combination with flax.

It is, however, principally a cordage fibre, and in tensile strength it is second only to manila hemp; but it does not bear well the action of wet and dry to which cotton ropes are subject. The fibre has come into use as a suitable material for binder-twine as used in self-binding reaping machines.

PHORONIDEA, a zoological order, containing a single genus Phoronis, which is known to be of practically world-wide distribution, while there are many records of its larva, Actinothoe, from localities where the adult has not been found. Phoronis is often gregarious, the tubes which it secretes being sometimes intertwined in an inextricable mass. These associations of individuals can hardly be the result of the metamorphosis of a corresponding number of larvae, but are probably due to a spontaneous fragmentation of the adult animals, each such fragment developing into a complete Phoronis (De Selys-Longchamps). The animal is from a quarter of an inch to six inches (P. australis) in length. The free end of the long vermiform body ends in a horseshoe-shaped "lophophore," or tentacle-bearing region (fig. 1, a, b), which strikingly resembles that of the Phylactolaematae Polyzoa (see Polyzoa).

In this species (figs. 2, 3) the two ends of the lophophore are rolled into a crescent-shaped region (fig. 2, a), which bears the mouth (m), continuous on either side with the groove between the two series of tentacles; the anus (a), in the middle line, at no great distance from the mouth; a transversely elongated epistome (ep), between the mouth and the anus; and, in the concavity of the lophophore, the apertures of the nephridia (n.e.o.) which, according to De Selys-Longchamps, open into the two large sensory or glandular organs (g.l.), the orthaen of which are seen at gl. The mouth leads into the nephophagus, which extends straight down the body nearly to the aboral end or "amphulla," where it dilates into a stomach, from which the ascending limb of the J-shaped alimentary canal passes directly to the anus. The coelomic body-cavity is divided by a transverse septum (fig. 3, s) which lies near the bases of the tentacles. The preseptal or lophophoral coelom is continued into each of the tentacles and into the body-wall. Each nephridium is provided with either one or two funnels which open into the postseptal division of the coelom (n.e.f.). The nervous system lies in the epidermis, externally to the basement-membrane. A general nerve-plexus probably exists over considerable parts of the skin, and there are special nervous concentrations in the region of the epistome and along a double crescent (N) which follows the parietal attachment of the coelomic septum. The part which lies at the base of the epistome is morphologically dorsal in position. It is said by Schultz (11) to develop, in specimens which are regenerating the lophophoral end, from an invagination of the ectoderm; and in this condition is compared by him with

An oblique septum which follows the bases of the tentacles and corresponds with that of the adult animal divides the body-cavity into two portions. The postseptal division is a coelomic space, partially subdivided by a ventral mesentery. The preseptal cavity is a vascular space, since it is in free communication with the dorsal vessel of the larva, and it persists in part as the two lophophoral vascular crescents of the adult. It contains two tubfs of peculiar excretory cells, described by Goodrich (5) as "solenoids." These pass backwards through the septum and open to the exterior ventrally. After the Actinotrocha has led a pelagic life for some time it develops a large ventral invagination of its body-wall (fig. 4, 2, iv). At the metamorphosis, this sac is erected and the alimentary canal is drawn into it in the form of a loop (fig. 4, 3, 4). Most of the praetentacular region and the larval tentacles separate off, being then taken into the alimentary canal, where they are digested. The relations of the surfaces after their separation are clearly very different from those which obtained in the larva. The dorsal surface of the adult is the one between the mouth and the anus, while the median ventral line is the one which corresponds with the convexity of the alimentary canal. This view of the surfaces is, however, disputed by De Selys-Longchamps, who regards the aboral extremity of the adult as the posterior end.

The development of Phoronis was supposed by Caldwell (2) to furnish the explanation of the relations of the surfaces in Brachiopoda, Polyzoa and perhaps the Sipunculoid Gephyrae, in which the ontogenetic evidence is less clear. Caldwell's views were accepted by Lankester (8) in the 9th edition of this work, the Phylum Podaxonia being there instituted to include the groups just mentioned, together with the Pterobranchia. The peduncle of the Brachiopoda was supposed to correspond with the everted ventral pouch of Actinotrocha. As they had no doubt of the want of any complete investigation of the development of the Brachiopoda, and by the absence of the anus in the majority of the genera, there is, however, a considerable amount of resemblance between the lophophore of Phoronis australis, with its spirally twisted ends, and that of a typical Brachiopod; nor do the structural details of the adult Brachiopods forbid the view that they may be related to Phoronis. The comparative study of the development does not support the hypothesis that the Polyzoa (q.v.) are comparable with Phoronis. In Pedicellina, the only Polyzoa in which the alimentary canal of the larva is known to become that of the first adult individual, the line between the mouth and anus is ventral in the larva; and since there is no reversal of the curvature of the digestive loop during the metamorphosis it must be regarded as ventral in the adult. There are, indeed, remarkable similarities between the alimentary canals of the Phylactolaematus Polyzoa and the Phoronidea, and notably between their lophophores. The supposed occurrence of a pair of nephridia in certain Phylactolaemata, in a position corresponding with that of the nephridia of Phoronis, must also be mentioned.

Although it has been maintained that the "nephridia" of Phylactolaemata are merely ciliated portions of the body-cavity and not indeed nephridia at all. But a serious objection to the comparison is that the development of Phylactolaemata can be explained by supposing it to be a modification of what occurs in other Polyzoa, while it appears to have no relation whatever to that of Phoronis. Many observers consider that Actinotrocha is a highly modified Trochosphere, and this would give it some claim to be regarded as distantly related to the Entoproct Polyzoa and to other groups which have a Trochosphere larva.

- **b.t.** Basal part of oral tentacles.
- **m.** Mouth.
- **b.e.** Everted vessel which bifurcates at its base (see fig. 3). One of these branches communicates with the afferent lophophoral vessel, while the other one opens into the crescentic efferent lophophoral vessel (e.v.). From this the blood passes into two lateral vessels which pierce the coelomic septum (s.), the right vessel proceeding on the anterior side of the oesophagus, as shown in fig. 3, to effect a union with the left one, and thus to constitute the main efferent vessel, which gives off numerous cecal branches as it passes down the body. Hence the blood returns once more to the afferent vessel through a splanchic sinus which surrounds the stomach.

The circulation is maintained by the rhythmical contraction of the afferent vessel and by less regular contractions of some of the other vessels. The reproductive organs lie on the left side, near the aboral end, both ovary and testis being present in the same individual in some of the species. They are said to be developed from the coelomic epithelium which covers the efferent vessel or its caeca. The reproductive cells pass to the exterior by means of the nephridia. Reproduction by budding does not occur, although spontaneous fragmentation of the body, followed by complete regeneration of each of the pieces, is known to take place. Regeneration of the tentacular end of the animal is of frequent occurrence.

**Development and Affinities.** — The eggs of Phoronis are small and usually undergo their early development attached to the tentacles of the adult. The attachment is probably effected (Masterman) by the secretion of the lophophoral organs (fig. 2, gl). After the formation of an invaginate gastrula the larval form is rapidly acquired. On quitting the shelter of the parent tentacles the embryo becomes a pelagic larva, known as Actinotrocha (fig. 4) characterized by the possession of a line of tentacles running obliquely round the body. Locomotion is effected principally by means of a posterior ring of cilia surrounding the anus. The mouth (o) is in front of the tentacles, on the ventral side, and is overhung by a mobile praeoral hood, in which is the principal part of the nervous system.
PHORORHACOS—PHOSPHATES

Phororhacis has long been regarded as a possible ally of Rhabdopleura (see Pterobranchia); and Masterman (10) has attempted to demonstrate which the pseudocoelom which occur in the Pterobranchia. According to his view the pseudocoelom of Actinotrocha (cf. fig. 4) corresponds with the "proboscis" of Pterobranchia, the succeeding region, as far as the nesting of the tentacles with the collar at the post-tentacular region with the metasome. Masterman's more detailed comparisons have for the most part been rejected by other morphologists. One of the most formidable difficulties in the way of the attempt to reduce Actinotrocha to the Pterobranchiate type of structure is the condition of the coelom in the former. There is indeed a perfectly definite transverse septum which divides the body-cavity in the region of the tentacles. Even here it is admitted that the post-septal space may be the metasomatic cavity, the prae septal space can hardly be regarded as coelomic in nature, since it is in continuity with the vascular system; while Masterman's conclusion that the cavity of the praeoral hood (the supposed proboscis-cavity) is separated from that of the supposed collar has received no confirmation. In spite of these difficulties it must be conceded that the dominant flexure of the alimentary canal in the Pterobranchia is very Phororhacis. It has, moreover, been shown (especially Goodrich, 5) that shortly before its metamorphosis, Actinotrocha develops a coelomic space which lies immediately in front of the oblique septum, and gives rise later to the cavity of the lophophore and tentacles. Regarding this as a coelar-cavity, it becomes possible to agree with Masterman that the region shown in fig. 4, 1, between the tentacles and the praeoral hood, is really a collar the commencement of which is in the cavity of the proboscis. It will be shown that the lophophore of Phororhacis is, on this assumption, a derivative of the collar just as it is in the Pterobranchia. The epistome of the adult Phororhacis cannot well be the proboscis since its cavity is confluent with the lophophoral coelom; but because the praeoral hood of Actinotrocha is entirely lost at the metamorphosis. It is possible that this conclusion will account for the want of an anterior body-cavity in Phororhacis. Since the proboscis is a larval organ in this genus, it may be supposed that the coelomic space which properly belongs to it fails to develop, but that the præoral hood itself is none the less the morphological representative of the proboscis. In spite of the criticisms which have been made on the conclusion that Phororhacis is allied to the Pterobranchia, it is thus possible that the view is a sound one, and that the Phororhacidae should take their place, with the Enteropneusta and the Pterobranchia, as an order of the Hemichordata.

(S. F. H.)

PHORORHACOS, the best-known generic of the extinct Patagonian Stereostromes (see Bird: Fishes). Among the forms found in the strata of the Santa Cruz formation (now considered as mainly of mid-Miocene date) was the piece of a mandible which F. Ameghino described in 1887 as that of an edentate mammal, under the name of Phororhacis longissimius (Bolet. Mus. de la Plata, i. 225). In 1891 (Rev. Argent. Hist. Nat. i. 225) he amended the name and recognized the bone as that of a bird, Phororhacos, which with Brytornis and others constituted the family Phororhacidae. About six species of the type genus are now known, the most complete being Ph. inflatus, with skull, mandible, pelvis, limbs and some of the vertebrea.

These birds were at first considered as either belonging to the Ratitae, or at least related to them, until C. W. Andrews, after much of the interesting material had been acquired by the British Museum, showed the general affinities of Phororhacos (Ibis, 1896, pp. 1-12), a conclusion which he was able to further corroborate by the clearing of the adherent bone matrix from the skulls (Tr. Z. S. 1901, xx. pp. 55-86, pls. 1-3). The bill of Ph. longissimius is about 2 ft. long and 10 in. high; that of Ph. inflatus is 13 in. long, and this creature is supposed to have stood only 3 ft. high at the middle of the back. The under jaw is slightly curved upwards and it contains a large foramen as for instance in Psophia and in Mycteria. The strongly hooked upper beak is very high, and very much compressed laterally. The palate is imperfectly desmognathous, as in Diculophus, with an inconspicuous vomer. The quadrate has a double knob for its articulation with the skull, and basipterygoid processes are absent. What little is known of the shoulder-girdle (breastbone still unknown) points to a flightless bird, and so do the short wing bones, although these are stout. The pelvis has an ischiadic foramen. The hind limbs are distinctly slender, the tibia of Ph. inflatus being between 15 and 16 in. in length.

For further detail see F. Ameghino, "Sur les oiseaux fossiles de la Patagonie," Bolet. inst. geogr. argentino, xvi., chs. 11 and 12 (1895); F. P. Moreno and A. Mercader, Catálogo de los pajaros de la República Argentina, An. Mus. La Pintor (1897) with 21 plates.

PHOSGENE, a rare mineral consisting of lead chlorurate, (PbCl2)CO3. The tetragonal (holosymmetric) crystals are prismatic or tabular in habit, and are bounded by smooth, bright faces: they are usually colourless and transparent, and have a brilliant adamantine lustre. Sometimes the crystals have a curious helical twist about the tetrad or principal axis. The hardness is 3 and the specific gravity 6-3. The mineral is rather soft, and consequently was early known as "corneous lead" (Ger. Hornblei). The fanciful name phosgene was given by A. Breithaupt in 1820, from phosgene, the old name of carbon oxychloride, because the mineral contains the elements carbon, oxygen and chlorine. At Cromford, near Matlock, it was long ago found in an old lead mine, being associated with anesite and matlockite (PbSO4Cl) in cavities in decomposed galena; hence its common name hornblende. Fine crystals are also found in galena at Monteponi near Iglesias in Sardinia, but the largest are those recently found near Dundas in Tasmania. Crystals of phosgene, and also of the corresponding bromine compound [PbBr2]CO3, have been prepared artificially.

(L. J. S.)

PHOSPHATES, in chemistry, the name given to salts of phosphoric acid. As stated under PHOSPHORS, phosphoric oxide, P2O5, combines with water in three proportions to form H3O-P2O5 or HPO3, metaphosphoric acid; 2H2O-P2O5 or H2PO4, pyrophosphoric acid; and 3H2O-P2O5 or H3PO4, orthophosphoric or ordinary phosphoric acid. These acids each give origin to several series of salts, those of ordinary phosphoric acid being the most important, and, in addition, are widely distributed in the mineral kingdom (see below under Mineral Phosphates). Orthophosphoric acid, H3PO4, a tribasic acid, is obtained by boiling a solution of the pentoxide in water; by oxidizing red phosphorus with nitric acid, or yellow phosphorus under the surface of water by bromine or iodine; and also by decomposing a mineral phosphate with sulphuric acid. It usually forms a thin syrup which on concentration in a vacuum over sulphuric acid deposits hard, transparent, rhombic prisms which melt at 47°. On long heating the syrup is partially converted into pyrophosphoric and metaphosphoric acids, but on adding water and boiling the orthophosphoric acid is again formed. The chief classes of salts: M2H4PO4 or M2H2PO4; M2HPO4 or M2H2PO4; M3P2O7 or M3P2O7 or M3P2O7, wherein M,M,M denote a mono, di, and tri-valent metal. The first set may be called monometallic, the second dimetalllic, and the third trimetalllic salts. Per-acid salts of the alkalies, e.g. (KNaNH4)H2PO4, are also known; these may be regarded as composed of a monometallic phospho-
Phosphates

with phosphoric acid, thus $\text{M}_2\text{H}_2\text{PO}_4$, $\text{H}_3\text{PO}_4$. The three principal groups differ remarkably in their behaviour towards indicators. The monometallic salts are strongly acid, the dimetallic are neutral or faintly alkaline, whilst the soluble trimetallic salts are strongly alkaline. The monometallic salts of the alkaline and alkaline earths may be obtained in crystal form, but those of the heavy metals are only stable when in solution. The soluble trimetallic salts are decomposed by carbonic acid into a dimetallic salt and an acid carbonate. All soluble orthophosphates give with silver nitrate a characteristic yellow precipitate of silver phosphate, $\text{Ag}_3\text{PO}_4$, soluble in ammonia and in nitric acid. Since the reaction with the acid salts is attended by liberation of nitric acid: $\text{Na}_2\text{H}_2\text{PO}_4 + 3\text{AgNO}_3 = \text{Ag}_3\text{PO}_4 + 2\text{NaNO}_3 + \text{HNO}_3$, $\text{Na}_2\text{H}_2\text{PO}_4 + 3\text{AgNO}_3 = \text{Ag}_3\text{PO}_4 + 2\text{NaNO}_3 + \text{HNO}_3$, it is necessary to neutralize the nitric acid if the complete precipitation of the phosphoric acid one fixed and the second is soluble in acids but highly insoluble in ammonia solutions, and on heating to redness gives magnesium pyrophosphate, $\text{MgP}_2\text{O}_7$; uranic nitrate and ferric chloride, which gives a yellowish-white precipitate, soluble in hydrochloric acid and ammonia, but insoluble in acetic acid; mercurous nitrate which gives a white precipitate, soluble in nitric acid, and bismuth nitrate which gives a white precipitate, insoluble in nitric acid.

**Pyrophosphoric acid**, $\text{H}_3\text{P}_2\text{O}_7$, is a tetrabasic acid which may be regarded as derived by eliminating a molecule of water between two molecules of ordinary phosphoric acid; its constitution may therefore be written $(\text{HO})_2\text{P}-\text{O}-\text{P}(\text{O})\text{OH}$. It may be obtained as a glassy mass, indistinguishable from metaphosphoric acid, by heating phosphoric acid to 215°. When boiled with water it forms the ortho-acid, and when heated to redness the meta-acid. After neutralization, it gives a white precipitate with silver nitrate. Being a tetrabasic acid it can form four classes of salts; for example, the four sodium salts $\text{Na}_2\text{P}_2\text{O}_7$, $\text{NaH}_2\text{P}_2\text{O}_7$, $\text{Na}_2\text{H}_2\text{P}_2\text{O}_7$, $\text{NaH}_3\text{P}_2\text{O}_7$ are known. The most important is the normal salt, $\text{Na}_2\text{P}_2\text{O}_7$, which is readily obtained by heating disodium orthophosphate, $\text{Na}_2\text{HPO}_4$. It forms monoclinic prisms (with $10^{4}$O) which are permanent in air. All soluble pyrophosphates when boiled with water for a long time are converted into orthophosphates.

**Metaphosphoric acid**, $\text{H}_3\text{P}_2\text{O}_5$, is a monobasic acid which may be regarded as derived from orthophosphoric acid by the abstraction of one molecule of water, thus $\text{H}_3\text{PO}_4 - \text{H}_2\text{O} = \text{H}_3\text{P}_2\text{O}_5$; its constitution is therefore $(\text{HO})\text{PO}_4$. The acid is formed by dissolving phosphorus pentoxide in cold water, or by strongly heating orthophosphoric acid. It forms a colourless vitreous mass, hence its name "glacial phosphoric acid." It is readily soluble in water, the solution being gradually transformed into the ortho-acid, a reaction which proceeds much more rapidly on boiling. Although the acid is monobasic, salts of polymeric forms exist of the types $(\text{MPO}_4)_n$, where $n$ may be 1, 2, 3, 4, 6. They may be obtained by heating a monometallic orthophosphate of a fixed base, or tri- or tetracalcium metaphosphate of metallic salts in the cold, e.g. microcosmic salt: $\text{M}_2\text{H}_2\text{PO}_4 + \text{H}_2\text{O} (\text{NH}_4)\text{Na}_2\text{HPO}_4 = \text{Na}_2\text{P}_2\text{O}_5 + \text{NH}_3 + \text{H}_2\text{O}$; they may also be obtained by acting with phosphoric pentoxide on trimetallic orthophosphates: $\text{Na}_2\text{PO}_4 + \text{P}_2\text{O}_5 = 2\text{Na}_2\text{PO}_5$. The salts are usually non-crystalline and fusible. On boiling their solutions they yield orthophosphates, whilst those of the heavy metals in boiling water give a trimetalllic orthophosphate and orthophosphoric acid: $3\text{Ag}_2\text{PO}_4 + 3\text{H}_2\text{O} = 2\text{Ag}_3\text{PO}_4 + 2\text{H}_3\text{PO}_4$. On heating with an oxide or carbonate they yield a trimetallic orthophosphate, carbon dioxide being evolved in the latter case. Metaphosphoric acid can be distinguished from the other two acids by its power of coagulating albumen, and by not being precipitated by magnesium and ammonium chlorides in the presence of ammonia. (C. E. S.)

**Mineral Phosphates.**—Those varieties of native calcium phosphate which are not distinctly crystallized, like apatite (q.v.), but occur in fibrous, compact or earthy masses, often nodular, and more or less impure, are included under the general term phosphorite. The name seems to have been given originally to the Spanish phosphorite, probably because it phosphoresced when heated. This mineral, known as Estremadura phosphorite, occurs at Logrossan and Cáceres, where it forms an important deposit distributed in-land in the north of the province of Cáceres, and has about 7% of calcium phosphate, with about 2% of magnesium phosphate. A somewhat similar mineral, forming a fibrous incrustation, with a mammillary surface, and containing about 9% of calcium carbonate, is known as staffelite, a name given by A. Stein in 1866 from the locality Staffel, in the valley of the Lower Lahn, where (as also in the valley of its tributary the Dill) large deposits of phosphorite occur. Dahlite is a Norwegian phosphorite, containing calcium carbonate, named in 1888 by W. C. Brøgger and H. Bæckstrøm after the Norwegian geologists T. and J. Dahl. Osteolite is a white earthy phosphorite occurring in the cliffs of Breskvar rocks, named in 1851 by J. C. Bromeis from the Greek ὄστεος, bone.

Phosphorite, when occurring in large deposits, is a mineral of much economic value for conversion into the superphosphate largely used as a fertilizing agent. Many of the impure substances thus utilized are not strictly phosphorite, but pass under such names as "rock-phosphorite," or, when nodular, as "coprolite" (q.v.), even if not of true coprolite origin. The ultimate source of these mineral phosphates may be referred in most cases to the apatite widely distributed in crystalline rocks. Being soluble in water containing carbonic acid or organic acids it may be readily removed in solution, and may thus furnish plants and animals with the phosphates required in their structures. On the decay of these structures the phosphates are returned to the inorganic world, thus completing the cycle.

There are three sources of phosphates which are of importance geologically. They occur (a) in crystalline igneous and metamorphic rocks as an original constituent, (b) in veins associated with igneous rocks, and (c) in sedimentary rocks either as organic fragments or in secondary concretionary forms.

The first mode of occurrence is of little significance practically, for the crystalline rocks generally contain too little phosphorus to form a source of fertilizer. Of the other two the most important is that of enough apatite to form an inferior fertilizing agent, e.g. the trachyte of Cabo de Gata in south-east Spain, which contains 12–15% of phosphoric acid. In many deposits of iron ores found in connexion with igneous or metamorphic rocks small quantities of phosphorus occur. The Swedish, Norwegian, Ontario and Michigan mines yield ores of this kind; and though none of them can be profitably worked as a source of phosphate, yet on reducing the ore it may be retained in the slags, and thus rendered available for agriculture.

Another group of phosphtic deposits connected with igneous rocks comprises the apatite veins of south Norway, Ottawa and other localities in Canada. These are of pneumolysis origin (see Pneumatolysis), and have been formed by the action of vapours emanating from cooling bodies of basic eruptive rock. Veins of this type occur at Oedegarden in Norway and Dunder in Lapland. From 1500 to 3000 tons of apatite are obtained yearly in Norway from these veins. In Ontario apatite has been worked for a long time in deposits of similar nature. The total output of Canada in 1907 was only 680 tons.

A third group of localities in which phosphate occurs among the sedimentary strata are the principal sources of phosphates for commerce and agriculture. They are found in formations of all ages from the Cambrian to those which are accumulating at the present day. Of the latter the best known is that in the Barroe district of Manchuria.

Where guano-beds are exposed to rain their soluble constituents are removed and the insoluble matters left behind. The soluble phosphates washed out of the guano may be regenerated by entering into combination with the elements of the rock beneath. Many of the oceanic islands are composed of coral limestone, in which this
PHOSPHORESCENCE

way becomes phosphatized; others are igneous, consisting of trachyte or basalt, and these rocks are also phosphatized on their surfaces or at suitable places, inasmuch as the presence of iron or alumina in any quantity renders them unsuited for the preparation of artificial manures.

The leached guano and phosphatized rocks, which are grouped with them in the Maltese deposits, have been obtained in great quantities in many islands of the Pacific Ocean (such as Baker, Howland, Jarvis and McKean Islands) between long. 150° to 180° W. and lat. 10° N. to 10° S. In the West Indies from Venezuela to the Bahamas and in the Caribbean sea, many islands yield supplies of leached guano; the following are important in this respect: Sombrero, Navassa, Aves, Aruba, Curacao. Christmas Island has been a great source of phosphates of this type; W. Java, the Philippine Islands, the Andaman and Nicobar Islands, the Moluccas and in Kure are also important sources.

It has been estimated that 500,000 tons of phosphate were obtained in Aruba, 1,000,000 tons from Curacao since the deposits were discovered in 1870, and Christmas Island in 1907 yielded 290,000 tons.

In the older formations the phosphates tend to become more and more mineralized by chemical processes. In whatever formations they are originally deposited they often suffer complete or partial solution and are redeposited as concretionary lumps and nodules, often called coprolites. The "Challenger" and other oceanographic expeditions have shown that on the bottom of the deep sea concretions of phosphate are now gathering around the dead bodies of fishes lying in the ooze; consequently the formation of the concretions may have been carried on simultaneously with the deposition of the strata in which they occur.

Important deposits of mineral phosphates are now worked on a large scale in the United States, the annual yield far surpassing that of any other part of the world. The most active operations are carried on in Florida, where the phosphate was first worked in 1887 in the form of pebbles in the gravels of Peace River. Then followed the discovery of "hard rock phosphate," a massive mineral, often having cavities lined with nearly pure phosphorite. Other kinds not distinctly hard and consisting of less rich phosphatic limestone, are known as "soft phosphate": those found as smooth pebbles of variable colour are called "land phosphate," whilst the pebbles of the river-beds and old river-valleys, usually of dark colour, are distinguished as "river phosphate." The land phosphate is worked in central South Florida; the hard rock chiefly between Miami and Key West, and the phosathonite boundaries in Carolina. There are important deposits of phosphate, formerly more productive than at present, the "land rock" is worked near Charleston, and the "river rock" in the Coosa river and other streams near Beaufort. The phosphate beds contain Eocene fossils derived from the underlying strata and many fragments of Pleistocene vertebrata such as mastodon, elephant, stag, horse, pig, &c. The phosphate occurs as lumps varying greatly in size, scattered through a sand or clay; they often contain phosphatized Eocene fossils (Mollusca, &c.). Sometimes the phosphatized lumps are found at the surface, generally it is covered by alluvial sands and clays. Phosphate mining began in South Carolina in 1866 and passed into Georgia, where the principal producer. Then the Florida deposits began to be worked. In 1892 the phosphates of Tennessee, derived from Ordovician limestones, came into the market. From North Carolina, Alabama and Pennsylvania, also, phosphates have been obtained but only in comparatively small quantities. In 1900 mining for phosphates was commenced in Arkansas. In 1908 Florida produced 1,073,651 tons of phosphate valued at 11 million dollars. All the other states together produce less phosphate than Florida, and among them Tennessee takes the first place with an output of 493,180 tons.

Algeria contains important deposits of phosphorite, especially near Tebesa and at Tocqueville in the province of Constantine. Near Jebel Koutif, on the frontier between Algeria and Tunisia, there are phosphate workings, as also in Tunis, at Gafsa. The deposits belong to the Lower Eocene, where it rests unconformably upon the Cretaceous. The joint production of Tunis and Algeria in 1907 was not less than a million.

Phosphate rocks occur also in Egypt, in the desert east of Keneh and in the Dakla oasis in the Libyan desert.

France is rich in mineral phosphates, the chief deposits being the departments of the Pas-de-Calais, Somme, Aisne, Oise in and Meuse, in the north-east, and another group in the departments of Lot, Tarn-et-Garonne and Aveyron, in the south-west: the phosphates occur chiefly near Puy-de-Dôme, where the lumps of Calvias and in Quercy occupy fissures and pockets in Jurassic limestone, and have yielded a remarkable assemblage of the relics of Tertiary mammals and other fossils. Phosphates occur in Belgium, especially near Mons, and these, like those of north-east France, are principally in the Upper Chalk. Two varieties of phosphate rock are recognized in these districts, viz. the phosphatic chalk and the phosphate sand, the latter resulting from the decomposition of the former. Large and valuable deposits of the sand have been obtained in sinks and depressions on the surface of the chalk. The production is on the whole diminishing in Belgium (180,000 tons in 1907), but in France it is still large (375,000 tons in 1907).

In the Lahn district of Nassau (Germany) there are phosphate beds in Devonian rocks. The deposits were rich but irregular, and local, and were much worked from 1866 to 1884, but are no longer of economic importance. In northern Estremadura in Spain and Alemtezo in Portugal there are veins of phosphate of lime. As much as 200,000 tons of phosphate have been raised in these provinces, but in 1906 the total production of Spain was only 1300 tons. Large deposits of phosphate occur in Russia, and those in the neighbourhood of Kertch have attracted some attention; it is said that the Cretaceous rocks between the rivers Don and Volga contain very large supplies of phosphate, though probably of low grade.

Phosphatic nodules and concretions, with phosphatized fossils and their casts, occur at various geological horizons in Great Britain. Bands of black nodules, highly phosphatic, are found at the top of the Bala limestone in North Wales; beds of concretions occur in the Lower Lias at Lyme Regis, and important deposits are known in the Cretaceous strata, especially in the Lower Greensand and at the base of the Gault. The Lower Greensand phosphates have been worked, under the name of "coprolites," at Potton in Bedfordshire and at Upware and Wicken in Cambridgeshire. The Cambridge Greensand, rich in phosphatic nodules, occurs at the base of the Chalk Marl. The chalk occasionally becomes phosphatized, as at Taplow (Bucks) and Lewes (Sussex). At the base of the Red Crag at South Weald, in Essex, and at the base of the purple beds of the Crags, there is a nodule bed, consisting of phosphatic nodules, with rolled teeth and bones, which were formerly worked as "coprolites" for the preparation of artificial manure. Professor J. J. Petts has found that phosphatized nodules, besides phosphates, contain radioactive constituents, and has brought this into relation with their geological age.

(J. S. F.; W. R.)

PHOSPHORESCENCE, a name given to a variety of physical phenomena due to different causes, but all consisting in the emission of a pale, more or less ill-defined light, not obviously due to combustion. The word was first used by physicists to describe the property possessed by many substances of themselves becoming luminous after exposure to light. This property of phosphorescence is a property of inorganic substances, usually crystals, which shine with a light of their own, and Albertus Magnus knew that the diamond becomes phosphorescent when moderately heated. But the first discovery of this property which apparently attracted scientific attention seems to have been that of the Bologna stone (barium sulphide), which was discovered
by Vincenzo Casciarolo, a cobbler of Bologna, in about 1602. This was followed by the discovery of a number of other substances which become luminous either after exposure to light, or on heating, or by attrition, and to which the general name of "phosphor" (from φως and φόρος, bringing light) was given. Among these may be mentioned Homberg's phosphor (calcium chloride), John Canton's phosphor (calcium sulphide) and Baldini's phosphor (calcium nitrate). Of late years it has been found convenient to limit the strict meaning of the word "phosphorescence" to the case of bodies which, after exposure to light, become self-luminous (even if only for a fraction of a second). The general term "luminescence" has been proposed by W. K. and J. W. *Kirkwood* to include all cases in which bodies give off light not due to ignition. The term "luminescence" embraces several subdivisions. Thus, fluorescence (q.v.) and phosphorescence (q.v.) are included under the same heading, "photoluminescence," being distinguished from each other by the fact that fluorescent bodies emit their characteristic light only while under the influence of the exciting illumination, while phosphorescent bodies are luminous for an appreciable time after the exciting light is cut off.

Phosphorescence, in its restricted meaning as above explained, is most strikingly exhibited by the artificial sulphides of calcium, strontium, and barium, which are exposed for some time to daylight, or, better, to direct sunlight, and then placed in the dark. When the temperature of the electric arc, it will shine for hours in the dark with a soft, as to coloured light. The colour depends not only on the nature of the substance, but also on its physical condition, as is shown, for instance, on luminous paint, a preparation of calcium sulphide, shines with a white light. The colour also depends on the temperature during exposure to the light. Thus A. E. Becquerel found that the light given by a specimen of sulphur yellow in strength from blue to white, green, and orange, as the temperature during the corresponding previous insolation was 20°, 40°, 70°, 100° or 200° C. The duration of this phosphorescence is very greatly with different substances. It may last for days or for only a fraction of a second.

As in the case of fluorescent bodies, the light produced by phosphorescent substances consists commonly of rays less refrangible than those of the exciting light. Thus the ultra-violet portion of the spectrum is usually the most efficient in exciting rays belonging to the visible part of the spectrum. V. Klatt and Ph. Lenard (Wied. Ann., 1889, xxxvii. 90), have shown that the phosphorescence of copper sulphide depends on the presence of minute quantities of other substances, such as copper, bismuth and manganese. The maximum intensity of phosphorescent light is obtained when a certain definite proportion of the impurity is present; the phosphorescent light diminishing as the proportion of impurities is increased.

It appears likely that when a phosphorescent body is exposed to light, the energy of the light is stored up in some kind of energy, and that the phosphorescent light is given out during a more or less long period. Klatt and Lenard have shown that the sulphides of the alkaline earths lose the property of phosphorescing when subjected to heavy pressure. Many fluorescent solutions become brightly phosphorescent when rendered solid by gelatin.

When the duration of phosphorescence is brief, some mechanical device becomes necessary to detect it. The earliest and best-known instrument for this purpose is Becquerel's phosphoscope. It consists essentially of a shallow drum, in which ends two eccentric holes, exactly opposite one another; a drum. Inside it are fixed two equal metal disks, attached perpendicularly to an axis, and distanced from each other. The alternate one is red or blue, each being cut out. One of these disks is close to one end of the drum, the other to the opposite end, and the sectors are so arranged that, when the disks are rotated, the hole in one end is open while that in the other is closed, and vice versa. If the disks be made to revolve, when the velocity is a little less than that of a train on wheels the object will be presented to the eye almost instantly after it has been exposed to sunlight, and these presentations succeed one after another so rapidly as to produce a sense of continuous vision. By this means we can consider the time during which the duration of the phenomenon after the light has been cut off. For this purpose we require to know merely the number of sectors in the disks and the rate at which they are turned.

**Thermoluminescence**—Some bodies which do not emit light at ordinary temperatures in a dark room begin to do so if they are heated to a temperature below a visible red heat. In the case of chlorophane, a variety of flower-spar, the heat of the hand is sufficient. Many yellow diamonds yield this form of luminescence which has been shown, however, that a previous exposure to light is always necessary. Sir James Dewar found that if ammonium platinocyanide and sodium ammonium cyanate are boiled in liquid air and exposed to light, they emit not phosphorescence, but as soon as they are allowed to warm up to the ordinary temperature they emit a brilliant light. On the other hand, some bodies, as copper, bismuth, tellurium, ceratium and ivory, are phosphorescent at very low temperatures, but lose the property at ordinary temperatures.

**Triboluminescence** (from tribo-, to rub) is luminescence excited by friction, percussion, or other mechanical agencies. Calcium, strontium, copper, and strontium carbonate, prepared at a red heat, exhibits this property. If sulfur is broken in the dark, or two crystals of quartz rubbed together, or a piece of mica cleft, a flash of light is seen, but this is probably due to the production of "crystal-luminescence," a phosphorescent light seen when some substances crystallize from solution or after fusion. This property is also exhibited by arsenic when crystallizing from solution in hydrochloric acid.

**Chemiluminescence** is the name given to those cases in which chemical action produces light without any great rise of temperature. Phosphorescent exposed to moist air in a dark room shines with a soft light due to slow oxidation. Decaying wood and other vegetable substances often exhibit the same property.

**Electroluminescence** is luminescence due to electrical causes. Many of the materials for a phosphorescent apparatus and discharge has been passed through them, and some solid substances, especially diamonds and rubies, are strongly phosphorescent when exposed to cathode rays in a vacuum tube.

**Phosphorescence in Zoology.**

The emission of light by living substance is a widespread occurrence, and is part of the general metabolism by which the potential energy introduced as food is transformed into kinetic energy and appears in the form of movement, heat, electricity and light. In many cases it is probably an accidental by-product, and like the heat radiated by living tissues, is not necessarily of use to the organism. But in other cases the capacity to produce light is awakened on stimulation, as when the retina is electrified by light, the eye of a fly or the electric eel. It has been suggested that the response to the stimulus may be protective, and that enemies are frightened by the flash of light. In luminous insects and deep-sea fish the power of emitting light appears to have a special significance, and very elaborate mechanisms have been developed. The pale glow of phosphorescence has a certain resemblance to the light emitted by phosphorus, and it was an early suggestion that the phenomenon in living organisms was due to that substance. Phosphorus, however, and its luminous compounds are deadly poisons to all living tissues, and never occur in them in the course of natural metabolism, and the phosphorescence of life cannot therefore be assigned to the organic constituents of the body. On the other hand, it is certainly the result of a process of oxidation, as the emission of light continues only in the presence of oxygen. J. H. Fabre showed in 1855 that the luminous fungus, _Aurigus_, discharges more carbonic acid when it is emitting light, and Max Schultz in 1865 showed that in insects the luminous cells are closely associated with the tracheae, and that during phosphorescence they withdraw oxygen from them. In 1880 B. Radziszewski showed that many fats, ethered oils and alcohols emit light when slowly combined with oxygen in alkaline fluids at appropriate temperatures. Probably the phosphorescence of organisms is due to a similar process acting on the many fats, oils and similar substances found in living cells. The colour varies much in different organisms; green has been observed in the glow-spar of fire-flies, brittle-stars, centipedes and annelids; blue in the Italic fish (Luciola ilicata); bright red and green are the predominant colours in the phosphorescence of marine organisms, but red and lilac have also been observed. The lantern-fly (Fulgura pyrophor us) is said to have a purple light, and E. H. Giddy has recorded that an individual _Appendicularia_ appeared first red, and then blue, and then green. P. Panceri, chiefly in the case of Salps, and S. P. Langley and F. W. Very in the case of _Pyrophorus_, have investigated the light spectroscopically, and
PHOSPHORITE—PHOSPHORUS

...found that it consisted of a continuous band without separate bright lines. The solar spectrum extends farther both towards the violet and the red ends, but is less intense in the green when equal luminosities are compared.

Many of the bacteria of putrefaction are phosphorescent, and the light emitted by dead fish or molluscs or flesh is probably due in every case to bacterial action. In the majority of these cases, individual bacteria appear as shining points of light. The phosphorescence of decaying wood is due to the presence of the mycelia of Agaricus melius, and various other species of Agaricus have been found to produce phosphorescence. In deep-sea water, sea-stars, and sea-anemones, also, phosphorescent cells are present; all these are usually due to the presence of very large numbers of small luminous organisms, either protozoa or protophyta. Of these Noctilus miliaris and species of Peridinium and Pyrocystis are the most frequent, the two former near land and the latter in mid-ocean.

In higher animals the phosphorescence tends to be limited to special parts of the body which may form elaborate and highly specialized organs. In the cephalopods the light is produced by a fluid secreted by certain dermal glands. A similar fluid in other Lower Crustacea is also phosphorescent. Glands of this kind are also found in certain deep-sea fishes, discharging phosphoressence in tropical seas; it has two small patches of cells at the base of each inhalent tube which on stimulation discharge light, and the luminosity is observed to spread through the coelomic fluid of the animal. In the squid (Loligo), some cephalopods are phosphorescent. W. Giesbrecht has shown that the light is produced by a fluid secreted by certain dermal glands. A similar fluid in other Lower Crustacea is also phosphorescent. Glands of this kind are also found in certain deep-sea fishes, discharging phosphorescence in tropical seas; it has two small patches of cells at the base of each inhalent tube which on stimulation discharge light, and the luminosity is observed to spread through the coelomic fluid of the animal. In the cephalopods belonging to many families are luminous. A. Alcock in some of the deep-sea prawns a luminous secretion was discovered at the bases of the antennae, but in most cases the luminous organs are concentrated in structures characteristic of these animals.

The rock-boring mollusc, Pholas, which Pliny knew to be phosphorescent, has luminous organs along the anterior border of the mantle, two small triangular patches at the entrance of the anterior siphon, and two long parallel cords within the siphon. The cells of these organs have peculiar, granulated contents. W. E. Hoyle, in his presidential address to the Zoological Section of the British Association in 1997, brought together data of observations of phosphorescence in no less than thirty-three species of Cephalopods. In Heriteuthis, Sepiola and Rossia the light is produced by the secretion of a glandular organ on the ventral side of the organ, and by the fusion of the glandular cells with the transparent wall with a greenish colour, but, at least in the case of Heriteuthis, continues to glow after being ejected into the water. In most cases the luminous organs are nonglandular and may be simple, or possess not only a generator but a reflector, lens and diaphragm.

The different organs shine with different coloured lights, and as the Cephalopods are for the most part inhabitants of the depths of the sea, it has been suggested that they serve as recognition marks.

Some centipedes (e.g. Geophilus electricus and G. phosphorus) are phosphorescent, and, if allowed to crawl over the hand, are stated to leave a luminous trail. Amongst insects, elaborate luminous organs occur in several cases. The abdomen of a Cephalocera, May-fly (Tegenaria) is luminous. The so-called New Zealand "glow-worm" is the larva of the fly Boletophila luminosa, and some gnats have been observed to be luminous, although the suggestion is that in their case disease is present and the light emanates from phosphorescent bacteria. An ant (Orya) and a poduran (Asurophorus) are occasionally luminous. The so-called lantern flies are Halyomorpha. In the luminous glands of the lava lizards, a huge projection of the front of the head, regarding the luminosity of which there is some doubt. The glow-worms and tree-flies are beetles. Eggs, larvae and adults are in some cases luminous. The larvae of the false glow-worm, which gives the light, and a deeper layer which may act as a reflector. They are in close connection with the trachea and the light is produced by the oxidation of a substance formed under the influence of light. Thus the light produced is of the kind of phosphorescence in which the females the phosphorescence is probably a sexual lure; in the males its function is unknown. Phosphorescent organs known as phosphores are characteristic structures found in many organic and inorganic compounds. The phenomenon has been developed in widely different families (Stomatiidae, Scopelidae, Halotauridae and Anomalopidae), whilst numerous luminescent animals have been described. These are characteristic of the Mysidacea and the Crustacea, and the luminous organs are generally arranged in rows, sometimes metamerically distributed; the more complex organs are larger and less numerous. In Opisthopasias mirrurias there is a large organ on a median cleft hanging down from the chin, others on the eyes, and one on the side of the head. In S. fruticulosa the fin. In Sternoptyx diaphana there is one on the lower jaw, and in many species one or two below the eyes. The luminous organs appear to be specialized skin glands which secrete a fluid that becomes luminous on slow oxidation. The essential part of the organ remains a collection of gland cells, but as the more complex types there are blood vessels and nerves, a protecting membrane, an epithelium, a protruding gland and secretory pouch, and probably the colour of the light varies with the species, these organs may serve as recognition marks. They may also attract prey, and from their association with the eyes in such a position as to send light downwards and forwards it is probable that in the higher types they are used by the fish actually as lanterns in the dark abysses of the sea.

PHOSPHORITE, in mineralogy, the name given to impure massiveapatite (q.v.; see also Phosphates). PHOSPHORUS (Gr. φως, light, φερεν, to bear), the name originally given to any substance which possessed the property of phosphorescence (q.v.), i.e. the power of shining in the dark, but now generally restricted to a non-metallic element, which was first known as Phosphorus mirabilis or igneus. This element is very widely distributed in nature in combination, but is never found free. In the mineral kingdom it is exceptionally abundant, forming large deposits of phosphorites (q.v.). It is also necessary to animal and vegetable life (see MANURE). It occurs in the urine, blood, tissues, and bones of animals, calcium phosphate forming about 50% of bones, which owe their rigidity to its presence.

The element appears to have been first obtained in 1669 by Brand of Hamburg; Kraft bought his secret and in 1677 exhibited specimens in England, where it created an immense sensation. Its preparation was assiduously sought for, and Kunckel in 1678 and Boyle in 1686 succeeded in obtaining it by the same process as was discovered by Brand, i.e. by evaporating urine to dryness and distilling the residue with sand. This method was generally adopted until 1775, when Scheele prepared it from bones, which had been shown by Gahn in 1760 to contain calcium phosphate. Scheele treated bone ash with nitric acid, precipitated the calcium as sulphate, filtered, evaporated and distilled the residue with charcoal. Nicolas and Pelletier improved the process by decomposing the bone-ash directly with sulphuric acid; whilst Fourcroy and Vauquelin introduced further economies. In modern practice degreased bones (see GELATIN), or bone-ash which has lost its virtue as a filtering medium, &c., or a mineral phosphate is treated with sufficient sulphuric acid to precipitate all the calcium, the calcium sulphate filtered off, and the filtrate concentrated, mixed with charcoal, coke or sawdust and dried in a muffle furnace. The product is then distilled from Stourbridge clay retorts, arranged in a galley furnace, previously heated to a red heat. The temperature is now raised to a white heat, and the product fed by malleable iron pipes into condensing troughs containing water, when it condenses. The chemical reactions are as follows: the treatment of the calcium phosphate with the acid gives phosphoric acid, H3PO4, which at a red heat loses water to give metaphosphoric acid, H2PO3; this at a white heat reacts with carbon to give hydrogen, carbon monoxide and phosphorus, thus: 2H2PO+ 6C = H2+3CO+P3. Electrothermic processes are also employed. Calcium phosphate, mixed with charcoal and carbon, is fed into an electric furnace. The oxide is provided with a closely fitting cover with an outlet leading to a condenser. At the temperature of the furnace the silica (sand) attacks the calcium phosphate, forming silicate, and setting free phosphorus pentoxide, which is attacked by the carbon, forming phosphorus and carbon monoxide. As phosphorus boils at 290°C. (554°F.), it is produced in the form of vapour, which, mingled with carbon monoxide, passes to the
PHOSPHORUS

condenser, where it is condensed. It is then cast under water. The calcium silicate remains in the furnace in the form of a liquid slag, which may be run off, so that the action is practically continuous. Kaolin may with advantage be used with addition to or in part substitution for sand, because the double silicate thus formed is more fusible than the single silicate of lime. The alternating current is generally used, the action not being electrolytic. One of the special advantages of the electrical over the older process is that the distilling vessels have a longer life, owing to the fact that they are not externally heated, and so subjected to a relatively high temperature when in contact with the corrosive slag formed in the process. The Readman-Parker process (see Jour. Soc. Chem. Ind., 1891, x. 445) appears to be very generally adopted. Readman, experimenting with a Cowper furnace, published his observations in 1863, and in the same year Parker and Robinson, working independently, patented a similar one. The two inventors then cooperated, an experimental plant was run successfully, and the patents were taken over by the leading manufacturers. With the object of obtaining a valuable by-product in place of the slag produced in this furnace, several patentees (e.g. Hilbert and Frank, Billaudot, Bradley and Jacobs, and others) have sought to combine the manufacture of calcium carbide and phosphorus by using only calcium phosphate and carbon, effecting direct reduction by carbon at a high temperature.

The crude phosphorus is purified by melting under water and then filtering through animal black and afterwards through chamois leather, or by treating it, when molten, with chromic acid or a mixture of potassium bichromate and sulphuric acid; this causes the impurities to rise to the surface as a scum which can be skimmed off. It is usually sent on the market in the form of sticks, which were at one time prepared by sucking the molten material up glass tubes; but the dangers to the workmen and other disadvantages of this method have led to its replacement by a continuous process, in which the phosphorus leaves the melting-pot for a pipe surrounded by water, in which it solidifies and can be removed as a continuous rod.

Properties.—When perfectly pure phosphorus is a white, transparent, waxy solid, but as usually prepared it is yellowish owing to the presence of the allotropic “red phosphorus,” J. Böseken (Abs. Jour. Chem. Soc., 1907, ii. 343, 760) prepares perfectly pure phosphorus by heating the crude product with chromic acid solution, washing and drying in a vacuum, first at 40°, then at 80°. It remains colourless in vacuum tubes in the dark, but on exposure it rapidly turns yellow. At 25° to 30° C. it is soft and flexible, but it hardens when strongly cooled, and can then only be cut with difficulty. The fracture is distinctly crystalline; large crystals, either regular dodecahedra or octahedra, may be obtained by crystallisation from carbon bisulphide, sulphur chloride, &c., or by sublimation. It is a non-conductor of electricity. Its density at 0° is 1·836; this regularly diminishes up to the melting-point, 44-3°, when a sudden drop occurs. Molten phosphorus is a viscid, oily, highly refractive liquid, which may be supercooled to 32° before solidification. It boils at 209°, forming a colourless vapour which just about the boiling-point corresponds in density to tetratomic molecules, P4; at 1500° to 1700°, however, Biltz and Meyer detected dissociation into P2 molecules. Beckmann obtained P4 molecules from the boiling-point of carbon bisulphide solutions, and Hertz arrived at the same conclusion from the lowering of the freezing-point in benzene solution; E. Paternö and Nasini, however, detected dissociation. Phosphorus is nearly insoluble in water, but dissolves in carbon bisulphide, sulphur chloride, benzene and oil of turpentine.

The element is highly inflammable, taking fire in air at 34° and burning with a bright white flame and forming dense white clouds of the pentoxide; in perfectly dry air or oxygen, however, it may be distilled unchanged, H. B. Baker showing that a trace of water vapour was necessary for combination to occur. When exposed to the air a stick of phosphorus undergoes slow combustion, which is revealed by a greenish-white phosphorescence when the stick is viewed in the dark. This phenomenon was minutely studied by Boyle, who found that solutions in some essential oils (oil of cloves) showed the same character, whilst in others (oils of mace and aniseed) there was no phosphorescence. He also noticed a strong garlic-like odour, which we now know to be due to ozone. Frederick Slare noticed that the luminosity increased when the air was rarefied, an observation confirmed by Hawksbee and Homberg, and which was possibly the basis of Berzelius' theory that the luminosity depended on the volatility of the element and not on the presence of oxygen. Lampadius, however, showed that there was no phosphorescence in a Torricellian vacuum; and other experimenters proved that oxygen was essential to the process. It depends on the partial pressure of the oxygen and also on temperature. In compressed air at ordinary temperature there is no glowing, but it may be brought about by heating. Again, in oxygen under ordinary conditions there is no phosphorescence, but when exposed to 25° glowing occurs, as is also the case if the pressure be diminished or the gas diluted. It is also remarkable that many gases and vapours, e.g., Cl, Br, I,NH3, N2O, NO, H2S, SO2, CS2, CH3, C2H4, inhibit the phosphorescence.

The theory of this action is not settled. It is certain that the formation of hydrogen peroxide and ozone accompanies the glowing, and in 1848 Schönbein tried to demonstrate that it depended on the ozone. E. Jungfried (Comptes rendus, 1845, p. 444) suggested that it is due to the combustion of an oxide more volatile than phosphorus, a view which appears to be confirmed by the observations of Schonbein (Zeit. physik. Chem., 1850, xii. 117, p. 275) and of L. and E. Bloch (Comptes rendus, 1850, 147, p. 842).

The element combines directly with the halogens, sulphur and selenium, and most of the metals burn in its vapour forming phosphides. When finely divided it decomposes water giving hydrogen phosphide; it also reduces sulphurous and sulphuric acids, and when boiled with water gives phosphine and hypophosphoric acid; when slowly oxidized under water it yields hypophosphoric acid.

Allotropic Phosphorus.—Several allotropic forms of phosphorus have been described, and in recent years much work has been done towards settling their identities. When the ordinary form immersed in water is exposed to light, it gradually loses its transparency and becomes coated with a thin film. This substance was regarded as an allotrope, but since it is not produced in non-aerated water it is probably an oxide. More important is the so-called “red phosphorus,” which is produced by heating yellow phosphorus to about 230° for 24 hours in an inert atmosphere, or in closed vessels to 300°, when the change is effected in a few minutes. E. Kopp in 1844 and B. C. Brodie in 1853 showed that a trace of iodine also expedited the change. The same form is also produced by submitting ordinary phosphorus to the silent electric discharge, to sunlight or to ultra-violet light. Since this form does not inflame until heated to above 350°, it is manufactured in large quantities for consumption in the match industry. The process consists in heating yellow phosphorus in iron pots provided with air-tight lids, which, however, bear a long pipe open to the air. A small quantity of the phosphorus combines with the oxygen in the vessel, and after this the operation is practically conducted in an atmosphere of nitrogen with the additional safety from any risk of explosion. The product is ground under water, and any unchanged yellow form is eliminated by boiling with caustic soda, the product being then washed and dried and finally packed in tin boxes. The red variety is remarkably different from the yellow. It is a dark red microcrystalline powder, insoluble in carbon bisulphide, oil of turpentine, &c., and having a density of 2·2. It is stable to air and light, and does not combine with oxygen until heated to above 350° in air or 260° in oxygen, forming the pentoxide. It is also non-poisonous. When heated in a vacuum to 350° it sublimes, and on condensation forms microscopic needles.

Hittorf's phosphorus is another crystalline allotrope formed by heating phosphorus with lead in a sealed tube to redness, and removing the lead by boiling the product with nitric and
PHOSPHORUS

144; the = 1391); colourless forms and thus: solid 2RI+2PHJ 580. a first 430, 1088). black gives It E. = a hydrogen their freezing i): second decomposition a gases were putrefaction upon air, reducing gas, was obtained by Besson (Comptes rendus, 1896, p. 122, p. 123) from the alkalis with the iodides, and by heating amorphous phosphorus with concentrated hydroiodic acid solution to 165° C. It crystallizes in large cubes and sublimes readily. Water and the caustic alkalis readily decompose it with liberation of phosphorus and the formation of iodides or hydriodic acid. It is also decomposed by carbonyl chloride (Besson, loc. cit., 4PH3+8COCl2=16HCl+8CO+P14+2P).

Just as the amines are derived from ammonia, so from phosphine are derived the primary, secondary and tertiary phosphines, and phosphonium compounds by the exchange of hydrogen for alkyl groups, and corresponding to the phosphonium salts there exists a series of organic phosphonium bases. The primary phosphonium iodide is decomposed by the amine and is rapidly transformed into the primary phosphine and iodo-iodine acid (A. W. Hofmann, Ber., 1873, 6, p. 286). The reaction mixture, after treatment with water, yields the primary phosphine, the secondary being then liberated from its hydriodic acid by caustic soda. The tertiary phosphines, discovered by L. Thénard (Comptes rendus, 1832, 18, p. 414), are also formed by the interaction of phosphorus trichloride and zinc alkyls (Caubers and Hofmann, Ann., 1857, 104. p. 12): 2PCl3+Zn (CH3)2=3ZnCl+2P(C2H5)3. The primary and secondary phosphines are colourless compounds, and with the exception of methyl phosphine, are liquid at ordinary temperature. They possess an unpleasant odour, tinge on exposure to air, show a neutral reaction, and combine with water, even in small quantities, in many cases being spontaneously inflammable. On oxidation with nitric acid the primary compounds give monoalkyl phosphonic acids, RPO(OH)2, the secondary yielding dialkyl phosphonic acids, R2PO(OH), and the tertiary, trialkyl phosphorous acids, with weak bases, their salts with acids being readily decomposed by water. The tertiary phosphines are characterized by their readiness to pass into derivatives containing pentavalent phosphorus, and consequently they form additional compounds with sulphur, carbon bisulphide, chlorine, bromine, the halogen acids and the alkyl halides with great readiness. On oxidation they yield phosphine oxides, RP=O. The quaternary phosphonium salts resemble the corresponding nitrogen compounds. They are stable towards aqueous alkalis, but on digestion with moist silver oxide yield the phosphonous hydroxides, which are stronger bases than the caustic alkalis. They differ from the organic alkali hydroxides by the fact that they yield phosphine oxides and paraffin hydrocarbons: RP=OH=RP=O+RH. The boiling-points of some members of the series are shown in the table:

The alkyl phosphinic acids are colourless compounds which are easily soluble in water and alcohol. They yield two and four colourless phosphinic hydrochloric acid, and the diethyl phosphinic acids are also colourless compounds, the majority of which are insoluble in water. They yield only one series of salts. Oxides.—Phosphorus forms three well-defined oxides, P2O3, P2O5 and P2O7; two others, PO3 and PO4, have been described. 

Phosphorus suboxide, PO4 is said to be formed, mixed with the
PHOSPHORUS

other oxides, when the element is burnt in a limited supply of air or in pure oxygen under reduced pressure (E. Jungfleisch, Abs. Jour. Chem. Soc., 1904, 29, 279). The reaction is the same in both cases. Phosphorus in the trichloride or tribromide is exposed to light. It is a yellow or red powder which becomes dark red on heating; it is stable in air, and can be heated to 300° without decomposition. Its isolation is performed by the action of hydrated phosphoric acid, $\text{H}_3\text{PO}_4$, on trivalent phosphorus, $\text{P}_3\text{O}_{10}$, or on a mixture of meta- and pyrophosphates, with a little phosphoric acid. They react as reducing agents. Upon boiling with caustic potash they evolve hydrogen, yielding a phospine gas.

Phosphorus trichloride, $\text{PCl}_3$, obtained by Davy in 1812, may be prepared by dissolving its anhydride, $\text{PCl}_5$, in cold water; by immersing sticks of phosphorus in a solution of copper sulphate containing, in a well-closed flask, filtering, the copper sulphide solution with water, then dissolving the precipitated copper by baryta water, and concentrating the solution in vacuo; by passing chlorine into melted phosphorus covered with water, the phosphorus being then distilled into phosphorus and hydrochloric acids. It may also be prepared by leading a current of dry air into phosphorus trichloride at 60° and passing the vapours into water at 0°, the crystals thus formed being washed, washed, and dried in a vacuum. The crystals melt at 70°. The acid is very deliquescent, and oxidizes on exposure to air to phosphoric acid. It decomposes on heating into phosgene and phosphoric acid. It is an energetic reducing agent, when heated with copper sulphate solution, copper is precipitated and hydrogen evolved. Although nominally tribasic the commonest metallic salts are dibasic. Organic ethers, however, are known in which one, two and three of the hydrogen atoms are replaced by groups attached to the phosphorous atom. The metallic phosphites are stable both dry and in solution; when strongly heated they evolve hydrogen and yield a pyrophosphate, and with water they yield phosphorous acid with the evolution of phosphine gas.

Phosphorus pentachloride, $\text{PCl}_5$, obtained by Thorpe and Tuckey, by heating phosphorus trichloride, in the presence of phosphorus in vacuo, is used in the limited combustion of phosphorus in air as a sublimate of transparent, highly lustrous, orthorhombic crystals. They are highly deliquescent, and form with water a mixture of phosphorus and phosphoric acids: $\text{PO}_3\text{Cl}_3+3\text{H}_2\text{O}=\text{POCl}_3+3\text{HCl}$; the density of the vapour of phosphorus pentachloride at 102° is 2.98, slightly less than that required by $\text{P}_4\text{O}_{10}$ (West, Jour. Chem. Soc., 1902, p. 923). Phosphoric oxide, or phosphorus pentoxide, $\text{PO}_4$, formed when phosphorus is burnt in an excess of air or oxygen, or from dry phosphorus and oxygen at atmospheric pressure (Jungfleisch, loc. cit.), was examined by Boyle and named "flowers of phosphorus" by Marggraf in 1749. It is a soft, floculent powder, which on sublimation gives rise to phosphorus pentoxide and yellow fume, and deliquescent, hissing when thrown into water, with which it combines to form phosphoric acid. It is reduced when heated with carbon to phosphorus, carbon monoxide being formed simultaneously. Its decomposition into phosphorus, phosphoric acid, and phosphorus pentoxide was first demonstrated by Thomson in 1784. Oxycarbons.—Phosphorus forms several oxycarbons: hypophosphoric acid, $\text{H}_3\text{PO}_4$, and phosphoric acid, $\text{H}_3\text{PO}_4$, or $\text{H}_3\text{PO}_4$, of which the latter contains only the acid, or the corresponding acid, $\text{H}_3\text{PO}_4$; monophosphoric acid, $\text{H}_2\text{PO}_4$; phosphoric acid, $\text{H}_3\text{PO}_4$; and meta-, pyro-, and ortho-phosphoric acids, derived from $\text{PO}_3\text{O}_4$, for which see Phosphoric Acids. The normal hypophosphoric acid, $\text{H}_2\text{PO}_3\text{H}$, discovered by Dulong in 1816, and obtained crystalline by Thomson in 1874 (Ber., 7, p. 904), is prepared in the form of its barium salt by warming phosphorus with baryta water, removing the excess of baryta, and crystallizing the filtrate. The acid may be prepared by evaporating in a vacuum the solution obtained by decomposing the barium salt with the equivalent amount of sulphuric acid. The acid forms a white crystalline mass, melting at 17.4° and having a strong acid reaction. Exposure to air gives phosphorus and phosphoric acids, and on heating it gives phosphine and phosphoric acid. A mixture of phosphorus and of a red precipitate of a cuprous hydrate, $\text{Cu}_2\text{H}_2$, when heated with phosphoric acid solution, to 60°. It is a monobasic acid forming salts which are permanent in air, but which are gradually oxidized in aqueous solution. On boiling with a metallic copper solution, it forms a mixture of meta- and pyrophosphates, with a little phosphoric acid. They react as reducing agents. Upon boiling with caustic potash they evolve hydrogen, yielding a phospine gas.
acids. It does not dissociate on heating as do the pentachloride and pentabromide, thus indicating the existence of pentavalent phosphorus in a gaseous compound; dissociation, however, into the trifluoride and free fluorine may be brought about by heating. Phosphorus trifluoride, 

\[PF_3\] 

is a colourless liquid, boiling at 173° and resembling the trichloride chemically. The pentabromide, 

\[PBr_5\] 

which results from phosphorus and an excess of bromine, is a yellow solid, and closely resembles the penta-

chloehalcogenide. The compound is formed from bromine and the trichloride, into which components it decomposes at 35°. Phosphoryl bromide, 

\[PBrO_3\] 

is a solid, melting at 43° and boiling at 135°. Phosphoryl bromide, PBr_3, is volatile, as are the corresponding iodo-

the yellow octahedra which melt at 38°, and have a penetrating, aromatic odour. With water it gives sulphur, sulphurated hydrogen, and phosphorous acid being produced by the interaction of the previously formed sulphurated hydrogen and phosphoric acid. 

Phosphorus forms three iodies. The subiodide, P,I, was obtained by R. Boulough (Comptes rendus, 1905, 141, p. 256), who acted with dry iode on phosphorus dissolved in carbon disulphide; the dioxide and tri-iode are formed similarly; the first is deposited as orange-coloured prisms which melt at 110° to a red liquid (see Doughty, Journ. Amer. Chem. Soc., 1905, 27, p. 1442), whilst the second forms dark-red hexagonal plates well developed.

**Sulphides and Thio-acids.**—Phosphorus and sulphur combine energetically with considerable rise of temperature to form sulphides. The phosphorus trichloride and phosphorus trichloride, 

\[PCl_3\] 

exist in several forms: they are pungent, 

\[PCl_3\] 

giving off a strong fume when heated. The latter, on evaporation of its chlorides, gives off a pungent gas, 

\[PCl_5\] 

and is apt to polymerise, forming a solid, 

\[PCl_3\] 

in which the elementary proportions are not even. Phosphorus trichloride is a colourless liquid, boiling at 173° and having a pungent, slightly aromatic odour. It is slowly decom-

posed by water giving phosphoric and hydrochloric acids, with

**Phosphorus Compounds.**—Phosphorus pentachloride combines directly with ammonia, and the compound when heated to redness loses ammonium chloride and hydrochloric acid and gives phosphorus, 

\[PCl_3\] 

a compound first described by Davy in 1811. It is a white, insubstantial, very stable solid, which decomposes on heating, giving ammonium and metaphosphoric acid, whilst alkalis give an analogous reaction. With methyl and ethyl alcohols it forms the corresponding phosphates and phosphonates (Vigoureux, ibid., 1884, 10, p. 123). The diamide, PNH\(_2\), was obtained by Hugot (ibid., 1905, 141, p. 1235) by acting with ammonia gas on phosphorus pentachloride at 75°; it is very unstable, and decomposes at 25°. Phosphorus combines with nitrogen and chlorine to form several polymers, and the general formula (PNC\(_x\))\(_x\), where \(x\) may be 1, 2, 3, 4, 5, 6, 7, or 11; they may be obtained by heating the pentachloride in a current of nitrogen. The diamide, P(NH\(_2\))\(_2\), is decomposed by the mixture by fractional distillation (H. N. Stokes, Journ. Amer. Chem. Soc., 1898, 20, p. 740; also see Besson and Rosset, Comptes rendus, 1896, 37, p. 143). The commonest form is P(NH\(_2\))\(_3\), a crystalline solid, insoluble in water, but soluble in alcohol. The solution of it in hot water is basic in reaction, and has the properties of an amine. Several preparations of it have been described. The diamide, P(NH\(_3\))(NH\(_2\)), results when the pentachloride is saturated with ammonia gas and the first formed chlorophosphamide, PCl\(_2\)(NH\(_3\)), is decomposed by water. The triadide, PON\(_3\), results from ammonia and phosphorus pentachloride. Both these compounds on heating give phosphonomamide, PON, of which a polymer (PON\(_n\)) had been described by Oddo (Gazz. chim. Ital., 1899, 29, ii, p. 330). Stokes (Amer. Chem. Journ.,
Photius (c. 850–888), patriarch of Constantinople (867–886). From his early years he displayed an extraordinary talent and appetite for knowledge, and as soon as he had completed his education he began his literary and diplomatic work. He was deeply interested in many subjects, distinguished himself in classical literature, dialectic and philosophy. The way to public life was probably opened for him by the marriage of his brother Sergius to the princess Irene, sister of Theodora, who, upon the death of her husband Theophilus in 842, had assumed the regency of the empire. Photius became captain of the guard and subsequently first imperial secretary. The dissensions between the patriarch Ignatius and Bardas, the uncle of the youthful Emperor Michael III., brought promotion to Photius. Ignatius was arrested and imprisoned (Nov. 588), and upon refusing to resign his office was illegally deposed, while Photius, although a layman, received all the necessary sacerdotal orders within six days, and was installed as patriarch in his place. Photius, continuing to refuse the consecration which alone would give Photius's elevation a semblance of legality, was treated with extreme severity. His cause was subsequently espoused by Pope Nicholas in a manner highly offensive to the independent feeling of the Eastern Church. Photius felt himself the champion of Eastern Christianity against Latin pretensions; and when in 863 Nicholas finally anathematized and deposed him, he replied by a counter-excommunication. Meanwhile, the situation was suddenly changed by the murder of Photius's patron, Bardas, by order of the emperor Michael, who was himself assassinated by his colleague Basil in the following year (867). The fall of Photius immediately ensued; he was removed from his office and banished about the end of September 867, a few days after the accession of Basil, and Ignatius was reinstated on the 23rd of November. About 876 Photius was suddenly recalled to Constantinople and entrusted with the education of Basil's children. On the death of Ignatius, probably in October 878, Photius, after a decent show of reluctance, again filled the patriarchal throne. He then proceeded to obtain the formal recognition of the Christian world. In November 879 a synod was convened at Constantinople. The legates of Pope John VIII. attended, prepared to acknowledge Photius as legitimate patriarch, a concession for which John was compensated by Latins opinion. He stood firm, however, at the other two points which had long been contested between the Eastern and Western Churches, the ecclesiastical jurisdiction over Bulgaria and the introduction of the "filioque" clause into the creed. He disowned his legates, who had shown a tendency to yield, again excommunicated Photius, and thus aroused the open hostility which has never been appealed to this day. Strong in the support of the council, Photius simply ignored him. At the height of glory and success he was suddenly precipitated from his dignity by another palace revolution. After the death of Basil (886), his son and successor Leo, who had formerly been devoted to Photius, but in recent years displayed great hatred towards him, deprived him of his office and banished him to the monastery of St. Batholomew. From this time Photius disappears from history. No letters of this period of his life are extant, which leads to the inference that his imprisonment was severe. The precise date of his death is not known, but it is said to have occurred on the 6th of February 898.

For long after Photius's death his memory was held in no special honour by his countrymen. But when, in the crusading age, the Greek Church and state were likened in danger from Latin encroachments, Photius became a national hero, and is at present regarded as little short of a saint. To this character he has not the least pretension. Few men, it is probable, have been more atrociously calumniated and scourged out, with as little justice as he. But when his case has been rejected, he still appears on a general review of his actions worldly, crafty and unscrupulous. Yet he shows to no little advantage as an ecclesiastical statesman. His firmness and sagacity are marked even in his more unguarded and false judgments; he supported good and evil fortune with equal dignity; and his fall was on both occasions due to revolutions beyond his control. In erudition, literary power, and force and versatility of intellect he far surpassed every contemporary.

The most important of the works of Photius is his renowned Bibliotheca or Myriobiblon (ed. I. Bekker, 1824–1825), a collection of extracts from and abridgments of 260 volumes of classical authors (usually cited as Codices), the originals of which are now to a great extent lost. The work is specially rich in extracts from historical writers. To Photius we are indebted for almost all we possess of works we have lost. He is also the chief source of information on the lost writings of Arrian. Theology and ecclesiastical history are also very fully represented, but poetry and ancient philosophy are almost entirely ignored. It seems that he did not think it necessary to deal with those authors with whom every well-educated man would naturally be familiar. The literary criticisms, generally distinguished by keen and independent judgment, and the excerpts, vary considerably in length. The numerous biographical notices are often taken from the life of Miletus, the Lexicon (Μελετον Σωφρονιτη), published later than the Bibliotheca, was probably in the main the work of some of his pupils. It was intended as a book of reference to facilitate the reading of the works of Greek authors, whose names and vocabulary were out of date. The only MS. of the Lexicon is the Codex Galenus, formerly in the possession of Thomas Gale (q.v.), and now in the library of Trinity College, Cambridge (ed. S. A. Naber, 1864, 1868), the text of the Greek edition is most valuable. The most important theological work is the Amphitheatra, a collection of some 300 questions and answers on difficult points in Scripture, addressed to Amphileichus, archbishop of Cyprus (ed. Sophocles Oeconomus, Athens, 1829). Other similar works are his treatise in four books
PHOTOCHEMISTRY

against the Manicheans and Paulicians, and his controversy with the Latins on the Procession of the Holy Spirit. His Epistles, political and private, addressed to high church and state dignitaries, and his theological works show that they have lighted up the charism and versatility of the writer (ed. J. Valletta, London, 1864). A large number of his speeches and homilies have been edited by S. Aristarchos (1900). The only complete edition is Bishop Malou’s in Migne’s Patrologia Graeca, c. 877, vol. cxv, p. 173. Reiffenstein (Der Aufstand des Lexikons, 1907) has published a hitherto unedited MS, containing numerous fragments from various verse and prose authors.

After the allusions in his own writings the chief contemporary authority for the life of Photius is his bitter enemy, Nicetas the Phokas, the biographer of his rival Ignatius. The standard modern work is the study of Cardinal Hergenröhder, Photos, Würzburg, 1880. It contains fragments from an old manuscript (1567-1868). As a dignitary of the Roman Catholic Church, Cardinal Hergenröhder is inevitably biased against Photius as an ecclesiast, but his natural candour and sympathy with intellectual eminence have made him just to the man.

Fabricius, Bibliotheca græca, x. 670-776, xi. 1-37; C. Krummacher, Geschichte der byzantinischen Literatur, pp. 73-79, 515-524 (2nd ed., 1897); J. E. Sandys, History of Classical Scholarship (2nd ed., 1906).

PHOTOCHROMY (Gr. φως, light, and “chemistry”), in the widest sense, the branch of chemical science which deals with the physical properties of substances and their reactions to light, or rather the narrower sense it is concerned with the action of light on chemical change. The first definition includes such subjects as refractive and dispersive power, colour, fluorescence, phosphorescence, optical isomerism, spectroscopy, &c.—subjects which are treated under other headings; here we only discuss the subject matter of the narrower definition.

Probably the earliest photochemical investigations were associated with the darkening of certain silver salts under the action of light, processes which were subsequently utilized in photography (q.v.). At the same time, however, it had been observed that other chemical changes were regulated by the action of light. The first complete study of such a problem was made by J. W. Draper in 1843, who investigated the combination of hydrogen and chlorine to form hydrochloric acid, a reaction which had been previously studied by Gay-Lussac and Thénard. Draper concluded that the first action of sunlight consisted in producing an allotrope of chlorine, which subsequently combined with the hydrogen. This was denied by Bunsen and Roscoe in 1857; and in 1887 Pringsheim suggested that the reaction proceeded in two stages: $\text{H}_2\text{O} + \text{Cl}_2 = \text{Cl}_2\text{O} + \text{H}_2$; $\text{H}_2 + \text{Cl}_2\text{O} = \text{H}_2\text{O} + 2\text{Cl}$. This view demands the presence of water vapour (H. B. Baker showed that the perfectly dry gases would not combine), and also that the chlorine might have been formed by the reaction here mentioned (the “photochemical induction” of Bunsen and Roscoe) as taken up by the formation of the chlorine monoxide necessary to the second part of the reaction.

The decomposition of hydriodic acid into hydrogen and iodine was studied by Lemoine in 1877, who found that 80% decomposed after a month’s exposure; he also observed that the reaction proceeded quicker in blue vessels than in red. A broader investigation was published by P. L. Chaidsach in 1878, who found that the red rays generally oxidized inorganic compounds, whilst the violet reduced them, and that with organic compounds the action was entirely oxidizing. These and other reactions suggested the possibility of utilizing them for measuring the actinic effect of light waves. The most important employ silver salts; Eder developed a form based on the reaction between mercuric chloride and ammonium oxalate: $2\text{HgCl}_2 + \text{(NH}_4\text{)}_2\text{C}_2\text{O}_4 = 2\text{HCl} + 2\text{NH}_4\text{Cl} + 2\text{CO}_2$, the extent of the decomposition being determined by the amounts of mercuric chloride or carbon dioxide liberated.

The article PHOTOGRAPHY (q.v.) deals with early investigations on the chemical action of light, and we may proceed here to modern work on organic compounds. That sunlight accelerates the action of the halogens, chlorine and bromine, on such compounds, is well known. John Davy obtained phosphene, COCl, by the direct combination of chlorine and carbon monoxyde in sunlight (see Weigert, Ann. d. Phys., 1907 iv., 24, p. 557); chlorine combines with half its volume of methane explosively in sunlight, whilst in diffused light it substitutes; with toluene it gives benzyl chloride, C\text{H}_3\text{C\text{H}}_2\text{Cl}, in sunlight, and chlortoluene, C\text{H}_3\text{(CH}_2\text{)}_2\text{Cl}, in the dark; with benzene it gives an addition product, C\text{H}_3\text{C\text{H}}_2\text{Cl}, in sunlight, and substitutes in the dark. Bromine deports itself similarly, substituting and forming addition products with unsaturated compounds more readily in sunlight. Sometimes isomerization may occur; for instance, a diacetic and the first isomerize in the dark, and dibromtiglic acid in sunlight. Many substances decompose when exposed to sunlight; for example, alkyl iodides darken, owing to the liberation of iodine; aliphatic acids (especially dibasic) in the presence of uronic oxide lose carbon dioxide; polyhydric alcohols give products identical with those produced by fermentation; whilst aliphatic ketones give a hydrocarbon and an acid.

Among aromatic compounds, benzoaldehyde gives a trimeric and tetrameric benzoaldehyde, benzoic acid and hydrobenzoin (G. L. Ciancian and P. Silber, Atti. R. Accad. Lincei, 1900); in alcoholic solution it gives hydrobenzoin; whilst with nitro-compounds, the hydrobenzoin suffering reduction to nitrosobenzene and phenyl-β-hydroxylamine; the latter isomerizes to ortho- and para-aminophenol, which, in turn, combine with the previously formed benzoic acid. Similary acetophenone and benzophenone in alcoholic solution give dimethylhydrobenzoin and benzoinacne. With nitro compounds Sach and Hillberg concluded that those containing a CH- side group in the ortho position to the NO group were decomposed by light. For example, ortho-nitrobenzaldehyde in alcoholic solution gives nitrosobenzene ester and 22' azoxybenzoic acid, with the intermediate formation of nitrobenezaldehydethiylacetal, NO$_2$\text{CH}_2\text{CH(OC\text{H}_3)}_2$ (E. Bamberger and F. Elger, Ann. 1910, 371, p. 316). Bamberger also investigated nitrosobenzene, obtaining azoxybenzene as chief product, together with various azo compounds, nitrosoaniline, aniline, hydroquinone and a resin.

For the photochemistry of diazo derivatives see Ruff and Stein, Ber., 1901, 34, p. 1668, and of the terpenes see G. L. Ciancian and P. Silber, Ber., 1907 and 1908.

Light is also powerful in producing isomerization and polymerization. Isomerization chiefly appears in the formation of stable stereo-isomers from the labile forms, and more rarely in inducing real isomerization or phototropy (Markwald, 1890). As examples we may notice the observation of Chattaway (Journ. Chem. Soc. 1906, 86, p. 462) that many phenylhydrzones (yellow) change into azo compounds (red), of M. Padoa and F. Elgar, Ann. 1910, 371, p. 316; Tietze and Bamberger, based on the β-naphthylhydrzones (the α-compounds are not phototropic), and of A. Senier and F. G. Shephard (Journ. Chem. Soc., 1906, 95, p. 1493) on the aryldiene- and naphthylidene-amines, which change from yellow to orange on exposure to sunlight. Light need not act in the same direction as heat (changes due to heat may be termed thermotropic). For example, heat changes the α form of benzyl-β-aminoacryonic ester into the β form, whereas light reverses this; similarly heat and light have reverse actions with α-sis-diphenyl ethylene, C\text{H}_2\text{C}(\text{C}_6\text{H}_5\text{)}C\text{H}_2\text{Cl} (R. Stoeerner, Ber., 1909, 42, p. 4863); the change, however, is in the same direction with Senier and Shephard’s compounds. With regard to polymerization, we may notice the production of benzene derivatives from acetylene and iodine, and homologues, and of tetramethylenes from the olefins.

Theory of Photocatalytic Action.—Although much work has been done in the qualitative and quantitative study of photochemical reactions relatively little attention has been given to the theoretical explanation of these phenomena. That the solution was to be found in an analogy to electrolysis was suggested by Grotthuss in 1818, who laid down: (1) only those rays which are absorbed can produce chemical change, (2) the action of the light is analogous to that of a voltaic cell; and he regarded light as made up of positive and negative electricity. The first principle received early acceptance; but the development of the second is due to W. D. Bancroft who, in a series of
papers in the *Journal of Physical Chemistry* for 1908 and 1909, has applied it generally to the reactions under consideration. Any electrotyic action demands a certain minimum electromotive force; this, however, can be diminished by suitable depolarizers, which generally act by combining with a product of the decomposition. Similarly, in some photochemical reactions the low electromotive force of the light is sufficient to induce decomposition, but in other cases a depolarizer must be present. For example, ferric chloride in aqueous solution is unchanged by light, but in alcoholic solution reduction to ferrous chloride occurs, the liberated chlorine combining with the alcohol. In the same way Bancroft showed that the solvent media employed in photographic plates act as depolarizers. The same theory explains the action of sensitizers, which may act optically or chemically. In the first case they are substances having selective absorption, and hence alter the sensitivity of the system to certain products. In the second case there are no strong absorption bands, and the substances act by combining with the decomposition products. Bancroft applied his theory to the explanation of photochemical oxidation, and also to the chlorination and bromination of hydrocarbons. In the latter cases he supposed that the halogen produces ions only if the ions are in excess side chains are substituted, if the negative the nucleus.

**PHOTOGRAPHY** (Gr. φῶς, light, and γράφειν, to write), the science and art of producing pictures by the action of light on chemically prepared (sensitized) papers or films.

**History.**

It would be somewhat difficult to fix a date when we now know as "photographic action" was first recorded. No doubt the tanning of the skin by the sun's rays was what was first noticed, and this is as truly the effect of solar radiation as is the darkening of the sensitive paper which is now in use in photographic printing operations. We may take it that K. W. Scheele was the first to investigate the darkening action of sunlight on silver chloride. He found that when silver chloride was exposed to the action of light beneath water there was dissolved in the fluid a substance which, on the addition of lunar caustic (silver nitrate), caused the precipitation of new silver chloride, and that on applying a solution of ammonia to the blackened chloride an insoluble residue of metallic silver was left behind. He also noticed that of the rays of the spectrum the violet most readily blackened the silver chloride. In Scheele, then, we have the first who applied combined chemical and spectrum analysis to the science of photography. In 1782 J. Senebier repeated Scheele's experiments, and found that in fifteen seconds the violet rays blackened silver chloride as much as the red rays did in twenty minutes. 1 In 1787 Count Rumford contributed a paper to the *Philosophical Transactions* entitled "An inquiry concerning the chemical properties that have been attributed to light," in which he tried to demonstrate that all effects produced on metallic solution could be brought about by a temperature somewhat less than that of boiling water. Robert Harrup in 1802, however, conclusively showed in *Nicholson's Journal* that, at all events, salts of mercury were reduced by visible radiation and not by change of temperature.

In 1801 we come to the next decided step in the study of photographic action, when Johann Wilhelm Ritter (1776-1810) proved the existence of a portion of the violet rays invisible to the human eye, and found that they had the power of blackening silver chloride. Such a discovery naturally gave a direction to the investigations of others, and Thomas Johann Seebeck (1770-1831) (between 1802 and 1808) and, in 1812, Jacques Étienne Béard (1789-1869) turned their attention to this particular subject, eliciting valuable information. We need only mention two or three other cases where the influence of light was noticed at the beginning of the 19th century. William Hyde Wollaston observed the conversion of yellow gum guaiacum into a green tint by the violet rays, and the restoration of the colour by the red rays—both of which are the effect of absorption of light, the original yellow colour of the gum absorbing the violet rays, whilst the green colour to which it is changed absorbs the red rays. Sir Humphry Davy found that puce-coloured lead oxide, when damp, became red in the red rays, whilst it blackened in the violet rays, and that the green mercury oxide became red in the red rays—again an example of the necessity of absorption to effect a molecular or chemical change in a substance. U. R. T. Le Bouvier Desmorties in 1801 observed the change effected in Prussian blue, and Carl Wilhelm Bückner noted the action of the two ends of the spectrum on phosphorus, a research which John William Draper extended farther in America at a later date.

To England belongs the honour of first producing a photograph by utilizing Scheele's observations on silver chloride. In June 1802 Thomas Wedgwood (1771-1805) published in the *Journal of the Royal Institution* the paper—"An account of a method of copying paintings upon glass and of making profiles by the action of light upon it; with the process of printing of such profiles by H. Davy." He remarks that white paper or white leather moistened with a solution of silver nitrate undergoes no change when kept in a dark place, but on being exposed to the daylight it speedily changes colour, and, after passing through various shades of grey and brown, becomes at length nearly black. The alteration of colour takes place more speedily in proportion as the light is more intense.

"In the direct beam of the sun two or three minutes are sufficient to produce a full effect, but several hours are required, and light transmitted through different-coloured glasses acts upon it with different degrees of intensity. Thus it is found that red rays, or the common sunbeams passed through red glass, have very little effect upon it; yellow and green are more efficacious, but blue and violet light produce the most decided and powerful effects." 2

Wedgwood goes on to describe the method of using this prepared paper by throwing shadows on it, and inferentially by what we now call "contact printing." He states that he has been unable to fix his prints, no washing being sufficient to eliminate the traces of the silver salt which occupied the unexposed or shaded portions. Davy in a note states that he has found that, though the images formed by an ordinary camera obscura were too faint to print out in the solar microscope, the images of small objects could easily be copied on such paper.

"In comparing the effects produced by light upon muriate of silver (silver chloride) with those upon the different-coloured glasses acts upon it with different degrees of intensity. Thus it is found that red rays, or the common sunbeams passed through red glass, have very little effect upon it; yellow and green are more efficacious, but blue and violet light produce the most decided and powerful effects." 3

PHOTOGRAPHY

the brown band, . . . which was produced in the violet, the silver chloride was coloured a grey-violet for a distance of several inches. In proportion as the distance from the violet increased, the tint became lighter. Beyond the red, on the contrary, the chloride took a feeble red tint for a considerable distance. When moist chloride of silver, having received the action of light for a time, is exposed to the spectrum, the blue and violet behave as above. In the yellow and red regions, and the other hand, it is found that the silver chloride becomes paler: . . . the parts acted upon by the red rays and those beyond take a light coloration."

This has been advanced by J. M. Eder as being the first record we have of photographic action lending itself to production of natural colours. This observation of Seebeck was allowed to lie fallow for many years, until it was again taken up and published as a method.

The first to found a process of photography which gave pictures that were subsequently unaffected by light was Niepce de Niepce. His process, which he called provisionally "héliographie, dessins, et gravures," consists in coating the surface of a metallic plate with a solution of asphaltum in oil of lavender and exposing it to a camera image. He recommends that the asphaltum be powdered and the oil of lavender dropped upon it in a wine-glass, and that it be then gently heated. A polished plate is covered with this varnish, and, when dried, is ready for employment in the camera. After requisite exposure, which is very long indeed, a very faint image remains on the metal; and development by an employment of the asphaltum in a solution of bitumen of lampblack with ten parts by volume of white petroleum. After this mixture has been allowed to stand two or three days it becomes clear and is ready to be used. The plate is placed in a dish and covered with the solvent. By degrees the parts unaffected by light dissolve away, and the picture, formed of modified asphaltum, is developed. The plate is then lifted from the dish, allowed to drain, and finally freed from the remaining solvents by washing in water. Subsequently, instead of using oil of lavender as the asphaltum solvent, Niepce employed an animal oil, which gave a deeper colour and more tenacity to the surface-film.

Later, Louis Jacques Mandé Daguerre (1789-1851) and Niepce used as a solvent the brittle residue obtained from evaporating the oil of lavender dissolved in ether or alcohol—a transparent solution of a lemon-yellow colour being formed. This solution was used for covering glass or silver plates, which, when dried, could be used in the camera. The time of exposure varied somewhat in length. Daguerre remarked that "the time required to procure a photographic copy of a landscape is from seven to eight hours, but single monuments, when strongly lighted by the sun, or which are themselves very bright, can be taken in about three hours." Perhaps there is no sentence that indicates more forcibly the advance made in photography from the days when this process was described. The ratio of three hours to 1/4th of a second is a fair estimate of the progress made since Niepce. The development was conducted by means of petroleum-vapour, which dissolved the parts not acted upon by light. As a rule silver plates seem to have been used, and occasionally glass; but it does not appear whether the latter material was chosen because an image would be projected through it or whether simply for the sake of effect. Viewed in the light of present knowledge, a more perfectly developable image in half-tone would be obtained by exposing the film through the back of the glass. The action of light on most organic matter is apparently one of oxidation. In the case of asphaltum or bitumen of Jaudia the oxidation causes a hardening of the material and an insolubility in the usual solvents. Hence that surface of the film is generally hardened first which first feels the influence of light. Where half-tones exist, as in a landscape picture, the film remote from the surface first receiving the image is not acted upon at all, and remains soluble in the solvent. It is thus readily seen that, in the case of half-tone pictures, or even in copying engravings, if the action were not continued sufficiently long when the surface of the film farthest from the glass was first acted upon, the layer next the glass would in some places remain soluble, and on development would be dissolved away, carrying the top layer of hardened resins matter with it, and thus give rise to imperfect pictures. In carbon-printing development from the back of the exposed film is absolutely essential, since it depends on the same principles as does heliography, and in this the same mode of procedure is advisable.

It would appear that Niepce began his researches as early as 1814, but it was not till 1827 that he had any success worth recounting. This was at a date before Dr. Talbot, named the secretary of the Royal Society of London, with a view to its presentation to that society. Its publication, however, was prevented because the process of which examples were shown, was a daguerrotype. In an authentic MS. copy of Niepce's "Mémoire" dated "Kew, le 8 December 1827," he says that "in his framed drawings made on tin the tone is too feeble, but that by the use of chemical agents the tone may be darkened." This shows that Niepce was familiar with the employment of tin for darkening medium even with his photographs taken on tin plates.

Daguerrotype. We have noticed in the joint process of Daguerre and Niepce that polished silver plates were used, and we know from the latter that amongst the chemical agents tried iodine suggested itself. Iodine vapour or solution applied to a silvered plate would cause the formation of silver iodide on those parts not acted upon by light. The removal of the resinosus picture would leave an image formed of metallic silver, whilst the black parts of the original would be represented by the darker image developed by the light on the plate. This is the daguerrotype process. Such observers as Niepce and Daguerre, who had formed a partnership for prosecuting their researches, would not have thus formed silver iodide without noticing that it changed in colour when exposed to the light. What parts respectively Daguerre and Niepce played in the development of the daguerrotype will probably never be known with absolute accuracy, but in a letter from Dr. Bauer to Dr. J. J. Bennett, F.R.S., dated the 7th of May 1830, the former says:—

"I received a very interesting letter from Mons. Isidore Niepce, dated 12th March [about a month after the publication of the daguerrotype process], and that letter falsly confirms what I suspected of Daguerre's manoeuvres with poor Niephe, but Mr. Isidore observes that for the present that letter might be considered confidential."

Dr. Bauer evidently knew more of "poor Niepche's" work than most people, and at that early period he clearly thought that an injustice had been done to Niepce at the hands of Daguerre. It should be remarked that Niepche de Niepce died in 1833, and a new agreement was entered into between his son Isidore de Niepce and Daguerre to continue the prosecution of their researches. It appears further that Niepce communicated his process to Daguerre on the 5th of December 1829. At his death some letters from Daguerre and others were left by him in which iodine, sulphur, phosphorus, &c., are mentioned as having been used on the metal plates, and their sensitiveness to light, when thus treated, commented upon. We are thus led to believe that a great part of the success in producing the daguerrotype is due to the elder Niepce; and indeed it must have been thought so at the time, since, on the publication of the process, life-pensions of 6000 francs and 4000 francs were given to Daguerre and to Isidore Niepce respectively. In point of chronology the publication of the discovery of the daguerrotype process was made subsequently to the Talbot-type process. It will, however, be convenient to continue the history of the daguerrotype, premising that it was published on the 6th of February 1839, whilst Talbot's process was given to the world on the 25th of January of the same year.

Daguerrotype pictures were originally taken on silver-plated copper, and even now the silvered surface thus prepared serves as the base for the electro-plating of the metal plates, on which the image is formed. The process is as follows. A brightly-polished silver plate is cleaned by finely-powdered pumice and olive oil, and then by dilute nitric acid, and finally washed in emulsion. When a brilliant white coating of foreign matter or stain is being fastened to the production of a perfect picture. The plate, thus prepared, is ready for the iodizing operation. Small fragments of iodine are used, which are placed over a silvered plate. When a gauze is placed, face downwards, resting on supports, and the vapour from the iodine is allowed to form upon it a surface of silver iodide. It is essential to note the colour of the surface-formed iodide at several stages, the varying colours being due to interference colours.
caused by the different thicknesses of the minutely thin film of iodide. The stage of maximum sensitiveness is obtained when it is of a golden orange colour. In this state the plate is withdrawn and washed. The image of the camera, ready for exposure. A plan frequently adopted to give an even film of iodide or to saturate a card with iodine and hold the plate a short distance above the card. Long exposures were required, varying in Paris from three to seven days. The greater part of it could, in the second or two months following, lose sensibility to light by being exposed to the air, or by brushing and rubbing. What sensibility it still possessed was due to the exposure of the image by mercury vapour is said to be due to a chance discovery of Daguerre. It appears that for some time previous to the publication of the daguerreotype method he had been experimenting with plates covered by a layer of silver chloride and iodine and that it was by brushing the surface of the image that mercury vaporization was called the "printing out process. This operation involved so long an exposure that he sought some means of reducing it by the process of exhaustion he arrived at the fact that it was the mercury vapour, which even at ordinary temperatures volatilizes, that had caused this intensification of the almost invisible camera-image. It was this discovery that enabled the exposures to be very considerably shortened to those which it was found necessary to give in mere camera-printing.

The development of the image was effected by placing the exposed plate over a slightly heated (about 75° C.) cup of mercury. The variation in the temperature of the cup was found that the action of the mercury on the image was in an almost exact ratio to the intensity of its action. This produced a picture in an amalgam, the vapour of which attached itself to the image. So that Reade described as a new process. This was subsequently afforded by the fact that the mercurial image could be removed by heat. The developing box was so constructed that it was possible to examine the picture through a yellow glass window whilst the image was being brought out. The next operation was to fix the picture by dipping it in a solution of hyposulphite of soda. The image produced by this method is so delicate that it will not bear the slightest handling, and has to be protected from accidental touching.

The first great improvement in the daguerreotype process was the sensitizing of the iodized film by bromine vapour. For this purpose a Brotherick Goddard published his account of the use of bromine in conjunction with iodine in 1840, and A. F. J. Claudet (1797-1867) employed a combination of iodine and chlorine vapour in 1841. In 1844 Daguerre published his improved method of preparing the plates, which is in reality based on the use of bromine with iodine. That this addition points to additional sensitiveness will be readily understood when we remark that so-called instantaneous pictures of yachts in full sail, and of large size, have been taken on plates so prepared—a feat which is utterly impossible with the original process as described by Daguerre. The next improvement in the process was toning or grading the image by a solution of gold, a practice introduced by Sir W. Grove. Gold chloride is mixed with hypochlorite of soda, and the levellled plate, bearing a sufficient quantity of the fluid, is warmed by a spirit-lamp until the required vigour is given to the image, as a consequence of which it is better seen in most lights. Nearly all the daguerreotypes extant have been treated in this manner, and no doubt their permanence is in a great measure due to this operation. Images of this class can be copied by taking electrotypes from them, as shown by Sir W. R. Grove and others. These reproductions are admirable in every way, and furnish a proof that the daguerrean image is a relief.

Fox-Talbot Process.—In January 1839 Fox Talbot described the first of his processes, photogenic drawing, in a paper to the Kitchener Society. The length of the exposure was evidently a great advantage. It was being experimented in 1834, and that in the solar microscope he obtained an outline of the object to be depicted in full sunshine in half a second. He published in the Philosophical Magazine full details of his method, which consisted essentially in soaking paper in common salt, brushing one side only of it with about a 12% solution of silver nitrate in water, and drying at the fire. Fox Talbot stated that by repeating the alternate washes of the silver and salt—always ending, however, with the former—greater sensitiveness was attained. This is the same in every respect as the method practised by Wedgwood in 1802; but, when we come to the next process, which he called "calotype" or "beautiful picture," we have a distinct advance. This process Talbot protected by a patent in 1841. It may be briefly described as the application of silver iodide to a paper support. Carefully selected paper was brushed over with a solution of silver nitrate (100 grains to the ounce of distilled water), and when the paper was dry the image was sensitized by holding it for a moment in a solution of potassium iodide (500 grains being dissolved in a pint of water), where it was allowed to stay two or three minutes until silver iodide was formed. In this state the iodide is scarcely sensitive to light, but it is found that when the rate of evaporation is very slow or to which the silver nitrate had been first applied. This "gallonitrate" is merely a mixture, consisting of 100 grains of silver nitrate dissolved in 2 oz. of water, to which is added one-sixth of its volume of solution of gallic acid in water, and one min of a saturated solution of gallic acid in water. The prepared surface is then ready for exposure in the camera, and, after a short insolation, develops itself in the dark, or the development may be continued in the solution of the "gallonitrate of silver." The picture is then fixed by washing it in clean water and drying slightly in blotting paper, after which it is treated with a solution of potassium bromide, and again washed and dried. Here there is no mention of a hypochlorous acid as a fixing agent, that having been first used by Sir J. Herschel in February 1840.

In a strictly historical notice it ought be mentioned that deposits of silver nitrate and silver nitrate was first known to Rev. J. Reade. When impressing images in the solar microscope he employed gallic acid and silver nitrate in order to render more sensitive the silver chloride paper that he was using, and he never has been able to prove that this could be done without the aid of light. The priority of the discovery was claimed by Fox Talbot; and his claim was sustained after a lawsuit, apparently on the ground that he had been the first to use gallic acid and silver nitrate. Fox Talbot afterwards made many slight improvements in the process. In one of his patents he recognizes the value of the proper fixing of his photogenic drawings by hypochlorous of soda, and also the production of positive prints from the calotype negatives. We pass over his application of albumen to porcelain and its subsequent treatment with iodine vapour, as also his application of albumen in which silver iodide was held in suspension to a glass plate, since in this he was preceded by Niepce de St Victor in 1848.

Albumen Process on Glass.—It was a decided advance when Niepce de St Victor, a nephew of Niepce de Niepce, employed platinum chloride and silver nitrate. In 1848, 1849, and 1850, the method of this did not meet with much success. In the hands of Blanquat Évrard it became more practicable; but it was carried out in its greatest perfection by G. Le Gray.

The outline of the operations is as follows: The whites of five fresh eggs are mixed with about one hundred grains of potassium iodide, about twenty grains of potassium bromide and ten grains of common salt. The mixture is beaten up into a froth and allowed to stand for five minutes, and then the clear froth removed. A circular pool of albumen is poured on a glass plate, and a straight ruler (its ends being wrapped with waxed paper to prevent its edge from touching the plate) divided the plate into two equal halves. Each is drawn over the plate, sweeping off the excess of albumen, and so leaving an even film. The plate is first allowed to dry spontaneously, a final heating being given to it in an oven or before the fire. The heat hastens the fixing of the albumen and it becomes insoluble and ready for the silver nitrate bath. One of the difficulties is to prevent crystallization of the salts held in solution, and this can only be effected by keeping them in defect rather than in excess. The plate is sensitized for five minutes in a bath of silver nitrate, acetylated with acetic acid, and exposed whilst still wet, or it may be slightly washed and again dried and exposed whilst in its desiccated state. The image is developed by gallic acid in the usual way.

After the application of albumen many modifications were introduced in the shape of starch, serum of milk, gelatin, all of which were intended to hold iodide in situ on the plate; and the development in every case seems to have been by gallic acid. At one time the waxed-paper process subsequently introduced by Talbot was a great favourite, although what was done was a great originality. It was shown that a photographic emulsion of fine translucent by white wax was immered in a solution of potassium iodide until immersed with it, after which it was sensitized in the usual way, development being by gallic acid. In images obtained by this process the high lights are represented by metallic silver, whilst the shadows are translucent. Such a print is called a "negative." When silver chloride paper is darkened by the passage of light through a negative, we get the highest lights represented by white paper and the shadows by darkened chloride. A print of this kind is called a "positive."
PHOTOGRAPHY

[History]

in 1850, on the introduction of collodion (q.v.), a very convenient vehicle on account of the facility with which the plates are prepared, and also because it is a substance as a vehicle for fixing and developing unaffected by silver nitrate, which is not the case with other gelatinous substances. Thus albumen forms a definite silver compound, as do gelatin, starch and gum. The employment of collodion was first suggested by Le Gray, but it remained for Frederick Scott Archer of London, closely followed by P. W. Fry, to make a really practical use of the discovery. When collodion is poured on a glass plate it leaves on drying a hard transparent film which under the microscope is slightly reticulated. Before drying, the film is gelatinous and perfectly adapted for holding in situ salts soluble in ether and alcohol. Where such salts are present they crystallize out when the film is dry, and such a film is only suitable where the plates are ready to be immersed in the silver bath. As a rule, about five grains of the soluble gum-cotton are dissolved in an ounce of a mixture of equal parts of ether and alcohol, both of which must be of low specific gravity, 0.725 and 0.805 respectively. If the alcohol or ether be much diluted with water the gum-cotton (pyroxylin) precipitates, but, even if less diluted, it forms a film which is "crepey" and uneven. Such was the material which Le Gray proposed and which Archer brought into practical use. The opaque silver plate with its one impression was abandoned; and the paper support of Talbot, with its inequalities of grain and thickness, followed suit, though it lives on in a refined form. It once a negative, it was taken with collodion on a glass plate—the image showing high lights by almost complete opacity and the shadows by transparency (as was the case, too, in the calotype process)—any number of impressions could be obtained by means of the silver-printing process introduced by Fox Talbot, and they were found to possess a delicacy and refinement of detail that certainly eclipsed the finest obtained by that certain negative. To any one who had practised the somewhat tedious calotype process, or the waxed-paper process of Le Gray with its still longer preparation and development, the advent of the collodion method must have been extremely welcome, since it enabled one to work without exactness and without a guide. The rapidity of photographic action was much increased, and the production of a different character of pictures thus became possible.

We give an outline of the procedure. A glass plate is carefully cleaned by a detergent such as a cream of tripoli powder and spirits of wine (to which a little ammonia is often added), then wiped with a soft rag, and finally polished with a silk handkerchief or chamois leather. The surface is obtained containing some moisture, and must be allowed to flow over the plate, all excess being drained off when it is covered. A good standard formula for the collodion is—55 grains of pyroxylin, 5 oz. of alcohol, 5 oz. of ether; and in this liquid are dissolved 23 grains of ammonia chloride, 2 grains of acetic acid, and mixture of cadmium bromide. When the collodion is set the plate is immersed in a bath of silver nitrate—a vertical form being that mostly used in England, whilst a horizontal dish is used on the continent of Europe—a good formula for which is 200 grains of silver nitrate with 10 oz. of water. The plate is steadily lowered into this solution, and moved in it until all the repellent action between the aqueous solution of the silver and the solvents of the collodion is removed, then it is allowed to rest for a couple of minutes, after which period it is taken out and placed in the dark slide ready for exposure in the camera. After undergoing proper exposure the plate is removed from the light, and it is then covered with a flow light solution applied, which originally was a solution of pyrogallic acid in water restrained in its action by the addition of acetic acid. One of the commonest formulae employed by P. H. Delamotte was 9 grains of pyrogallic acid, 2 drachms of glacial acetic acid and 3 oz. of water. The image gradually appears after the application of this solution, building itself up from the silver nitrate clinging to the film, which is reduced to the metallic state by degrees. Should the development be stopped at this stage a few drops of hydrochloric acid to the pyrogallic acid solution and the developing action continued.

In 1854 Robert Hunt introduced another reducing agent, which is still the favourite, viz. ferrous sulphate. By its use the time of development was reduced and the image developed with great rapidity. A sample of this developing solution is 20 grains of ferrous sulphate, 20 minims of acetic acid, with 1 oz. of water. This formula enables the impression to be developed in the formation of a good print, and it is intensified with pyrogallic acid and silver. Other intensifiers are used to increase the density on a plate by means of mercury or uranium, followed by other solutions to still further darken the double salts formed on the film.

Such intensifying agents have to be applied to the image after the plate is fixed, which is done by a concentrated solution of hypo-sulphite of soda or by potassium cyanide, the latter salt having been first introduced by Marc Antoine Augustin Gaudin in 1853 (Le Lumiere, April 23, 1853). Twenty-five grains of potassium cyanide to one ounce of water is the strength of the solution usually employed. The reaction of both of these fixing agents is to form with the sensitive salts of silver double hypo-sulphites or cyanides, which are soluble in water and salt. The utility of bromides in the collodion process seems to have been recognized in its earliest days, Scott Archer (1852) and R. J. Bingham (1850) both mentioning it. We understand his process as late as 1866 a patent-right in its use was sought to be enforced in America, the patent being taken out by James Cutting in July 1854.

Positive Pictures by the Collodion Process.—In the infancy of the collodion process it was shown by Horne that a negative image could be made to assume the appearance of a positive by whitening the metallic silver deposit. This he effected by using with the pyrogallic acid developer a small quantity of nitric acid. A better result was obtained by P. W. Fry with ferrous sulphate and ferrous nitrate, whilst Hugh Diamond gave effect to the matter in a practical way. F. Scott Archer used mercuric chloride to whiten the image. To Robert Hunt, however, must be credited the credit of noticing the action of silver nitrate in this respect; and in 1854 it was shown that the image may be made to stand out against black velvet, or black varnish may be poured over the film to give the necessary black background, or, more recently, the positive pictures may be produced on japanned iron plates (ferrotype plates) or on japanned leather. This process is still occasionally practised by itinerant photographers.

Moist Collodion Process.—It is seen that for the successful working of the collodion process it was necessary that the plate should be exposed very shortly after its preparation; this was a drawback, inasmuch as it necessitated taking a heavy equipment into the field. In 1856, Sir William Crookes and J. Spiller published in the Philosophical Magazine a process whereby they were enabled to keep a film moist (so as to prevent crystallization of the silver nitrate) several days, enabling plates to be prepared at home, exposed in the field, and then developed in the dark room. The plate was prepared in the usual way and a solution of zinc nitrate and silver nitrate in water was made to flow over it. The hygroscopic nature of the zinc salt kept sufficient moisture on the plate to attain the desired end. Various modifications in procedure have been made.

Dry Plates.—It would appear that the first experiments with collodion dry plates were due to Marc Antoine Augustin Gaudin. In La Lumiere of the 22nd of April and the 27th of May 1854 he proposed, as his reason for the question of 1853 that G. R. Muirhead published on the 4th of August 1854, that light acts almost as energetically on a dry surface as on a wet after all the silver has been washed away from the former previous to desiccation. J. M. Taupenot, however, seems to have been the first to use a dry-plate process that was really workable. His original plan was to coat a plate with collodion, sensitize it in the ordinary manner, wash it, cause a solution of albumen to flow over the surface, dry it, dip it in a bath of silver nitrate acidified with acetic acid, and wash and dry it again. The plate was then in a condition to be exposed, and was to be developed with pyrogallic acid and silver. In this method we have the same manipulation, which is long in execution, though perfectly effective.

A great advance was made in all dry-plate processes by the introduction of what is known as the "alkaline developer," which is, however, inapplicable to all plates on which silver nitrate is present in the free state. The developers previously described, either for collodion or paper processes, were dependent on the reduction of metallic silver by some such agent as ferrous sulphate, the reduction taking place gradually and the reduced particles aggregating on those portions of the film which had been acted upon by light. The action of light being to reduce the silver iodide, bromide or chloride, these reduced particles really acted as nuclei for the crystallized metal. It will be evident that in such a method of development the molecular attraction
acts at distances relatively great compared with the diameters of the molecules themselves. If it were possible to reduce the altered particles of silver salt it was plain that development would be more rapid, and also that the number of molecules reduced by light would be smaller if the metallic silver could be derived from silver compounds within shorter distances of the centres of molecular attraction. Alkaline development accomplished this to a very remarkable extent; but the method is only really practicable when applied to films containing silver bromide and chloride, and which is only slightly amenable to the alkaline development. The introduction of this developer is believed to be of American origin; and it is known that in the year 1862 Major C. Russell used it with the dry plates he introduced.

An alkaline developer consists of an alkali, a reducing agent and a restraining agent. These bodies, when combined and applied to the solid silver bromide or chloride, after being acted upon by light, were able to reduce the sub-bromide or sub-chloride, and to build up an image upon it, leaving the unaltered bromide intact, except so far as it was used in the building up. In 1877 Sir W. Abney investigated this action. A dry plate was prepared by the bath process in the usual manner (as described below), and exposed in the camera. The exposed film was covered with another film of collodio-bromide emulsion, which of course had not seen the light. An image was obtained from the double film by means of the alkaline developer, which penetrated through the upper unexposed film. The development was prolonged until an image appeared through the unexposed film, when the plate was fixed, washed and dried. A piece of gelatinous paper was cemented on the upper film, and a similar piece on the lower after both had been stripped off the glass. When quite dry the two papers were forcibly separated, a film adhering to each. The upper film, although never exposed to light, showed an image in some cases more intense than the under film. The action of the alkaline developer was here manifest: the silver bromide in close contiguity to the exposed particles was reduced to the metallic state. Hence, from this and similar experiments, Abney concluded that silver bromide could not exist in the presence of a freshly precipitated or reduced metallic silver, and that a sub-bromide was immediately formed. From this it will be seen that the deposited silver is well within the sphere of molecular attraction, and that consequently a less exposure (i.e. the reduction of fewer molecules of the sensitive salt) would give a developable image.

The alkalis used embraced the alkalis themselves and the mono-carbonates. The sole reducing agent up till recent times was pyrogallic acid. In the year 1880 Abney found that hydroquinone was even more effective than pyrogallic acid, its reducing power being stronger. Various other experimentalists tried other kindred substances, but without adding to the list of really useful agents until recently.

The following are some of the most effective:

**Eikonogen Developer.**
- Eikonogen: 25 parts.
- Sodium sulphite: 50 parts.
- Sodium carbonate: 50 parts.
- Potassium bromide: 1 part.
- Water: 1000 parts.

This is a one-solution developer, and acts energetically.

**Metal Developer.**

A and B solutions are mixed together in equal proportions.

Besides these, there are several more, such as adural, glycine, potato or unenveloped, which are used with many of our modern developers. They all give a black in lieu of that dark olive-green deposit of silver which is so often found with pyrogallic developers. All are alkaline developers, and the image is built up from the sensitive salt within the film. They are applicable to gelatin or colloid plates, but for the latter rather more bromide of an alkali is added to retard fogging.

Another set of developers for dry plates dependent on the reduction of the silver bromide and the metallic state is founded on the fact that certain organic salts of iron can be utilized. In 1877 M. Carey Lea of Philadelphia and William Willis announced almost simultaneously that a solution of ferrous oxalate in neutral potassium oxalate was effective as a developer, and from that time its use has been acknowledged. In 1882 J. M. Eder demonstrated that gelatino-silver chloride plates could be developed with ferrous citrate, which could not be so readily accomplished with ferrous oxalate. The exposure for chloride plates when developed by the latter was extremely prolonged.

In the same year Abney showed that if ferrous oxalate were dissolved in potassium citrate a much more powerful agent was formed, which allowed not only gelatino-chloride plates to be readily developed but also collodio-chloride plates. These plates were undevelopable except by the precipitation method until the advent of the agents last-mentioned owing to the fact that the film was reduced as the sub-chloride.

Amongst the components of an alkaline developer we mentioned a restrainer. This factor, generally a bromide or chloride of an alkali, serves probably to form a compound with the silver salt which has not been acted upon by light, and which is less easily reduced than is the silver salt alone—the altered particles being left intact. The action of the restrainer is regarded by some as due to its combination with the alkali. But whichever theory is correct the fact remains that the restrainer does make the primitive salt less amenable to reduction. Such restrainers as the bromides of the alkalis act through chemical means; but there are others which act through physical means, an example of which we have in the preparation of a gelatin plate. In this case the gelatin wraps up the particles of the silver compound in a colloidal sheath, as it were, and the developing solution only gets at them in a very gradual manner, for the natural tendency of all such reducing agents is to attack the particles on which least work has to be expended. In the case of silver sub-bromide the developer has only to remove one atom of bromine, whereas it has to remove two in the case of silver bromide. The sub-bromide formed by light and that subsequently produced in the act of development are therefore reduced. A large proportion of gelatin compared with the silver salt in a film enables an alkaline developer to be used without any chemical restrainer; but when the gelatin bears a small proportion to the silver such a restrainer has to be used. With collodion films the particles of bromide are more or less unenveloped, and hence in this case some kind of chemical restrainer is absolutely necessary. We may say that the organic iron developers require less restraining in their action than do the alkaline developers.

In Major Russell's process the plate was prepared by immersion in a strong solution of silver nitrate and then washed and a preservative agent added. The last-named substance being the last-named one being used, the halogen liberated by the action of light and the other to preserve the film from atmospheric action. Tannin, which Major Russell himself employed, is in fact the same as the halogen which acts as a varnish to the film. Other collodion dry-plate processes carried out by means of the silver-nitrate bath were very numerous at one time, many different organic bodies being also employed. The most cases ordinary bounded colloid developers were used, the use of, a small percentage of soluble bromide being as a rule added to it. When plates were developed by the alkaline method this extra bromide induced density, since it was the silver bromide alone which was amenable to it, the icelde being almost entirely unaffected by the weak developers which was at that time in general use.
PHOTOGRAPHY

Dry-Plate Bath Process.—One of the most successful bath dry-plate processes was introduced by R. Manners Gordon. The plate was given an edging of albumen and then coated with ordinary iodized collodion to which one gram per ounce of cadmium bromide had been added. It was kept in the silver-nitrate bath for ten minutes, after which it was washed thoroughly. The following preservative was then applied:

1. Gum arabic ........... 20 grs.
2. Sugar candy .......... 1 oz.
3. Water ................. 5 dr.
4. Gallic acid ........... 3 grs.
5. Water ................. 2 dr.

These ingredients were mixed just before use and, after filtering, applied for one minute to the plate, which was allowed to drain and set up to dry naturally. Great latitude is admissible in the exposure; it should rarely be less than four times or more than twenty times that which would be required for a wet plate under ordinary circumstances. The image may be developed with ferrous sulphate restrained by a solution of gelatin and glacial acetic acid, to which a solution of silver nitrate is added just before application, or by an alkaline developer.

In photographic processes not only has the chemical condition of the film to be taken into account but also the optical method. When light falls on a semi-opaque or translucent film it is scattered by the particles or grains that pass through the glass plate to the back surface of the film, and the rays are partly transmitted and partly reflected, a very small quantity of them being absorbed by the material of the glass. Theory points out that the strongest image will be from the back of the glass that should take place at the critical angles. In 1875 Ramsden investigated the subject and proved that practice agreed with theory in every respect, and that the image of a point of light in development on a plate was surrounded by a ring of reduced silver caused by the reflection of the scattered light from the back surface of the glass, and that this ring was shaded inwards and outwards in such a manner that the shading varied with the intensity of the light reflected at different angles. To avoid "halation," as this phenomenon is called, it was usual to cover the back of dry plates with some material which should be in optical contact with it, and as nearly as possible of the same density as glass, and which at the same time should absorb all the photographically active rays. This was called "backing a plate."

Collodion Emulsion Process.—In 1864 W. B. Bolton and B. J. Sayce published the germ of a process which revolutionized photographic manipulations. In the ordinary collodion process a sensitive film is procured by coating a glass plate with collodion containing the iodide and bromide of some soluble salt, and then, when set, immersing it in a solution of silver nitrate in order to form silver iodide and bromide in the film. The question that presented itself to Bolton and Sayce was whether it might not be possible to get the sensitive salts of silver formed in the collodion in the same state as was given to a plate by merely letting this collodion containing the iodide to suspend in suspension flow over the glass plate. Gaudin had attempted to do this with silver chloride, and later G. W. Simpson had succeeded in perfecting a printing process with collodion containing silver chloride, citric acid and silver nitrate; but the chloride until recently has been considered a slow working salt, and nearly incapable of development. Up to the time of W. B. Bolton and B. J. Sayce's experiments silver iodide had been considered the staple of a sensitive film on which to take negatives; and though bromide had been used by Major Russell and others, it had not met with so much favour as to lead to the omission of the iodide. At the date mentioned the suspension of silver iodide in collodion was not thought practicable, and the inventors of the process turned their attention to silver bromide, which they found could be secured in such a fine state of division that it remained suspended for a considerable time in collodion, and even when precipitated could be resuspended by simple agitation. The outline of the method was to dissolve a soluble bromide in plain collodion, and to add to it drop by drop an alcohol solution of silver nitrate, the latter being in excess or defect according to the will of the operator. To prepare a sensitive surface the collodion containing the unemulsified sensitive salt was poured over a glass plate, allowed to set, and washed till all the soluble salts resulting from the double decomposition of the soluble bromide and the silver nitrate, together with the unaltered soluble bromide or silver nitrate, were removed, when the film was exposed wet, or allowed to dry and then exposed. The rapidity of these plates was not in any way remarkable, but the process had the great advantage of doing away with the sensitizing nitrate of silver bath, and thus avoiding a tiresome operation. The plates were developed by the alkaline method, and gave images which, if not primarily dense enough, could be intensified by the application of pyrogallic acid and silver nitrate as in the wet collodion process. Such was the crude germ of a method which was destined to effect a complete change in the aspect of photographic negative taking; but for some time it lay dormant. In 1873 it was at first subjected to a fresh trial of it, since the plates often became veiled on development. 3

M. Carey Lea of Philadelphia, and W. Cooper, jun., of Reading, may be said to have given the real impetus to the method. Carey Lea, by introducing an acid into the emulsion, established a practicable collodion emulsion process, which was rapid and at the same time gave negative pictures free from veil. To secure the rapidity Carey Lea employed a fair excess of silver nitrate, and Colonel H. Stuart Wortley gained further rapidity by a still greater increase of it; the free use of acid was the only means by which this could be effected without hopelessly spoiling the emulsion. The addition of the mineral acids such as Carey Lea employed is to prevent the formation of (or to destroy when formed) any silver sub-bromide or silver iodide which might otherwise convert the silver bromide might take place. Abney first showed the theoretical effect of acids on the sub-bromide, as also the effect of oxidizing agents on both the above compounds (see below). A more valuable modification to improve the method was added by W. B. Bolton, one of the originators of the process, who allowed the ether and the alcohol of the collodion to evaporate, and then washed away all the soluble salts from the gelatinous mass formed of pyroxylin and sensitive salt. After washing a second time, the plates were coated with a solution of gelatin, naturally or washed with alcohol, and then the pyroxylin redisolved in ether and alcohol, leaving an emulsion of silver bromide, silver chloride and gelatin, and mixtures of all suspended in collodion. In this state the plate could be coated and dried at once for exposure. Sometimes, in fact generally, preservatives were used, as in the case of dry plates with the bath, in order to prevent the atmosphere from spoiling the surface of the surface of the plate. This modification had the great advantage of sparing a large quantity of sensitive salt to be prepared of precisely the same value as to rapidity of action and quality of film.

A great advance in the use of the collodion bromide process was made by Colonel Stuart Wortley, who in June 1873 made known the powerful nature of a strongly alkaline developer as opposed to the weak one which up to that time had usually been employed for a collodion emulsion plate for any other purpose. An example of the preparation of a collodion emulsion and the developer is the following: 24 oz. of alcohol, 5 oz. of ether, 75 grains of pyroxylin. In 1 oz. of alcohol are dissolved 200 grains of zinc or silver chloride, or it is then saturated with 4 or 5 grains of nitrate, and added to half the above collodion. In 2 drachms of water are dissolved 330 grains of silver nitrate, 1 oz. of alcohol being added. The silver alcohol solution is poured into the other half of the collodion and the brominated collodion dropped in, care being taken to break the operations. An emulsion of silver bromide is formed in suspension; and it is in every case left for 10 to 20 hours to what is technically called "ripen," or, in other words, to become creamy when poured out upon a glass plate. When the emulsion has ripened it may be used at once or be poured out into a flat dish and the solvents allowed to evaporate till the pyroxylin becomes gelatinous. In this state it is washed in water till all the soluble salts are carried away. After this it may be spread out on a cloth and dried or treated with two or three doses of alcohol, and then dissolved in equal parts of alcohol (specific gravity, 0.80) and ether (specific gravity, 0.720). In this condition the negative is ready for use, and a glass plate can be coated with it and the film dried, or it may be washed and some of the many preservatives, such as albumen, bichloride, gum, &c., applied. The type of a useful alkaline developer for collodion plates is as follows:—

1. Pyrogallic acid .......... 96 grs.
2. Alcohol ................ 1 oz.
3. Potassium bromide ...... 12 grs.
5. Ammonium carbonate ...... 80 grs.

To develop the plate 6 minims of No. 1, 1 drachm of No. 2, and 3 drachms of No. 3 are poured over it for exposure, and after washing the preservative off under the tap. Sometimes the

3 An account of Sayce's process is to be found in the Photographic News of October 1865, or the Photographic Journal of the same date.

4 The advantages of this salt were pointed out by Leon Warnerke in 1875.

The warming process introduced by Bennett was soon superseded. Colonel Stuart Wortley in 1879 announced that, by raising the temperature of the emulsion to about 150°F., instead of days being required to give the desired sensibility only a few hours were necessary. A further advance was made by boiling the emulsion, first practised, we believe, by G. Mansfield in 1879. Another improvement was effected by W. B. Bolton by emulsifying the silver salt in a small quantity of gelatin and then raising the emulsion to boiling point, boiling it for from half an hour to an hour, when extreme rapidity was attained. Many minor improvements in this process have been made from time to time. It may be useful to give an idea of the relative rapidities of the various processes we have described.

Gelatin Emulsions.

The following is an outline of two representative processes. All operations should be conducted in light which can act but very slightly on the sensitive salts employed, and this is more necessary with this process than with others on account of the extreme ease with which the equilibrium of the molecules is upset in giving rise to the molecule which is developable. The light to work with is gaslight or candlelight passing through a sheet of Chance's stained red glass backed by orange paper. Stained red glass allows but few chemically effective rays to pass through it, whilst the orange paper diffuses the light. If daylight be employed, it is as well to have a double thickness of orange paper. The following should be weighed out:

1. Potassium iodide 5 grs.
2. Potassium bromide 155
3. Nelson's No. 1 photographic gelatin 30
4. Silver nitrate 70
5. Autotype or other hard gelatin 100
6. Nelson's No. 1 gelatin 100

Nos. 3 and 5 are rapidly covered with water or washed for a few seconds under the tap to get rid of any dust. No. 2 is dissolved in 1 oz. of water, and a little tincture of iodine added till it assumes a light, cherry-colour. Add, in 60 minutes of water, No. 4 is dissolved in 1 oz. of water, and No. 3 is allowed to swell up in 1 oz. of water, and is then dissolved by heat. All the flasks containing these solutions are placed in water at 150°F., and carried into the darkroom in the appropriate one. Each room containing solutions is called; Nos. 3 and 4 are then mixed together in a jar or flask, and No. 2 added drop by drop till half its bulk is gone, when No. 1 is added to the remainder, and the double solution is dropped in as before. When all is dissolved the light is turned off, and very quickly, which is very rapidly when examined by gaslight, or orange by daylight. The flask containing the emulsion is next placed in boiling water, which is kept in a state of ebullition for about three-quarters of an hour. It is then ready, when the contents of the flask have cooled down to about 100°F., for the addition of No. 5, which should be left in the interval placed in 2 oz. of water to swell and finally be dissolved. The gelatin emulsion thus formed is placed in a cool place to set, after which it is turned into a piece of coarse canvas or mosquito netting made into a bag. By squeezing, threads of gelatin containing the sensitive salt can be made to pass into the cold water, and thus gelatin threads are extracted. This is readily done in two or three hours by frequently changing the water, or by allowing running water to flow over the emulsion-threads. The gelatin is next drained by straining canvas over a jar and turning out the threads on to it, after which it is placed in a flask, and warmed till it dissolves, half an ounce of alcohol being added. Finally it is filtered through chamois leather or wasandsawn calico. In this state it is ready for the plate.
to the gelatin the remainder of No. 5 is added before the addition of the alcohol, and before filtering.

Coating the Paper.—When plates are best cleaned with nitric acid, washed, and then treated with potash solution, rinsed again, and dried with a clean cloth. They are then ready for receiving the emulsion, which, after being warmed to about 120° F., is poured on to them to cover well the surface. This being done, the plates are placed on a level shelf and allowed to stay there till the gelatin is thoroughly set; they are then put in a drying cupboard, through which a current of warm air is made to pass. It should be remarked that any evaporation that may take place from the moisture from the plates. They ought to dry in about twelve hours, and they are ready for use.

Exposure.—With a good emulsion and on a bright day the exposure is of the utmost importance for the nature of the gelatin, or one-sixteenth of that of the focal distance, should not be more than one-half to one-fifth of a second. This time depends, of course, on the nature of the subject; if there be fog, or if the immediate foreground is rather flat, it will be longer. In the portrait-studio, under the same circumstances, an exposure with a portrait lens may be from half a second to four or five seconds.

Development of the Plate.—To develop the image either a ferrous oxalate solution or alkaline pyrogallic acid may be used. No chemical restrainer such as potassium bromide is necessary, since the gelatin itself acts as a physical restrainer. If the gelatin develops well, the following may be taken as a good standard:

<table>
<thead>
<tr>
<th>Solution</th>
<th>Amount</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pyrogallic</td>
<td>490 grs</td>
</tr>
<tr>
<td>Citric acid</td>
<td>1 oz.</td>
</tr>
<tr>
<td>Water</td>
<td>10 oz.</td>
</tr>
<tr>
<td>Potassium bromide</td>
<td>1 oz.</td>
</tr>
<tr>
<td>Water</td>
<td>1 oz.</td>
</tr>
<tr>
<td>Ammonium</td>
<td>880 grs</td>
</tr>
<tr>
<td>Water</td>
<td>9 oz.</td>
</tr>
</tbody>
</table>

One dram of each of these is taken and the mixture made up to 2 oz. with water. The plate is placed in a dish and the above poured over it without stopping, whereupon the gelatine gradually appears and, if the exposure has been properly timed, gains sufficient density for printing purposes. It is fixed in a solution of hyposulphite of soda, as in the other processes already described and then thoroughly washed for two or three hours to eliminate all the soluble salt. This long washing is necessary to account of the nature of the gelatin.

Intensifying the Negative.—Sometimes it is necessary to intensify the negative, which can be done in a variety of ways with mercury salts. An excellent plan, introduced by Chapman Jones, is to use a saturated solution of mercuric chloride in water. After thorough washing the negative is treated with ferrous oxalate. This process can be repeated till sufficient density is attained. With most other methods with mercury the image is apt to become yellow and to fade; with this apparently it is not.

Varnishing the Negative.—The negative is often protected by receiving first a film of plain collodion and then a coat of shellack or other varnish. This protects the image from moisture and also from becoming stained with the silver nitrate owing to contact with the sensitive paper used in silver printing. Another varnish is a solution of celloidin in amyl acetate. This is an excellent protection against damp.

Printing Processes.

The first printing process may be said to be that of Fox Talbot (see above), which has continued to be generally employed (with the addition of albumen to give a surface to the print—an addition first made, we believe, by Fox Talbot).

Paper for printing is prepared by mixing 150 parts of ammonium chloride with 240 parts of spirits of wine and 2000 parts of water, thrashing the proportions as far as possible. The ingredients are dissolved, and the whites of fifteen fairly-sized eggs are beaten up to a froth. In hot weather it is advisable to add a drop of carbolic acid to prevent decomposition. The albumen is allowed to stand for an hour, when it is filtered through a number of diatomaceous earth placed in a funnel, or through two or three thicknesses of fine muslin, and transferred to a flat dish. The paper is cut of convenient size and allowed to float on the solution for about a minute, when it is ready for use. If it is not seized and left on the dish, it is then hung up to dry, when it will absorb the excess water and the remaining components are added. It is next filtered, and the paper allowed to float on it for three minutes, then withdrawn and dried.

Sensitising Bath.—To sensitise the paper it is floated on a 10% solution of silver nitrate for three minutes. It is then hung up and allowed to dry, after which it is ready for use. To print the image the paper is placed in a printing frame over a negative and exposed to light. It is allowed to print till such time as the image appears rather darker than it should finally appear.

Toning and Fixing the Print.—The next operation is to tone and fix the print. In the earlier days this was accomplished by means of a solution of a mixture of hyposulphite of soda and gold chloride. This gilded the darkened parts of the print which light had reduced to the semi-metallic state; and on the removal of the chloride by means of hyposulphite of soda and ammonia, the gold of metallic nature, silver and gold was left behind. There was a suspicion, however, that part of this coloration was due to a combination of sulphur with the silver, not that pure silver sulphide was produced, although, but the sulphur dioxide which this seems to be liable to change. This gave place to a method of alkaline toning, or rather, we should say, of neutral toning, by employing gold chloride with a salt, such as the carbonate or bicarbonate. In this case there was no danger of sulphuration during the toning, to which the method by sel d’or was prone owing to the decomposition of the hyposulphite. The substances which can be employed in toning silver prints are the salts of silver, gold, and gold chloride, the latter being readily displaced by a stronger acid, such as nitric acid, which must exist in the paper after printing. This branch of photography owes much to the Rev. T. F. Hardwich, he having carried on extensive researches in connection with it during 1854 and subsequent years. A. Davanne and A. Girard, a little later, also investigated with the material with fruitful results.

The following may be taken as two typical toning-baths:

<table>
<thead>
<tr>
<th>Toning Bath</th>
<th>Use</th>
</tr>
</thead>
<tbody>
<tr>
<td>Gold chloride</td>
<td>2 parts</td>
</tr>
<tr>
<td>Chloride of lime</td>
<td>2 parts</td>
</tr>
<tr>
<td>Chlorate of potash</td>
<td>4 parts</td>
</tr>
<tr>
<td>Water</td>
<td>8000 grs</td>
</tr>
</tbody>
</table>

These are mixed together, the water being warmed. When cooled the solution is ready for use. In toning prints there is a distinct difference in the action of this method according to the acid employed. Thus in the first two baths the print must be thoroughly washed in water to remove all free silver nitrate, that salt forming no part in the chemical reactions. On the other hand, where free silver chloride is said to be used, the nitrate is removed after a chlorine absorbent is a necessity. In 1872 Abney showed that with such a toning-bath free silver nitrate might be eliminated, and if the print were immersed in a solution of a salt such as lead nitrate the toning action proceeded rapidly without causing any fading of the image whilst toning, which was not the case when the free silver nitrate was totally removed and no other chlorine absorbent substituted. This was a great saving factor, and one which had been overlooked. In the third bath the free silver nitrate should only be partially removed by washing. The print, having been partially washed or thoroughly washed, as the case may be, is immersed in the toning-bath till the print attains a purple or bluish tone, after which it is ready for fixing. The solution used for this purpose is a 20% solution of hyposulphite of soda, to which it is best to add a few drops of ammonia in order to render it alkaline. About ten minutes suffice to complete the conversion of the chloride into hyposulphite of silver, which is soluble in hyposulphite of soda and can be removed by washing.

The organic salts of silver seem, however, to form a different salt, silver is partially insoluble, but which the ammonia helps to reduce. If it is not removed there is a sulphur compound left behind, according to J. Spiller, which by time and exposure becomes yellow.

The use of potassium cyanide for fixing prints is to be avoided, as it is liable to affect the gold chloride and produce a gold, and would render the print a ghost. The washing of silver prints should be very complete, since it is said that the least trace of hyposulphite remaining renders the fading of the image a mere matter of time. The stability of a photographic print after being fixed and immersed into a fixing bath, or even after being fractionated by washing, is a matter of time. The destruction of the hyposulphite by time is not the occasion of fading, but that its hygroscopic character is. This, however, is a moot point. It is usual to wash the prints some hours in running water, and it is a fact that a dry print, if allowed to remain in a wet room, for dead prints, on which colouring is to take place, plain salted paper is useful. It can be made of the following proportions—90 parts of ammonium chloride, 100 parts of sodium citrate, 10 parts of gelatin, 5000 parts of distilled water. This gelatin is first dissolved in the water and the remaining components are added. It is next filtered, and the paper allowed to float on it for three minutes, then withdrawn and PC.

Sensitising Bath.—To sensitize the paper it is floated on a 10% solution of silver nitrate for three minutes. It is then hung up and allowed to dry, after which it is ready for use. To print the image the paper is placed in a printing frame over a negative and exposed to light. It is allowed to print till such time as the image appears rather darker than it should finally appear.

Different tones can thus be given to a print by different toning-baths; and the gold itself may be deposited in a ruddy form or in a blue form. The former molecular condition gives the red and sepia tones, and the latter the blue and black tones. The degree of minute subdivision of the gold may be concealed when it is
PHOTOGRAPHY

That stated, on a couple of sheets of albumized paper fully printed, the gold necessary to give a decided tone does not exceed half a grain.

**Collodio-chloride Silver Printing.**—In the history of the emulsion processes we stated that Gaudin attempted to use silver chloride suspended in collodion, but it was not till the year 1840 that any practical use was made of the suggestion so far as silver printing was concerned. In the autumn of that year George Wharton Simpson worked out a method which has been most successfully employed. The formula appended is Simpson's:—

1. Silver nitrate 60 parts.
2. Distilled water 60 parts.
3. Silver chloride 1000 parts.
4. Alcohol 64 parts.
5. Alcool 1000 parts.

To every 1000 parts of plain collodion 30 parts of No. 1, previously mixed with parts of alcohol, are added; 60 parts of No. 2 are next mixed with the collodion, and finally 30 parts of No. 3. This forms an emulsion of silver chloride and also contains citric acid and silver nitrate. The defect of this emulsion is that it contains a large proportion of soluble salts, which are apt to crystallize out on drying, more particularly if it be applied to glass plates. The addition of the citric acid and the excess of silver nitrate is the key to the whole process; for, unless some body were present which on exposure to light was capable of forming a highly organic oxide of silver, no vigorous would be obtained in printing. If pure chloride be used, though an apparently strong image would be produced on the glass, the only effect would be to detach a trace of it from the plate, and the print would be worthless. The collodio-chloride emulsion, may be applied to glass, or to paper, and the printing carried on in the usual manner. The toning takes place by means of the chloride of silver, produced by the sulphuric acid, and gold, which is practically a return to the sel d'or bath. The organic salt formed in this process does not seem so prone to be decomposed by keeping as does that formed by albumen, and the washing can be more completely removed. There are in the market several papers which are called collodio-chloride.

**Gelatino-citra-chloride Emulsion.**—A modified emulsion printing process was introduced by Abney in 1851, which consisted in suspending silver chloride and silver citrate in gelatine, used with no excess of silver present. The formula of producing it is as follows:—

1. Sodium chloride 40 parts.
2. Potassium citrate 40 parts.
3. Water 500 parts.
4. Silver nitrate 150 parts.
5. Water 500 parts.
6. Gelatin 300 parts.
7. Water 1700 parts.

Nos. 2 and 3 are mixed together whilst warm, and No. 1 is then gently added, the gelatin solution being kept in brisk agitation. This process, however, was the invention of a man who was not a chemist, and the emulsion was practically worthless. The gelatin containing the suspended salts is heated for five minutes at boiling point, when it is allowed to cool and subsequently slightly washed, as in the gelatino-bromide emulsion. It is then ready for application to paper or glass. The gelatin is one of the best for producing emulsions of gold chloride. In a gelatin case, the silver and gold are deposited in the metallic state. Another developer is a 2% solution of potassium ferrocyanide to which a trace of nitric acid has been added, sufficient to give a red coloration. This developer is placed most readily by letting the paper float on this solution.

**Printing with Salts of Uranium.**—The sensitiveness of the salts of uranium to light seems to have been discovered by Poitevin, who in 1839 was succeeded in applying to photography by J. B. Burnett in England. One of the original formulæ consisted of 20 parts of uranic nitrate with 600 parts of water. Paper, which is better if slightly sized with gelatin, is floated on the solution. When dry it is exposed beneath a negative, and a very faint image is produced; but it can be developed into a strong one by 6 to 10% solution of silver nitrate to which a trace of acetic acid has been added, and then dried. In both cases the silver and gold are deposited in the metallic state. Another developer is a 2% solution of potassium ferrocyanide to which a trace of nitric acid has been added, sufficient to give a red coloration. The paper is developed most readily by letting the paper float on this solution.

**Soft-Toning Papers.**—There are several soft-toning papers based on the chloride emulsion process. These contain the necessary amount of silver chloride in the print. The print is made in the ordinary way and then immersed in salt and water or in some cases potassium sulphocyanide. The print is finished by immersing in weak hypo-sulphite of soda.

**Carbon Prints.**—The first mention of the use of potassium bichromate for printing purposes seems to have been made by Mungo Pontin in May 1839, when he stated that paper, if saturated with this salt and dried, and then exposed to the sun's rays through a drawing, would produce a yellow picture on an orange ground, nothing more being required to fix it than washing it in water, when a white picture on an orange ground was obtained. In 1840 Edmond Becquerel announced that paper sized with iodide of starch and soaked in potassium bichromate was, on drying, more sensitive than unsized paper. Joseph Dixon of Manchester, in 1842, published, in the following year, process, by using gum arabic with potassium bichromate spread upon a lithographic stone, and, after exposure of the sensitive surface through a layenote, by washing away the unaltered gum and inked portions of the stone by means of a solution of potassium bichromate, with slight modifications, has been used by Simonova and Toovey of Brussels, and produces excellent results. Dixon's method, however, was published in the "Scientific American" for 1854, and consequently, as regards priority, as regards priority, is not correctly attributable to him. The process of soft-toning, as introduced by Abbé Laborde in 1858, whilst describing a kindred process in a note to the French Photographic Society. He says, "In the sensitive film, however thin it may be, two distinct surfaces must be recognized, an outer surface consisting merely of gelatin and a second the paper. The action of light commences on the outer surface; in the washing, therefore, the half-tones lose their hold on the paper and are removed away. Slight agitation is required to get rid of this defect in carbon printing. In a paper of the Photographic Society of London he says, "There are two essential requisites, . . . (2) that in printing the paper should have its emulsion side (and not the reverse) in contact with the positive, so placed in contact with the negative in the pressure-frame, as it is only by printing in this way that we can expect to be able afterwards to remove by washing the unacted-upon portions of the emulsion. In a positive of this sort printed from the front of the paper the attainment of half-tones by washing away more or less depth of the image, according to the depth to which it has been hardened, is prevented by the insoluble parts being on the surface, in consequence of the process of action of the light in washing; so that either nothing is removed, or by steeping very long till the inner soluble part is softened and a trace may be removed bodily away, leaving the paper white." This method of exposing to light in contact with the negative, and developing afterwards, as the carbon print, was that of Poitevin, who, in 1859, patented a process in which, after exposure to light of the gelatin films, the gelatin emulsion was washed away, and the paper placed in warm water, where it separated from the paper support and could be transferred to glass. Poitevin successfully opposed this patent, for he had used this means of detachment in his positive process. There was also the case of Simonova and Toovey, who used an excess of potassium bichromate, and were forced to leave the paper white.

In 1860, Simonova and Toovey published a process of carbon printing in which the positive was printed on a carbonized paper coated with a mixture of silver nitrate and silver nitrate, mixed with a solution of potassium dichromate and potassium bichromate. After exposure to light the positive was washed out, and washing is transferred to the glass by the use of chloroform, to which it was made to adhere by pressure. The print was immersed in hot water, the paper backing stripped off, and the soluble gelatin contained in the emulsion matter washed away. The picture could then be transferred to its final support of paper. In 1869 J. R. Johnson of London took out a patent in which he claimed that carbon-tissue which had been soaked in water for a short period, by which a tendency to uniformity of tone was produced, was coated with a mixture of gelatin and silver nitrate, coated with a solution of potassium dichromate, and washed with a solution of carbon disulphide, so that the carbon print was obtained, and printed insoluble by chrome solutions. In 1874 J. R. Sawyer patented a flexible support for developing upon: this was a sized paper coated with gelatin and treated with an ammoniacal solution of chrome, in which the print was washed, without losing its original shape, on which wax or resin was rubbed. The advantage of this flexible support is that the dark parts of the picture are made to contract from the lighter parts, which were apt to do to when a metal plate was used, as was the case in Johnson's original process. The picture is produced upon the paper finished as above; the carbon print is made since, carbon-printing has arrived at its present state of perfection.

According to P. E. Liesegang, the carbon-tissue when prepared on a large scale consists of from 120 to 150 grains of gelatin (a soft kind), 15 grains of soap, 21 grains of sugar and from 4 to 8 grains of dry colouring matter. The last-named may be of various kinds, and lamp-black pigment is used to the clearest such as alginin. The gelatin, sugar, and soap are put in water and allowed to stand for an hour, and then melted, the liquid afterwards receiving the
PHOTOGRAPHY

PHOTOGRAPHY was in Melbourne the Asser at 494 Printing Munich. Marc Antoine A. Gaudin claimed the principle of the process, insisting that it was old, and basing his pretensions on the fact that he had a number of patents. The process was published for two or three years afterwards, when it was divulged by Ohm and Grossman, one of whom had been employed by Albert of Munich, and had endeavoured to introduce a process which resembled Albert's earlier efforts. The name of "Lichtdruck" was given about this time to these surface-processing prints, and Albert may be considered, if not the inventor, at all events the perfecter of the method. Another modification of "Lichtdruck" was patented in England by Ernest Edwards under the name of "heliototype."

Woodbury Type.—This process was invented by W. Woodbury about the year 1864, though we believe that J. W. Swan had been working independently in the same direction about the same time. In January 1864 a description of the invention was published in the Photographic News. Mr. Antoine A. Gaudin claimed the principle of the process, insisting that it was old, and basing his pretensions on the fact that he had a number of patents. Photographs in Natural Colours.

The first notice on record of coloured light impressing its own colours on a sensitive surface is in the passage already quoted from the Varbelehre of Goethe, where T. J. Seebeck of Jena (1810) describes the impression he obtained on paper by a photograph of a colour.uel of a coals. This process is known by the name of "heliototype."

Athenaeum, No. 621) gave a somewhat similar description. In 1848 Edmond Bécquerel succeeded in reproducing upon a daguerreotype plate not only the colours of the spectrum but at a certain point, the colours of drawings and objects. His method of proceeding was to give the silver plate a thin coating of silver chloride by immersing it in ferric or cupric chlorides. It may also be immersed in chlorine water till it takes a feeble rose tint. Bécquerel preferred to chlorinize the plate by immersion in a solution of hydrochloric acid in water, attaching it to the positive pole of a voltaic couple, whilst the other pole he attached to a platinum plate also immersed in the acid solution. After a minute's subjection to the voltaic plate the plate was hung in a dark room and a blue tint, which order was again repeated. When the violet tint appeared for the second time the plate was withdrawn and dried over a spirit-lamp. In this state it

the whole became coagulated rendered these unmanageable. It at last occurred to him that if the hardening action of light were to be produced before exposing the front surface to the film and the image, the necessary hardiness might be given to the gelatin without adding any chemical hardener to it. In Tessie de Motay's process the objects to be photographed were fixed in a solution of silver nitrate to which a hardening agent had been added, the whole being exposed, afterwards washing, the silver nitrate solution, the tissue sensitive at once, 120 grains of potassium bichromate should be mixed with the ingredients in the above formula. The carbon-tissue when prepared should be placed on a support of transparent gelatin in 40 parts of water. This is effected by turning up about 1 in. from the end of the sheet of tissue (cut to the proper size), making a roll of it, and letting it roll along the surface of the sensitive solution, where it is allowed to remain till the gelatin film feels soft. It is then taken off and hung up to dry in a dark room through which a current of dry warm air is passing. Tissue dried quickly, though not so sensitive, is more manageable to work on than if more slowly dried. As the tissue is coloured, it is not possible to ascertain by inspection whether the printing operation is sufficiently carried out, and in order to ascertain this it is usual to place a piece of ordinary silvered paper in an actinometer, or photometer, alongside the carbon-tissue to ascertain the amount of light that has acted on it. There are several devices for ascertaining this amount, the simplest being the application of a certain number of streaks of gold-beater's skin. The value of 1, 2, 3, &c., thicknesses of the skin as a screen to the light is ascertained by experiment. Suppose it is judged that a sheet of tissue under some one negative ought to be exposed for it to be correctly fixed, to determine the thicknesses, chloride of silver paper is placed alongside the negative beneath the actinometer and allowed to remain there until it takes a visible tint beneath a number of thicknesses equivalent to the strength of the light expected. After the printing-process is completed, the double transfer is made—i.e., it is placed in a dish of cold water, face downwards, along with a piece of moist silver chloride paper. When the edges of the two papers curl up, its surface and that of the flexible support are brought together and placed flat. The water is pressed out with an india-rubber squeeze or "squeegee" and the two surfaces adhere. About a centimetre of the edges of the papers is soaked with water, and this edge is left towards the rollers. When the edges of the papers have been pasted, the paper is pulled through and the plate fixed, the gelatin solution next it becoming soluble, can be stripped off, leaving the image (reversed as regards right and left) on the flexible support. An impression of the image is then made by rolling sheets of paper, or piece of gelatin and pigment. When dried the image is transferred to its permanent support. This usually consists of white paper coated with gelatin and made insoluble with chrome alum, though it may be immersed in silver chloride or gelatin and dried, or the transfer-paper is made to receive greasy ink on those parts which had been affected by light. But Paul Ordloh seems to have made the discovery previously to 1854, for in his patent of that year he states that his designs were made by using a black plate before being exposed to the light. C. M. Tessie de Motay (in 1865) and C. R. Marechal of Metz, however, seem to have been the first to produce half-tones from gelatin films by means of greasy ink. Their general procedure consisted in coating glass plates with gelatin, having it exposed to solar light, or ammonium bichromate or tri-chromate and mercuric chloride, then treating with silver olate, exposing to light through a negative, washing again, and rendering it greasy and printing from the plate as for an ordinary lithograph. The results obtained by the Frenchmen were very good, and illustrations executed by them are to be found in several existing works. The method of producing the plates, however, was more complicated, and Tessie de Motay was 1870 (see LITHOGRAPHY AND PROCESS).
produced the spectrum colours, but it was found better to heat the plate till it assumed a rose tint. At a later date Niepce de St. Victor chlorinized by chloride of lime, and made the surface more sensitive by applying a solution of lead chloride in dextrin. G. W. Simpson also obtained coloured images on silver chloride emulsion in collodion, but they were less vivid and satisfactory than those obtained on daguerreotype plates. Poitevin obtained coloured images on ordinary silver chloride paper by preparing it in the usual manner and washing it and exposing it to light. It was then immersed in a solution of potassium bichromate and cupric sulphate, and dried in darkness. Sheer exposed paper gave coloured images from coloured pictures, which he stated could be fixed by sulphuric acid (Comptes rendus, 1836, 61, p. 11).

In the Bulletin de la Société Française (1874) Colonel St. Florent described experiments which he made with the same object. He immersed ordinary or albuminized paper in silver nitrate and afterwards plunged it into a solution of uranium nitrate and zinc chloride acelulated with hydrochloric acid; it was then exposed to light till it took a violet, blue or lavender tint. Before exposure the paper was floated on a solution of mercuric nitrate, its surface dried, and exposed to a coloured image.

In 1841, Robert Hunt published some results of colour-photography by means of silver fluoride. A paper was washed with silver nitrate and with sodium fluoride, and afterwards exposed to the spectrum. The action of the spectrum commenced at the centre of the yellow ray and rapidly proceeded upwards, arriving at its maximum in the blue ray. As far as the indigo the action was uniform, whilst in the violet the paper took a brown tint. When it was previously exposed, however, a yellow space was occupied where the yellow rays had acted, a green band where the green had acted, whilst in the blue and indigo it took an intense blue, and over the violet there was a bluish tint. In 1858, he wrote: "If it be so that the nature of the chloride used to obtain the silver chloride has a great effect on the colours impressed; and Niepce in 1857 made some observations on the relationship which seemed to exist between the coloured flames produced by the metal and the colour impressed on a plate prepared with a chloride of such a metal. In 1880 Abney showed that the production of colour really resulted from the oxidation of the chloride that was coloured by light. Plates immersed in a solution of hydrogen peroxide took the colours of the spectrum much more rapidly than when not immersed, and the size of the molecules seemed to regulate the colour. He further stated that the whole of the spectrum colours might be derived from a mixture of two or at most three sizes of molecules.

In 1841, Karl Wilhelm Scheele published the results of his experiments on silver salts:

"I precipitated a solution of silver by sal-ammoniac; then I edulcorated it and dried the precipitate and exposed it to the beams of the sun for two weeks; after which I stirred the powder, and renewed the process the caustic spirit of sal-ammoniac (strong ammonia) on this, in all appearance, black powder, and set it by for digestion. This menstruum dissolved a quantity of luna cornua (horn silver), though some black powder remained undissolved. The powder, which had been washed, was, for the greater part, dissolved by a pure acid of nitre (nitric acid), which, by the operation, acquired volatility. This solution I precipitated again by means of sal-ammoniac into horn silver. Hence it follows that the blackness which the luna cornua acquires from the sun’s light, and likewise the solution of silver poured on chalk, is silver by reduction... I mixed so much distilled silver nitrate and nitric acid that just covered this powder. The half of this mixture I poured into a white crystal phial, exposed it to the beams of the sun, and shook it several times each day; the other half I set in a dark place. After having exposed the one mixture during the space of two weeks, I filtrated the water standing over the horn silver, grown already black; I let some of this water fall by drops in a solution of silver, which was immediately precipitated into horn silver."

This, as far as we know, is the first intimation of the reducing action of light. From this it is evident that Scheele had found that the silver chloride was decomposed by the action of light, and that some form of light was required to effect the experiments and found that chlorine is really liberated from the chloride; but it is necessary that some body should be present which would absorb the chloride, or, at all events, that the chloride should be free to escape. A tube of dried silver chloride, sealed up in vacuo, will not discolour in the light, but keeps its ordinary white colour. A pretty experiment is to seal up in vacuo, at one end of a bent tube, perfectly dry chloride, and at the other a drop of mercury. The mercury vapour volatilizes to a certain extent and fills the tube. When exposed to light the chloride is liberated from the chloride, and calomel forms on the sides of the tube. In this case the chloride darkens. Again, dried silver chloride is sealed up in vacuo; the sealed tube is kept in a place where some light is, and it will be found that the combination of the chloride with the hydroxide. Poitevin and H. W. Vogel first enunciated the law that for the reduction by light of the haloid salts of silver halogen absorbents were necessary, and it was by following out this law that the present rapidity in obtaining camera images has been rendered possible. To put it briefly, then, the visible action of light is a reducing action, which is aided by or entirely due to the fact that other bodies are present which will absorb the halogens.

In the above we have alluded to the visible results on silver salts. It by no means follows that the exposure of a silver salt to light for such a brief period as to leave no visible effect must be due to the same effect, that is, that any of the molecules are absolutely reduced or split up by the light. That this or some other action takes place is shown by the fact that the silver salt is capable of alkaline development, that is, the particles...
which have suffered a change in their molecules can be reduced to metallic silver, whilst those which have not been acted upon remain unaltered by the same chemical agency. Two theories have been offered to explain the invisible change which takes place in the salts of silver. One is based on the supposition that the molecules of the salt can rearrange their atoms under the vibrations caused by the ether waves placing them in more unstable positions than they were in before the impact of light took place. This, it is presumed, would allow the developer to separate the atoms of such shaken molecules when it came in contact with them. The other theory is that, as in the case of the visible effects of light, some of the molecules are at once reduced and that the developer finishes the disintegration which the light has begun. In the case of the alkaline development the unaltered molecules next those primarily reduced combine with the reduced silver atom and again form an unstable compound and are in their turn reduced.

The first theory would require some such action as that just mentioned to take place and cause the invisible image formed by the shaking apart of the light-stricken molecules to become visible. It is hard to see why other unacted upon molecules close to those which were made unstable and which have been shaken apart by the developer should themselves be placed in unstable equilibrium and amenable to reduction. In the second theory, called the "chemical theory," the reduction is perfectly easy to understand. Abney adopts the chemical theory as the balance of unsubstantiated evidence is in its favour. There is another action which seems to occur almost simultaneously when exposure takes place in the absence of an active halogen absorber, as is the case when the exposure is given in the air, that is, an oxidizing action occurs. The molecules of the altered haloid salts take up oxygen and form oxides. If a sensitive salt be briefly exposed to light and then treated with an oxidizing substance, such as potassium bichromate, potassium permanganate, hydrogen peroxide, ozone, an image is not developed, but remains unaltered, showing that a change has been effected in the compound which under ordinary circumstances is developable. If such an oxidized salt be treated very cautiously with nascent hydrogen, the oxygen is withdrawn and the image is again capable of development.

Spectrum Effects on Silver Compounds. — The next inquiry is as to the effect of the spectrum on the different silver compounds. We have already described Seebeck's (1810) experiments on silver chloride with the spectrum whereby he obtained coloured photographs, but Scheele in 1777 allowed a spectrum to fall on the same material, and found that it blackened much more readily in the violet rays than in any other. Scheele's experiments have been already quoted. We merely mention these have become the foundation of nearly all subsequent researches of the same kind. The effects of the spectrum have been studied by various experimenters since that time, amongst whom we may mention Edmond Becquerel, John William Draper, Alphonse Louis Poitevin, H. W. Vogel, Victor Schumann and W. D. W. Abney. Fig. 1 is compiled from a cut which appeared in the Proc. Roy. Soc. for 1882, and shows the researches made by Abney as regards the action of the spectrum on the three principal haloid salts of silver. No. 7 shows the effect of the spectrum on a peculiar modification of silver bromide made by Abney, which is seen to be sensitive to the infra-red rays.

Effect of Dyes on Sensitizing Films. — In 1874 Dr H. W. Vogel of Berlin found that when films were stained with certain dyes and exposed to the spectrum an increased action on development was shown in those parts of the spectrum which the dye absorbed. The dyes which produced this action he called "optical sensitizers," whilst preservatives which absorbed the halogen liberated by light he called "chemical sensitizers." A dye might, according to him, be an optical and a chemical sensitizer. He further claimed that, if a film were prepared in which the haloid soluble salt was in excess and then dyed, no action took place unless some "chemical sensitizer" were present. The term "optical sensitizer" seems a misnomer, since it is meant to imply that it renders the salts of silver sensitive to those regions of the spectrum to which they were previously insensitive, merely by the addition of the dye. The idea of the action of dyes was at first combated, but was soon recognized that such an action did really exist. Abney showed in 1875 that certain dyes combined with silver and formed true coloured organic salts of silver which were sensitive to light; and Dr Robert Amory went so far as to take a spectrum on a combination of silver with eosin, which was one of the dyes experimented upon by J. Waterhouse, who closely followed Dr Vogel, and proved that the spectrum acted simply on those parts which were absorbed by the compound. Abney further demonstrated that, in many cases at all events, the dyes were themselves reduced by light, thus acting as nuclei on which the silver could be deposited. He further showed that even when the haloid soluble salt was in excess the same character of spectrum was produced as when the silver nitrate was in excess, though the exposure had to be prolonged. This action he concluded was due to the dye.

Correct Rendering of Colours in Monochrome. — In Plate II., fig. 14 the sensitiveness of a plate stained with homocollodion is shown, and it is evident that as it is sensitive throughout the visible spectrum there must be some means of cutting off by a transparent screen so much of the spectrum luminosity at different parts of the screen that your eye shall be shown on a negative of equal density. When this is done the relative luminosities of all the colours will be shown by the same relative densities or in a print by different depths of grey. By proper means the luminosity of the light of day coming through a red, a green, a blue and an orange glass can be very accurately measured; if ⅓-in. squares of these coloured glasses, together with a white glass of the same area, be placed in a row and cemented on white glass, we have a colour-screen which we can make available for finding the kind of light-filter to be employed. This is readily done by reducing the luminosity of the light coming through each small glass square to that of the luminosity of the light coming through the blue glass. If the luminosity of the blue be 5 and that of the white light 100, then the luminosity of the former must be reduced to ⅔ of its original value, and so with the other glasses. The luminosity of the light coming through each small glass square can be made equal by rotating in front of them a disk in which apertures are cut corresponding to the reduction required. The

blue glass, for instance, would not be covered by the disk at all, while opposite the white square the disk would have an aperture of an angle of 18°. When a plate is exposed behind the row of glass squares, with the light passing through the rotating disk, having the appropriate apertures for each glass, the negative obtained would under ordinary conditions, show square patches of very different opacity. A light-filter of some transparent colour, if placed in the path of the light, will alter the opacities, and eventually one can be found which will only allow such coloured light to be transmitted as will cause all the opacities in the negative to be the same. As the luminosities of the white light passing through the glasses are made equal, and as the photographic deposits are also rendered equal, this light-filter, if used in front of the camera lens, will render all coloured objects in correct monochromatic luminosity. Another plan, based on the same principles, is to place segments of annuluses of vermilion, chrome yellow, emerald green, French blue and white on a disk, and to complete the annuluses with black segments, the amount of black depending on the luminosity of the pigments, which can be readily measured. When the disk is rotated, rings of colour, modified in brightness by black, are seen, and each ring will be of the same luminosity. As before, a screen (light-filter) to be used in front of the lens must be found which will cause the developed images of all the rings to appear of equal opacity. It must be remembered that the light in which the object is to be photographed must be the same as that in which the luminosity of the glasses or pigments is measured.

**Action of the Spectrum on Chromic Salts.**—The salts most usually employed in photography are the bichromates of the alkalis. The result of spectrum action is confined to its own most refrangible end, commencing in the ultra-violet and reaching as far as in the solar spectrum. Fig. 2 shows the relative action of potassium and ferric chloride. If these two be brushed over paper, and the paper be then exposed to a bright solar spectrum, action is exhibited into the infra-red region. This is one of the few instances in which these light-waves of low refrangibility are capable of producing any effect. The colour of this solution is a muddy green, and analysis shows that it cuts off these rays as well as generally absorbs those of higher refrangibility.

**Action of Light on Uranium.**—The salts of uranium are affected by light in the presence of organic matter, and they too are only acted upon by those rays which they absorb. Thus nitrate of uranium, which shows, too, absorption-bands in the green blue, is affected more where these occur than in any other portion of the spectrum.

Some salts of mercury, gold, copper, lead, manganese, molybdenum, platinum, vanadium, are affected by light, but in a less degree than those which we have discussed. In the organic world there are very few substances which do not change by the continuous action of light, and it will be found that as a rule they are affected by the blue end of the spectrum rather than by the red end (see *Photochemistry*).

The following table gives the names of the observers of the action of light on different substances, with the date of publication of the several observations. It is nearly identical with one given by Dr Eder in his *Geschichte der Phot-Chemie*.

Fig. 2.—The top letters have reference to the Fraunhofer lines; the bottom letters are the initials of the colours. The relative sensitiveness is shown by the height of the curve above the base-line, the various parts of the spectrum on potassium bichromate. If other bichromates are employed, the action will be found to be tolerably well represented by the figures. No. 1 is the effect of a long exposure, No. 2 of a shorter one. It should be noticed that the solution of potassium bichromate absorbs those rays alone which are effective in altering the bichromate. This change is only possible in the presence of organic matter of some kind, such as gelatin or albumen.

**Action of the Spectrum on Asphalum.**—This seems to be continued into and below the red, the blue rays, however, are the most effective. The action of light on this body is to render it less soluble in its usual solvents.

**Action of the Spectrum on Salts of Iron.**—The commonest ferric salt in use is the oxalate, by which the beautiful platinitotype prints are produced. We give this as a representation (fig. 3) of the spectra obtained on ferric salts in general. Here, again, we have an example of the law that exists as to the correlation between absorption and chemical action. One of the most remarkable compounds of iron is that experimented upon by Sir J. Herschel and later by Lord Rayleigh, viz. ferrocyanide of iron, which is perfectly transparent to nearly all rays of the spectrum, and only absorbs those rays which are capable of breaking up the molecule, which is believed to be of the following form: Fe(NH₄)₅CN₃ Fe.

**Effect of Hydrogen Peroxide on Sensitive Plates.**—Dr. W. J. Russell made a series of experiments on the effect of exposure of sensitive plates to the action of vapours and gases for long periods. It has long been known that contact of plates with such substances as wood caused a sensitive surface to show "fog" on development. By a somewhat exhaustive series of experiments, Russell showed that the probable cause of this fog is hydrogen peroxide, since substances which favoured its formation produced the same effect. This is somewhat remarkable, as this same substance will completely destroy the effect that light had had on a sensitive plate; indeed, it affords one way of destroying a light image on a sensitive collodion plate. The experiments of Russell give a warning to store exposed plates for long periods. It appears that negatives wrapped in paraffin paper are secure from this danger.

**The Application of Photography to Quantitative Measures.**—In order to employ photography for the measurement of light it was necessary that some means should be devised by which the opacity of the deposit produced on the development of a plate could be determined. It is believed that in 1874 the first attempt was made by Sir W. Abney to do this. In the *Phil. Mag.* he showed how density could be measured by means of an instrument, the diaphanometer, he had devised, in which transparent
PHOTOGRAPHY

499

The black wedges were used to make matches between the naked light and the same light after passing through the photographic opacity that had to be measured. In 1857, owing to the perfecting of the rotating sectors, which could be made to increase or diminish the apertures at pleasure during its rotation, the measurement of opacities became easy. The Rumford method of comparing the light through the deposit with that of a beam, using the sectors to equalize the illumination, was adopted, if the position of the light and the screen, the comparison light being a beam reflected from the same light on to the screen.

Owing to the fact that photographic deposit scatters light more or less, the opacities measured by this plan were slightly greater than those of the exposed plates used for contact printing. The final plan adopted by Abney was to place the part of the plate carrying the deposit to be measured behind a screen constructed as above. C D (fig. 4) is a plate, A B the same size as C D, but pasted on the black card itself. Light thrown from behind A would be matched with light thrown on to B from the front when a rod in the path of this last beam was made to prevent this light falling on A. When a portion of a plate bearing a deposit was placed behind and close to A, the light thrown on B had to be diminished by the second, till the two squares appeared equally bright; and the aperture of the sector was noted and compared with that required when the deposit was removed.

With this screen accurate measures of printing densities can be made, and it can also be used in the determination of the comparative photographic brightness of the light issuing from different objects. For instance, the relative brightness of the different parts of the corona as seen in a total eclipse can be readily determined if a "time scale" of gradation is impressed on the plate on which it is taken. Both scale and streamer can be enlarged optically and thrown on the part of the screen A. The measures of the streamer densities can then be compared with the densities of the scale and the relative "photographic" brightness of the different parts of the streamer be ascertained by comparison with this scale also.

The same method of measurement was adopted in ascertaining quantitatively the sensitiveness of the spectrum of ordinary plates and of plates in which dyes are present. The figures on pl. IV show reproductions of plates which were exposed to the spectrum. No. 1 is a continuous spectrum taken with the electric light; no. 7 is an impressed continuous spectrum; no. 8 shows the bright lines of metals; no. 3 the line spectrum of volatilized lithium and sodium to indicate the position of the spectrum colours. Nos. 4 and 2 are the absorption and fluorescent spectra of eosin. No. 5 is the graduated scale formed by a bromogelatin "Seed" plate stained with hemocryl, a cyanine derivative sensitive to the red; no. 6 is a similar scale formed by an unstained plate. The small numbers placed below the different bands show an empirical scale which is made to apply to each of them. The first step is to measure

different parts, and also the curve of sensittiveness of the plate to the different parts of the spectrum. This last is derived from a comparison of the measured densities with those of the gradation scale.

Measurement of the Rapidity of a Plate.—The first attempt that was made to ascertain the rapidity of a plate was by Abney (Phil. Mag. 1874), who demonstrated that within limits the transparency of deposit varied as the logarithm of the exposure.

The last formula has been accepted for general use, though it is believed that it is not absolutely correct, though very approximation and sufficiently accurate for practical purposes.

If in a straight line be the time of exposure, and the intensity of light acting, and C a constant. If the abscissae (exposures) are plotted as logarithms, the curve takes the same form as that of the law of error, which has a singular point, a tangent through which closely lies along the curve, and cuts the axis of Y at a point which has a value of $\frac{1}{2}$ in. If the total transparency be unity, this ordinate has a value of 1:12, the singular point having a value of 0:606. The ordinate of the zero point of the curve will be where the tangent to the singular point cuts the line drawn at 1:12. The difference between the measurements of this zero point for two kinds of plates (i.e. C in the formula) from the points in the photographic chart marking the extreme exposures is a measure of the sensitiveness of the two plates in terms of log $\times$. In 1890 Hurter and Driffield (Journ. Soc. Chem. Ind. Jan. 19, 1891) worked out a less empirical formula connecting the exposure E with the density D of the deposit, for which the curve is of the form in which D is the density of deposit (or log 1/T), i.e. the "inertia" of the plate, T the transparency of the deposit. In the customary way a plate has a "zero point" where the deposit is exposed to a constant light at a fixed distance and for a fixed time, and another small portion to the same light for double the time, and so on. By measuring the densities of the various deposits and constructing a curve, a large part of which was approximately a straight line, it was found possible, by the production of the straight portion to meet the axis of X, to give the relative sensitiveness of different plates by the distance of the intersection from the zero point. L. (See also Exposure Meter, under § l. Appendix.)

Effect of Temperature on Sensitiveness.—In 1876 Abney showed that heat apparently increased, while cold diminished, the sensitiveness of a plate, but the experiments were rather of the qualitative than the quantitative order. In 1893, from fresh experiments, he found that the effect of a difference in temperature of some 40° C. invariably caused a diminution in sensitiveness of the sensitive salt at the lower temperature, a plate often requiring more than double the exposure at a temperature of about 18° C. than it did when the temperature was increased to +33° C. The general deduction from the experiments was that increase in temperature involved increase in sensitiveness so long as the constituents of the plate (gelatin, &c.) were unaltered. Abney, Proc. Roy. Soc. 1893.

Royal Institution in 1896 that at a temperature of 290° C. certain sensitive salts were reduced in sensitiveness to less than a quarter of that which they possess at ordinary temperatures. It appears also, from his subsequent inquiry, that when the same films were subjected to the temperature of liquid hydrogen (−259° C.) the loss in sensitiveness becomes asymptotic as the absolute zero is approached. Presumably, therefore, some degree of sensitiveness would still be preserved even at the absolute zero.

Effect of Small Intensities of Light on a Sensitive Salt.—When a plate is exposed for a certain time to a light of given intensity, it is commonly said to have received so much exposure (E). If the time is altered, as the intensity of the light also, so that the exposure (time $\times$ intensity) is the same, it was usually accepted that the energy expended in doing chemical work in the film was the same. A series of experiments conducted under differing conditions has shown that such is not the case, and that the more intense the light (within certain limits) the greater is the chemical action, as shown on the development of a plate. Fig. 6 illustrates the results obtained in three cases. The exposure E is the same in all cases. The curves are so drawn that the scale of absissees represents the time, and the intensities vary along the horizontal axis.
is the intensity of the light in powers of $-2$, and the ordinates show the percentages of chemical action produced. If the chemical action remained the same when the intensity of light was reduced, $E$ remaining the same, each of the curves would be shown as a straight line at the height of 100, which is the transparency of deposit with the unit of light. As it is, they show diminishing percentages as the light intensity is diminished.

![Diagram of Transparency and Intensity](image)

**Fig. 6.**

Thus, when the intensity of the light is reduced to $\frac{1}{2}$ of the original, and the time of exposure is prolonged 64 times, the useful energy expended on a lantern plate is only 50% of that expended when the light and time of exposure are each unity. In the cases to which the diagram refers, the light used was a standard amyl acetate lamp, and the unit of intensity taken was this light at a distance of 2 ft. from the plate, and the unit of time was 19 seconds. The lamp being moved to 16 ft. from the plate, gave an intensity of $\frac{1}{4}$ the unit, and the time of exposure had to be increased to 640 seconds, so that $E$ was the same in both cases. Further, it was found that when the times of exposure on different parts of the plate were successively doubled, light at a fixed distance being used for one series, and altered for a second series, the slopes of the curves of transparency (i.e. the gradation) were parallel to one another. This investigation is of use when camera images are in question, as the picture is formed by different intensities of light, not very different from those of the amyl acetate lamp, the time of exposure being the same for all intensities. The deductions made from the investigation are that with a slow plate the energy expended in chemical action is smaller as the intensity is diminished, while with a quick plate the variation is much less. As a practical deduction, we may say that to obtain proper contrast in a badly lighted picture it is advisable to use a slow plate.

**Effect of very Intense Light on a Sensitive Salt.** Another investigation was made as to the effect of very intense light on sensitive surfaces. In this case a series of step-by-step graduated opacities was used made of, and plates exposed through it to the action of lights markedly differing in intensity, one being that of the amyl acetate lamp, another that of the arc light, and a third the light emitted from the spark of a Wimshurst machine. The exposures were so made that one of the opacities produced on the plate from exposure to each source of light was approximately the same. The unit of intensity of light is, of course, in each case widely different. The slope of the curve due to the spark light is less steep than that due to the arc light, and the latter, again, is much less steep than that due to the amyl acetate lamp. A further investigation was made of the effect of increasing the time of exposure when the intensity was diminished, and it was found that with all plates the useful chemical energy acting on a plate was least with the most intense light, but increased as the intensity diminished, though the time was correspondingly increased. This is the reverse of what we have recorded as taking place when a comparatively feeble light was employed. Further, it was proved that the variation was greatest in those plates which are ordinarily considered to be the most rapid. It follows, therefore, that there is some intensity of light when the useful chemical energy is at a maximum, and that this intensity varies for each kind of plate.

**Intermittent Exposure of a Sensitive Salt.** The same investigator has shown that, if a total exposure is made up of intermittent exposures, the chemical action on a sensitive salt is less than it is when the same exposure is not intermittent. It was also proved that the longer the time of rest between the intermittent exposures (within limits) the less was the chemical action. We may quote one case. Exposures were first made to a naked light, and afterwards to the same light for six times longer, as a rotating disk intervened which had 12 apertures of $\frac{1}{6}$ cut in it at equal intervals apart, and 72 intermittent exposures per second were given. The plate was moved to different distances from the light, so that the intensity was altered. The apparent loss of energy by the intervention of the disk increases as the intensity diminishes, the ratio of the chemical energy usefully employed of the naked light exposure to that of the intermittent exposures being:

These results appear to be explicable by the theoretical considerations regarding molecular motion.

**Effect of Monochromatic Light of Varying Wave-lengths on a Sensitive Salt.** It has been a subject of investigation as to whether the gradation on a plate is altered when exposures are made to lights of different colours; that is to say, whether the shades of tone in a negative of a white object illuminated by, say, a red light, would be the same as those in the negative if illuminated by a blue light. Abney announced that the gradation was different; and, quite independently, Chapman Jones made a general deduction for isochromatic plates that, except with a certain developer, the gradation was steeper (that is, the curve shown graphically would be steeper) the greater the wave-lengths of the light to which the sensitive salt was subjected. For plates made with the ordinary haloid salts of silver Chapman Jones's deduction requires modification. When monochromatic light from the spectrum is employed, it is found that the gradation increases with wave-lengths of light which are less, and also with those which are greater, than the light whose wave-lengths has a maximum effect on the sensitive salt experimented with. Thus with bromo-iodide of silver the maximum effect produced by the spectrum is close to the blue lithium line, and the gradation of the plate illuminated with that light is less steep than when the light is spectrum violet, green, yellow or red. From the red to the yellow the gradation is much the steepest. Whether these results have any practical bearing on ordinary photographic exposures is not settled, but that they must have some decided effect on the accuracy of three-colour work for the production of pictures in approximately natural colours is undoubted, and they may have a direct influence on the determination of star magnitudes by means of photography.

**Reproduction of Coloured Objects by means of Three Photographic Positives.**—Ives Process. A practical plan of producing images in approximately the true colours of nature has been devised by preparing three positives of the same object, one

illuminated by a red, the other by a green, and the third by a blue light; the images from these three transparencies, when visually combined, will show the colours of the object. This plan was scientifically and practically worked out by F. E. Ives of Philadelphia, though in France and elsewhere it had been formulated, especially by Aauron Du Clos.
